PUBLISHER'S PREFACE.

SINCE the first Part of NICHOLSON'S "DICTIONARY OF GARDENING" first saw the light, great changes have been brought about—changes which demand to be recognised in a work such as this aims to be. In nomenclature alone they have been exceedingly numerous, and plant names which had become almost household words have now been usurped by others unknown to any but botanists. Familiar examples of such changes may be cited in the Pampas Grass, formerly *Gynerium argenteum*, but now *Cortaderia argentea*, and in *Ampelopsis tricuspidata* (SYN. *A. Veitchii*), now known as *Vitis inconstans*.

In Horticultural practice a more extended experience with certain plants has resulted in the overthrow of some of the long-cherished notions entertained in regard to their treatment, necessitating some considerable modifications. And in no section perhaps is this more clearly shown than in Orchids on the one hand, or in Fruit Culture, both out of doors and under glass, on the other.

Certain groups of plants, like most other things, have had their day. Old favourites have gone and new ones have taken their place. Their prominence for the time may be due to Fashion alone; or it may be, and still oftener is, due to the fact that the florist has really improved upon existing forms by producing something of still greater beauty and of more robust constitution, or has introduced something new of great merit. Who, for instance, twenty years ago could have foretold the advent of the beautiful, if over-named, Hybrid Water-Lilies associated with M. MARLIAC? Or, again, who could have anticipated those beautiful additions to our outside gardens, the Hardy Bamboos, for whose introduction we owe so much to Mr. FREEMAN MITFORD?

Considerable progress has been made in what are termed Florists' Flowers—Dahlias, Roses, Violas, Carnations, Gladioli, Narcissi, &c.—and these plants of to-day are vastly different from those of the time of the first publication of the "DICTIONARY OF GARDENING"; and life-histories of Insects and Mites, as well as of Parasitic Fungi, have been so accurately worked out by entomologists and plant-pathologists that the methods of dealing with foes generally have been considerably improved upon.

The above are suggestive of some of the many and great changes which have taken place in the last two decades. How best to adequately deal with them, in

JUL 19 1950

a manner at once consistent with the reputation of the "DICTIONARY OF GARDENING" for thoroughness, and fair to subscribers, has been the earnest consideration of the Publisher. Eventually it was decided that the best way of meeting the difficulty was to issue a Supplemental Volume, to include all additions and modifications that Time has rendered necessary, thus bringing the entire work right up to the present time, without decreasing, but, on the contrary, increasing, the value of the volumes already in the hands of subscribers; for it must be remembered that the great bulk of the subscribers are working gardeners, to many of whom the purchase of the work has represented great personal sacrifice, and to whom its supersession by the issue of a new edition would have been a very grievous loss.

During the progress of the present volume through the Press there have been one or two important changes that unfortunately could not be noted in their proper places, owing to the fact that they were not made known until some time after the portion of the work to which they referred was printed. One of these is in connection with *Phaius tuberculosus* (Blume) [SYN. *Limodorum tuberculosum* (Thouars)]. Quite recently a terrestrial species was introduced for the first time that appears to be identical with the original plant of Thouars. The epiphytal species known in gardens under the above name, and figured as such in many works, is not, according to Mr. Rolfe, the original plant, and it has been named by him *P. simulans*, because of the remarkable resemblance the flowers bear to those of the original species.

As in the previous volumes, BENTHAM AND HOOKER'S great work, the "Genera Plantarum," has been made the basis of generic limitation, aided by such Monographs and Floras as have been recently published, together with the excellent series of Kew Handbooks, and of course the "Index Kewensis." To the synonymy due attention has been paid, though naturally with such a vexed question there is plenty of room for diversity of opinion.

To those eminent Specialists whose names appear on the title-page we offer our grateful thanks for valuable contributions and generous assistance at all times when asked; and we desire also to cordially acknowledge our indebtedness to Mr. W. BAKER-BARTLETT for his indefatigable exertions in matters of general research so little observed by the public eye, yet so important in a work like this.

Though the scholarly aid that the late Rev. PERCY MYLES gave in the matter of plant-name etymology has not been available for the present volume, we have been fortunate in receiving invaluable aid in this department from Mr. C. H. WRIGHT, of Kew. To several gentlemen and firms, notably Messrs. VEITCH AND SONS, Messrs. SANDER AND SONS, and Messrs. BARR AND SONS, as well as to the "Gardeners' Chronicle," we are indebted for the loan of illustrations, or photographs from which to prepare them; and our indebtedness is very great to Mr. R. I. MEASURES for many beautiful photographs, and especially for the charming drawing for the coloured illustration of *Epiphronitis Veitchii*.

LONDON.

REFERENCE TO ILLUSTRATIONS OF PLANTS OTHER THAN THOSE FIGURED IN THIS WORK.

MANY readers will be glad to be informed where reliable Illustrations can be found of those Plants which are not figured in this Work. To meet this want, references to the Figures in Standard Authorities have been given, the titles of the Works referred to being, for economy of space, abbreviated as follow:

A. B. R. .. Andrews (H. C.). Botanist's Repository. London, 1799-1811. 10 vols. 4to.

A. E. .. .. Andrews (H. C.). Coloured Engravings of Heaths. London, 1802-30. 4 vols. 4to.

1900 SUPPLEMENT

TO THE

DICTIONARY OF GARDENING.

GIVING PARTICULARS OF RECENT INTRODUCTIONS AND THE MOST MODERN METHODS OF CULTIVATION, DISCOVERIES IN THE MATTER OF PLANT DISEASES AND PESTS, &c., AND ALL ELSE CONNECTED WITH THE ADVANCE OF THE SCIENCE OF HORTICULTURE.

The following are the abbreviations used:—*fl.* flowers; *fr.* fruit; *l.* leaves; *h.* height; *deg.* degrees; *rhiz.* rhizomes; *cau.* caudex; *sti.* stipes; SYN. Synonym; ORD. Natural Order.

The Asterisks (*) indicate plants that are especially good or distinct.

ABAMA. A synonym of **Narthecium** (which *see*).

ABELIA. This genus embraces about half-a-dozen species, natives of the Western Himalayas, China, Japan, and Mexico. To those described on p. 1, Vol. I., the following should be added:

A. chinensis (Chinese).* The correct name of *A. rupestris* (of gardens). The garden variety *grandiflora* has large, pinkish-white flowers, and the whole plant is more vigorous than the type. It is a seedling of Italian origin. SYN. *A. uniflora.*

A. spathulata (spathulate). *fl.* sessile, in pairs on a short, slender peduncle; corolla white, with yellow blotches on the throat, nearly 1in. long. April. *l.* about 2in. long, elliptic-lanceolate, obtusely acuminate, sinuate-toothed, glabrous above, pubescent beneath, edged purple. Japan, 1883. A free-flowering, much-branched, evergreen shrub. See Fig. 1. (B. M. 6601.)

A. uniflora (one-flowered). (B. M. 4694; P. F. G. ii. 145.) A synonym of *A. chinensis.*

ABELICEA. A synonym of **Zelkova** (which *see*).

ABELMOSCHUS. Included under **Hibiscus** (which *see*).

ABENA. A synonym of **Stachytarpheta** (which *see*).

ABIES. SYN. *Picea* (of Don). For park decoration the genus *Abies* affords some of the most striking examples to be met with in the order *Coniferæ.* All are hardy, but on account of the liability of some species and varieties to push their growth very early in the year, they not infrequently get "cut." Landscape gardeners get over this difficulty by planting such precocious kinds in more exposed positions than would be assigned those which are not so early to make a start. *A. bracteata*, *A. cephalonica*, and *A. Webbiana* are familiar examples of trees with the tendency just alluded to. Taken as a whole the members of this genus are best planted where they are sheltered from cutting winds and in a good loam and leaf mould, with ample drainage. A moist position is best suited to some species, so long as the drainage is good, and especially so to *A. brachyphylla.*

To the species described on pp. 1-2, Vol. I., the following should be added:

A. Alcockiana (Alcock's), of gardens. A synonym of *Picea ajanensis.*

FIG. 1. ABELIA SPATHULATA.

Abies—*continued.*

FIG. 2. ABIES LOWIANA (Young Plant).

A. bifolia (two-leaved), of A. Murray. A synonym of *A. lasiocarpa.*

A. bifolia (two-leaved), of Siebold and Zuccarini. A synonym of *A. firma.*

A. brachyphylla (short-leaved), of Mayr. A synonym of *A. homolepis.*

A. campylocarpa (bent-fruited). A synonym of *A. magnifica.*

A. chiloensis (Chiloe). A synonym of *A. Webbiana.*

A. concolor violacea (violet). *l.* of a bluish-glaucous tint. A charming variety.

A. Eichleri (Eichler's). A synonym of *A. Veitchii.*

A. Gordoniana (Gordon's). A synonym of *A. grandis.*

A. grandis Lowiana (Low's). A synonym of *A. Lowiana.*

A. g. pendula (pendulous). A weeping form, which originated in a Berlin nursery.

A. holophylla (wholly-leafy). A synonym of *A. firma.*

A. homolepis (similar-scaled). *l.* axillary, 1in. long, somewhat two-rowed, very thickly placed, linear, flat, obtuse or bifid at apex, somewhat falcate; petioles very short. *cones* 3in. long, 1in. broad, cylindrical, obtuse, usually straight, on short stalks; scales brown, thickly imbricated. *h.* 100ft. Japanese Islands, 1861. SYN. *A. brachyphylla* (of Mayr).

A. Kæmpferi (Kæmpfer's). A synonym of *Pseudolarix Kæmpferi.*

A. lasiocarpa (woolly-fruited). *l.* notched on the barren and pointed on the fertile branches, in many rows, with two glaucous bands on the lower side. *cones* 2in. to 3½in. long, 1in. to 1½in. thick, with rounded scales. British Columbia, &c. Allied to *A. balsamea*, but larger, and having whitish bark. (G. C. 1889, v., p. 172, f. 23-32.) SYNS. *A. bifolia* (G. C. 1875, p. 465, f. 96-7), *A. subalpina* (G. C. 1880, p. 235, f. 43-45; J. L. S. xxii., p. 185).

A. Lowiana (Low's). *l.* long, linear, flat, straight, 1½in. to 2½in. long, one line broad, channelled above, twisted at base, distant, disposed in two horizontal rows along the shoots, blunt or slightly

Abies—*continued.*

notched at apex, dull glaucous-green above, paler beneath. *cones* 3½in. to 5in. long, 1½in. broad, erect, cylindrical, obtuse, rounded at base, pale brown. *h.* 250ft. Northern California, &c. Branches rather pendulous. A very handsome tree. See Fig. 2. (G. C. Dec. 11, 1886, p. 755, f. 143; 1890, Dec. 27, p. 750.) SYNS. *A. grandis Lowiana* (J. L. S. xxii., p. 175), *Picea Lowiana.*

A. magnifica xanthocarpa (yellow-fruited). *l.* on the leader shoot spirally appressed; those on the lateral shoots upturned, ascending; those on the sterile branches slender, straight or curved, more or less four-sided in section, grooved at base on the upper surface; those on the fertile branches stouter, shorter, all upturned, four-sided, not grooved. *cones* ovate-oblong, obtuse. SYNS. *A. nobilis robusta* (G. C. 1885, **xxiv.**, p. 657, f. 147), *A. shastensis.*

A. nephrolepis (reniform-scaled). A synonym of *A. Veitchii.*

A. nobilis robusta (robust). A synonym of *A. magnifica xanthocarpa.*

A. Nordmanniana. An illustration of this admirable tree for the lawn or park is given in Fig. 3.

A. N. horizontalis (horizontal). A dwarf, compact-growing form, with horizontally spreading branches; it cannot be made to produce a leader, hence its peculiar habit. A chance seedling found in a nursery in the Vosges.

A. N. pendula (drooping). A garden variety, distinguished from the type in having drooping branches. 1869. (R. H. 1890, p. 440, f. 182.)

A. numidica (Numidian). The correct name of *A. baborensis* (G. C. Feb. 4, 1888, p. 140, f. 23).

A. polita. The correct name is *Picea polita.*

A. shastensis (Shasta). A synonym of *A. magnifica xanthocarpa.*

A. subalpina is synonymous with *A. lasiocarpa.*

FIG. 3. ABIES NORDMANNIANA.

Abies—*continued.*

A. Webbiana obovata (obovate). This differs from the type mainly by the snowy whiteness of the under-surface of its leaves, which are deep green above

Pests. In common with many other Conifers, Abies are liable to attack from a host of Fungi, Beetles, Sawflies, and other insects, and suffer considerably therefrom. The most destructive will be found dealt with under the heading FUNGI in the genus **Pinus, Pine Bark Beetle, Pine Sawflies,** and **Pine Weevils** in the old volumes, and under **Agaricus, Polyporus, Oospora, Silver-Leaf Disease,** and **Æcidium** in the present one.

ABIES (of Don). A synonym of **Picea** (which *see*).

ABOBRA. *A. tenuifolia* is the name adopted by Cogniaux for *A. viridiflora* (described in Vol. I.); it is the only species of the genus.

ABOLARIA. A synonym of **Globularia** (which *see*).

ABROMA. About two or three species, natives of tropical Asia, Australia, &c., are included in this genus. Flowers dingy purple; calyx five-parted; petals five, with dilated claws, and ovate, spreading laminæ; peduncles opposite the leaves or almost terminal, few-flowered. Leaves palmately lobed or entire. To the species described on p. 3, Vol. I., the following should be added:

A. sinuosa (sinuate). *l.* broadly ovate, pedately pinnatifid, on slender petioles. Madagascar, 1884. A pleasing species, of slender habit.

ABRONIA. SYN. *Tricratus.* This genus includes about ten species. To those described on p. 3, Vol. I., the following should be added:

A. Crux-maltæ (Maltese Cross). *fl.* of a deep purplish-pink, the swollen throat of a bright emerald-green, the limb in general outline bearing a striking resemblance to a Maltese cross; heads axillary, ten to fifteen-flowered. *l.* ovate-oblong, somewhat obtuse, acute at base, on long petioles. Stem "a creeping vine," viscid-pubescent. California.

A. latifolia (broad-leaved). *fl.* yellow, about ½in. across, borne on very long peduncles; involucre two- or three-lobed. August. *l.* very variable in shape, but always much broader than long, borne on long petioles. Stem 6in. to 12in. long, procumbent, almost woody, terete. California. Whole plant glutinous. (B. M. 6546.)

A. mellifera (honey-bearing). *fl.* orange, in loose clusters; limb five-lobed; peduncles 4in. to 6in. long. July. *l.* ovate or ovate-oblong, oblique, fleshy, slightly sinuated, borne on long petioles. Stem decumbent. California and Mexico, 1826. (B. M. 2879.)

ABRUS. Wild Liquorice. Bentham and Hooker include five species under this genus, dispersed over the warmer regions of the globe; they are shrubs or sub-shrubs, often with long-twining branches. Flowers small, pinkish or whitish, racemes terminal, or the short flowering branchlets axillary; standard ovate; wings narrow.

ABSINTHIUM. Included under **Artemisia** (which *see*).

ABUMON. A synonym of **Agapanthus** (which *see*).

ABUTA. About half-a-dozen species, natives of tropical America, are referred to this genus. Sepals six, in two or three series, the outer ones small and bract-like; petals wanting; stamens six. Leaves coriaceous, three- to five-nerved, the nerves elevated beneath.

ABUTILON. This genus embraces about seventy species of herbs or shrubs, rarely trees, often softly tomentose, inhabiting the warmer regions of the globe. Flowers usually axillary, variously coloured, but often yellow; bracteoles wanting. Leaves often cordate, angled or lobed, rarely narrow. To the species and varieties described on pp. 4-5, Vol. I., the following should be added:

A. aurantiacum (orange). *fl.* axillary and solitary; calyx villous-pubescent; corolla bright orange, ¼in. to ⅜in. long. *l.* densely soft-tomentose, velvety, whitish, round-cordate, acute, ¼in. to 1¼in. broad, the basal lobes overlapping. Stems 6in. to 2ft. high. California.

Abutilon—*continued.*

A. esculentum (edible). *fl.* purple, axillary, solitary. September. *l.* cordate, acuminate, toothed, puberulous above, tomentose beneath. Stem tomentose with grey hairs. *h.* 7ft. to 8ft. Rio Janeiro, 1830. The natives cook and eat the flowers under the name of Bencao de Deos.

A. graveolens (strongly-scented). *fl.* orange and red, rather large, on pedicels about as long as the petioles. *l.* broadly orbicular-cordate. *h.* 1ft. to 5ft. Australia, 1842. A coarse annual or perhaps perennial, clothed with a viscid, strongly-scented tomentum.

FIG. 4. ABUTILON INSIGNE.

A. insigne (remarkable). The flowers of this are of a lovely rose, with darker veinings. See Fig. 4.

A. integerrimum (entire). *fl.* yellow, large, showy; petals broadly obovate-cuneate, oblique, distant, spreading, with an orange spot at base. May. *l.* large, orbicular-cordate, shortly acuminate, entire, on long petioles. Colombia. A small tree. SYN. *Sida integerrima.* (B. M. 4360.)

A. Thompsoni flore-pleno (double-flowered). A garden variety with double flowers. 1885. Greenhouse. (R. H. 1885, p. 324.)

A. vitifolium album (white). A variety with pure white flowers. 1889.

VARIETIES.—The following selection includes most of the best of the newer varieties having their origin in gardens. The majority are hybrids:—

CALYPSO, pure white, large. CAPRIVI, deep red, large. CHAMELEON, crimson. CHRYSOSTEPHANUM COMPACTUM, chrome-yellow; excellent for bedding. CLOTH OF GOLD, clear yellow; flowers large and bell-shaped, with overlapping petals. FLORIBUNDUM, orange-red, with darker veins. LE GRAND, deep red, with darker veins. MADAME JOHN LAING, rose, very large. Mr. H. CANNELL, a free-flowering hybrid from *A. megapotamicum.* MISS L. POWELL, yellow, dwarf. MR. WILLIAM BULL, fawn, veined crimson. PREMIER, rosy-purple, large. PRINCE OF ORANGE, orange. ROYAL SCARLET, red scarlet. SOUVENIR DE BONN, leaves rich green, margined with white. SURPRISE, golden yellow, veined red. WISSMANN, orange-buff, veined crimson.

ACACALLIS (derivation of name uncertain). ORD. *Orchideæ.* A monotypic genus. The species is a stove, epiphytal Orchid, with a short, leafy stem, at length thickening into a pseudo-bulb; it is distinguished from *Aganisia* by the curious appendage to the lip and by the

Acacallis—*continued.*

large auricles of the column. According to Messrs. Veitch, it requires to be grown in the highest temperature available in our Orchid-houses. On account of its climbing habit, it should be affixed to a block or raft; in other respects it will thrive under the ordinary East Indian house treatment.

A. cyanea (blue). The correct name of *Aganisia cærulea* (W. O. A. viii. 374).

ACACIA. Including *Farnesia.* In the "Genera Plantarum" about 420 species are allotted to this genus; they are dispersed over the warmer parts of the world, but are especially plentiful in Australia and in Africa. Sepals five, four, or three, free or united; petals as many, free or united; stamens indefinite, usually very numerous, free or slightly connected at the very base. Pods linear or oblong, flat or nearly cylindrical, straight, falcate, or variously twisted, opening in two valves or indehiscent. Leaves bipinnate; leaflets often small and many-jugate, or reduced to a filiform petiole (phyllode). To the species described on pp. 5-7, Vol. I., the following should be added. The hardy deciduous tree called *Acacia* in gardens is **Robinia Pseudacacia.** *See also* **Albizzia.**

A. Baileyana (Bailey's). *fl.* in small, globose heads, arranged in erect, loose racemes. Winter. *fr.*, pods long, linear-oblong. *l.* stalked, bipinnate; pinnæ consisting of small, linear leaflets. New South Wales and Queensland. (G. C. 1894, xv., p. 37, f. 4.)

A. coccinea (scarlet). A garden synonym of *Ormosia coccinea.*

A. cordata (heart-shaped). A garden synonym of *A. hastulata.*

A. cornigera (horn-bearing). A synonym of *A. spadicigera.*

A. floribunda (abundant-flowered), of Willdenow. A synonym of *A. angustifolia.*

A. floribunda, of gardens. A synonym of *A. retinodes.*

A. hastulata (somewhat hastate).* *fl.*, peduncles short and slender, each bearing a head of three to five flowers, mostly four-parted. May. *l.*, phyllodia numerous, hastate-lanceolate or almost cordate, tapering into pungent points, two or three lines long, with one central nerve. Branches rather slender, virgate or divaricate, terete. *h.* 2ft. to 3ft. Western Australia, 1824. (B. M. 3341.) SYN. *A. cordata* (of gardens).

A. Lebbek (Lebbek). The correct name is now *Albizzia Lebbek.*

A. leprosa (leprous).* *fl.* numerous in a globular head, mostly five-parted; petals yellow, united to the middle. May. *l.*, phyllodia narrow, linear-lanceolate, acute, or obtuse with a small point, narrowed at base, 1½in. to 3in. long. Branchlets pendulous, more or less glutinous. Australia, 1817. A tall shrub or small tree. (B. R. 1441.)

A. lineata (lined). *fl.* ten to fifteen or more in a small, globular head, mostly five-parted; petals yellow, smooth. April. *l.*, phyllodia linear, with a small, hooked point, usually ½in. to ¾in. long. Branches pubescent or villous, sometimes slightly resinous. *h.* 6ft. Australia, 1824. (B. M. 3346.)

A. Nemu (Nemu). A synonym of *Albizzia Julibrissin.*

A. obliqua (oblique). A synonym of *A. rotundifolia.*

A. petiolaris (petiolate). A synonym of *A. pycnantha.*

A. pycnantha (dense-flowered). *fl.* mostly five-parted; racemes short, with a few dense, globular heads of fifty to one hundred flowers. *l.*, phyllodia lanceolate-falcate, obtuse or rather acute, much narrowed to the base, 3in. to 6in. long. Victoria. A small or medium tree. SYN. *A. petiolaris.*

A. retinodes (retained). *fl.* mostly five-parted; racemes much shorter than the phyllodia, branched, with several (sometimes twenty) globular heads of twelve to twenty flowers. March. *l.*, phyllodia linear-lanceolate, falcate, much narrowed towards the base, mostly 3in. to 5in. long, finely penni-veined. Victoria. A moderate-sized tree. SYN. *A. floribunda* (of gardens).

A. spadicigera (spadix-bearing). *fl.* greyish and yellowish, forming cylindrical, spadix-like heads 1in. or more in length, disposed in axillary clusters. *l.* bipinnate; pinnæ four to eight pairs; leaflets fifteen to twenty pairs, linear-oblong, obtuse. Spines large, horn-like. Central America and Cuba, 1692. One of the so-called Bull's-horn Acacias; its hollow spines are tenanted by stinging ants. (B. M. 7395.) SYN. *A. cornigera.*

ACÆNA. New Zealand Bur. SYN. *Ancistrum.* This genus includes about thirty species of decumbent or somewhat creeping herbs, often shrubby at the base, the floriferous branches often erect and scape-like; they are distributed over the temperate and frigid parts of the Southern Hemisphere, being often found in Chili and Peru. To their value as rock-plants must be added their utility for growing under trees—and trees, too, like Conifers, beneath which scarcely anything will survive. The species *A. microphylla, A. myriophylla,* and *A. pulchella* may all be so utilised. To those described on p. 7, Vol. I., the following should be added:

A. adscendens (ascending). *fl.* dark purple; heads globose, borne on long peduncles. *l.*, leaflets ¼in. to 1in. long, obovate or elliptic-obovate, obtuse, toothed, glabrous above, silky beneath. Stems long-creeping, with ascending branches. Patagonia, 1888.

A. cuneata (wedge-shaped). A synonym of *A. sericea.*

A. ovina (egg-like). *fl.* purple, in long, interrupted spikes, denser towards the end. *l.* rather long; leaflets elliptic obtuse, pinnately cut to the middle, more or less pubescent on both sides or glabrous above. Australia, 1888. This is similar to *A. ovalifolia,* but it is a little larger and less graceful.

A. pinnatifida (pinnately-cleft). *fl.* crowded into cylindrical spikes, the lower ones rather remote. May and June. *l.* consisting of three to five pairs of deeply three- to five-parted leaflets; segments linear. Stem erect. *h.* 6in. Chili and Magellan Straits, 1822. Half-hardy perennial. (B. R. 1271.)

A. repens (creeping). A synonym of *A. sarmentosa.*

A. Sanguisorbæ (Sanguisorba-like). *fl.* in globose heads, ¼in. to ½in. in diameter; scapes slender, two-leaved. *l.* 2in. to 6in. long; leaflets eight to ten pairs, very variable in shape, membranous, coarsely serrated, ¼in. to ⅝in. long. New Zealand. A much-branched, prostrate herb, more or less silky, especially on the nerves beneath.

A. sarmentosa (having runners). *fl.* in globose heads, on tomentose peduncles of moderate length, with one or two bracts. Tristan d'Acunha, 1888. A rampant species, similar to *A. Sanguisorbæ,* but stouter, with longer branches, leaves more silky beneath and longer hairs. "Perhaps the plant in cultivation is not correctly named, as it is said to come from South America" (N. E. Brown).

A. sericea (silky).* *fl.* green, in globose heads, on long peduncles, which also bear two or three smaller heads, sessile in the axils of leafy bracts. *l.* rather long; leaflets only three to five pairs, cuneate-oblong, toothed, silky beneath. Patagonia and Chili, 1888. SYN. *A. cuneata.*

A. splendens (splendid). *fl.* in long, interrupted spikes, borne on long, stout peduncles. *l.*, leaflets three or four pairs, obovate or ob lanceolate, toothed, densely white-silky on both sides. Chili, 1888

ACALYPHA. SYN. *Cupameni.* This genus comprises about 220 species, broadly dispersed over the warm

FIG 5. PORTION OF INFLORESCENCE OF ACALYPHA HISPIDA.

Acalypha—*continued.*

regions, a few being extra-tropical American. Leaves alternate, often ovate, more or less toothed, three- to five-nerved or penniveined. To the species, &c., described on p. 7, Vol. I., the following should be added:

A. Chantrieri (Chantrier Frères'). A garden hybrid between *A. Hamiltoniana* and *A. macrophylla*. 1897.

A. Godseffiana (Godseff's). *l.* ovate-lanceolate, shining green, with creamy-white margins. New Guinea. An ornamental, dwarf, bushy shrub.

A. Hamiltoniana (Hamilton's). *l.* bright green, with prominently rounded, yellow teeth. 1895.

A. hispida (hispid).* *fl.* bright red, "resembling crimson plush," in drooping, tassel-like spikes, 12in. to 20in. long, sometimes 1in. in diameter, borne on axillary peduncles. *l.* spreading, 5in. to 5½in. long, 3in. to 3½in. broad, ovate, acute or shortly acuminate, rounded at base and emarginate at the insertion of the pubescent petiole, which is 2in. to 2½in. long; upper surface bright green and sparsely hairy; lower surface paler. *h.* 10ft. to 15ft. New Guinea, 1896. A beautiful species. See Fig. 5. SYN. *A. Sanderi.*

A. mortfontanensis (Mortefontaine). A garden hybrid between *A. Hamiltoniana* and *A. marginata*. 1897.

A. obovata (obovate). *l.* obovate, green with creamy edges when young, changing with age to olive-green with pink margins, and finally having a bronzy centre and broad rosy-crimson margins. Polynesia, 1884. An ornamental foliage plant.

A. Sanderi (Sander's). A synonym of *A. hispida.*

A. triumphans (triumphant). *l.* large, cordate, toothed, acute, variegated with deep crimson, green, and brown. Solomon Isles, 1888. A good foliage plant; probably a variety of *A. Wilkesiana.* (L. H. xxv., t. 55.)

A. eremorum, *A. illustrata*, and *A. Makoyana* are also occasionally seen in gardens

ACAMPE (from *akampes*, inflexible; in allusion to the very brittle texture of the flowers). ORD. *Orchideæ.* A genus embracing about nine species of stove, epiphytal Orchids, eight of which are natives of the East Indies and Southern China, while the other is found in South-east Africa; they are closely allied to *Saccolabium* (Hooker, in the "Flora of British India," includes them under that genus). Flowers much smaller than in *Vanda*, shortly pedicellate; sepals free, sub-equal, somewhat fleshy; petals similar but rather narrower; lip sessile at the base of the column, continuous, spreading, saccate or conico-spurred at base; column short and thick; peduncles lateral, rigid, short and simple, or elongated and panicled. Leaves distichous, coriaceous. Stem leafy, not pseudo-bulbous. For culture of the following species, *see* **Saccolabium.**

A. dentata (toothed). *fl.* whitish-yellow, blotched with brown, ¼in. to ½in. in diameter; panicle longer or shorter than the leaves, the branches distant and lax-flowered. *l.* 7in. to 9in. long, 1in. to 1½in. broad. Stem 1ft. to 2ft. long. India, 1872.

A. longifolia (long-leaved). *fl.* sweet-scented, inconspicuous, much like those of *A. multiflora*, corymbose; lip white. *l.* dark green, distichous, leathery, 1½ft. long, 2in. broad, obliquely rounded at apex. India.

A. madagascariensis (Madagascar). *fl.* small; sepals and petals whitish; lip rosy-purple. *l.* thick and leathery. Madagascar, 1891. Allied to *A. papillosa.*

A. multiflora (many-flowered). *fl.* yellow, with blood-coloured dots, small; lip ovate, somewhat acute; peduncle branched, erect, sub-corymbose, shorter than the leaves. *l.* lorate, obliquely emarginate at apex. China. SYN. *Vanda multiflora* (L. C. B, 38).

A. papillosa (papillose). *See* **Saccolabium papillosum.**

A. Wightiana (Wight's). *fl.* yellow, barred with crimson, not papillose, ¾in. to 1in. across; scape very stout; bracts very broadly ovate, acute. *l.* 4in. to 6in. long, ¾in. to 1in. broad. Stem 1ft. to 1½ft. long. India.

ACANTHEPHIPPIUM. *See* **Acanthophippium.**

ACANTHODIUM. Included under **Blepharis** (which *see*).

ACANTHOGLOSSUM. A synonym of **Cœlogyne** (which *see*).

ACANTHOLIMON. Prickly Thrift. SYN. *Armeriastrum.* ORD. *Plumbagineæ.* Eighty-four species have been described, but, according to Bentham and Hooker, some of them are mere varieties; they are natives of the Orient, extending from Greece and Syria to Western Thibet, and being most plentiful in Persia. These plants may also be increased by layering the shoots in late

Acantholimon—*continued.*

summer. To those described on p. 8, Vol. I., the following should be added:

A. androsaceum (Androsace-like). *fl.*, corolla of an intense purple, with an ample limb; spike very short, fasciculate-distichous, or sub-second, with three to seven spikelets; scape scarcely any or almost equalling the leaves. July. *l.* short. Branches short and densely spiny. *h.* 6in. Southern Europe, 1813. SYN. *Statice echinus* (S. F. G. 300).

A. melananthum (dark-flowered). *fl.* in a very short spike of six to nine spikelets; calyx limb bordered with dark violet or black. *l.*, lower ones very short, flat, triangular-lanceolate, mucronate; the rest spiny, short. Branches short. Persia.

ACANTHOMINTHA (from *akanthos*, a spine, in allusion to the spiny-toothed bracts, and *Mentha*, Mint, as the plant was formerly included under *Calamintha*). ORD. *Labiatæ.* A monotypic genus. The species is a small, glabrous, half-hardy annual, requiring ordinary cultivation.

A. ilicifolia (Holly-leaved). *fl.* three to eight in a whorl in all the upper axils; whorls subtended by opposite bracts, which are larger than the leaves and spiny-toothed; calyx tubular, bilabiate; corolla ¼in. long, the upper lip white, small, the lower one purple, with a yellow throat, four-lobed. July. *l.* petiolate, ½in. to 1in. long, rounded or ovate, with a cuneate base, coarsely and bluntly toothed. Branches ascending, 6in. to 8in. long. California, 1883. (B. M. 6750.)

ACANTHONEMA (from *akanthos*, a spine, and *nema*, a filament; in allusion to the filaments of the two inferior stamens being produced into a spine-like process just below the anther). ORD. *Gesneraceæ.* A monotypic genus. The species is a stove perennial, much resembling *Streptocarpus* in habit. It thrives in a compost of sandy loam and peat, the former predominating, and may be increased by seeds.

A. strigosum (strigose). *fl.* whitish, ¼in. to ¾in. long, with a blood-purple, five-lobed limb; panicles 1in. to 2in. high, sessile on the midrib at the base of the leaf. June to August. *l.* radical, solitary, 4in. to 9in. long, spreading on the ground, linear-oblong, cordate at base, shortly petiolate, recurved at apex, strigose with scattered hairs. Tropical Africa, 1862. (B. M. 5339.)

ACANTHOPANAX (from *akanthos*, a spine, and *Panax*; alluding to the spiny stems and Panax-like aspect of the plants). ORD. *Araliaceæ.* A genus embracing about eight species of stove or greenhouse, glabrous or tomentose shrubs (rarely trees ?), natives of Japan, China, and tropical Asia. Flowers polygamous or hermaphrodite; petals five, rarely four, valvate; stamens five, rarely four, the filaments filiform; pedicels continuous with the flowers; bracts small or wanting; umbellets paniculate or almost solitary. Leaves palmately cleft, digitate, or one-foliolate. Only two species call for mention here:

A. ricinifolium (Ricinus-leaved). The correct name of the plant described on p. 104, Vol. I., as *Aralia Maximowiczii.*

A. spinosum (spiny). The correct name of *Aralia pentaphylla.*

ACANTHOPHIPPIUM. About half-a-dozen species, natives of India, the Malayan Archipelago, &c., are included in this genus. To those described on p. 8, Vol. I., the following should be added:

A. Curtisii albidum (whitish). *fl.* creamy-white, with rose and purple dots on the inner surface, thick and fleshy; lateral sepals joining to form a large, pouch-like organ. 1898. (L., t. 619.)

A. eburneum (ivory-white). *fl.* white, nearly 2in. long; scape two-flowered. *l.* oblong-lanceolate, plicate, 8in. long, 2in. broad. Pseudo-bulbs purplish, angular, 2in. to 3in. long. Malaya (?), 1896. Allied to *A. Curtisii.*

A. Mantinianum (Mantin's). *fl.*, sepals yellow, slightly shaded with green, spotted and blotched with purple; petals resembling the sepals, but having the lower portion whiter; lip of a waxy white, the thickened part of the disk orange-yellow with ridges spotted and lined with purple. Philippines, 1896. A near ally of *A. bicolor*, from which it mainly differs in the colour of its flowers and its much more robust habit. (L. 1896, t. 536.)

A. striatum (striated). *fl.* white, streaked with red; lip with a single, median, crested ridge and thickened lateral curves, the side lobes very broad, falcate, obtuse, the mid-lobe scarlet, contracted, acute. Spring. Nepaul. Allied to *A. sylhetense*, but the flowers are much shorter.

ACANTHOPHŒNIX. Prickly Date Palm. Three or four species, all natives of the Mascarene Islands, are included in this genus. Flowers red or yellow, monœcious on the same spadix, borne under the leaves; spadix doubly branched, pendulous; spathes two, deciduous; bracts rather prominent, thick and rigid. Fruit black,

Acanthophœnix—*continued.*

sometimes scarcely longer than grains of wheat. Leaves terminal, equally pinnatisect, armed with more or less elongated spines. To the species described on p. 8, Vol. I., the following should be added:

A. grandis (large). This is described as "a handsome Palm, with finely-cut leaves and deep brown spines, native of Brazil" (in I. H. 1895, p. 185). According to the "Kew Bulletin," 1896, App. II., it is "also called *Calamus grandis*, and stated to be a native of Borneo" (I. H. 1895, p. 223). The genus is, however, according to Bentham and Hooker, as well as J. G. Baker, confined to the Mascarene Islands, as above stated.

A. Herbstii (Herbst's). A synonym of *A. crinita.*

A. rubra (red). *fl.* reddish-brown; spadix 2½ft. to 3½ft. long; peduncle 6in. to 10in. long, armed with straight spines; spathes 1½ft. to 2½ft. long. *l.* 6ft. to 12ft. long; leaflets slightly glaucous beneath; petioles glabrous, 2in. to 4in. long; sheaths 2½ft. to 4½ft. long, thickly covered with brownish-black spines. *h.* 60ft. SYN. *Calamus Verschaffeltii* (of gardens).

ACANTHOSTACHYS [not *Acanthostachyum*]. According to J. G. Baker, this genus embraces a couple of species, natives of Brazil. Sepals lanceolate-deltoid, acute, free to the top of the ovary; petals lingulate, scaled at base, rather longer than the calyx; stamens shorter than the petals. *A. strobilacea* is the only species known in gardens.

ACANTHOSTIGMA PARASITICUM. *See* **Silver Leaf Disease.**

ACANTHUS. Including *Dilivaria.* About fourteen species, inhabiting tropical and sub-tropical regions, are included in this genus. To those described on pp. 8-9, Vol. I., the following should be added:

A. Caroli-Alexandri (Charles Alexander's). *fl.* white, often suffused rose-colour, in a dense spike. Summer. *l.* few, radical, in a lax rosette, lanceolate, pinnatifid, spiny-toothed, 16in. long, 3in. to 4in. broad. Stem 9in. to 18in. high, with two to four similar leaves. Greece, 1837. (R. G. 1886, pp. 626-635, f. 73-75.)

ACARIDA. *See* **Ticks.**

ACCLIMATISATION. Popularly this is the inuring of plants, &c., to a climate different from that of which they are native, which is, however, fallacious. No tender plant has yet by any process, gradual or otherwise, been rendered hardy. Those who put forth the theory adduce as a case in point the common Larch. That this tree and many others were originally grown in this country as greenhouse subjects there cannot be any doubt; but this was due to a lack of knowledge.

With plants that reproduce themselves by seed, it is possible, by annually selecting the hardiest and most vigorous individuals, and using these again as seed-parents, to produce a hardier race. And conversely it is possible, by choosing as seed-parents individuals which stand the heat best, to develop, after a few generations, tropical races of cool-country vegetables and flowers: such selection is constantly going on in India, &c., amongst vegetables raised, in the first place, from English seeds.

ACCRESCENT. Increasing in size after flowering.

ACER. The species of this genus number upwards of fifty, and are found in Europe, North America, North Asia, Java, and the Himalayas. Flowers racemose or corymbose, axillary and terminal, generally polygamo-dicœcious. Leaves opposite, usually palmately or sub-pedately three- to seven-lobed or parted, rarely entire. To the species and varieties described on pp. 9-11, Vol. I., the following should be added. **Negundo** (which *see*) is now included hereunder.

A. argutum (sharp). *l.* palmately lobed, borne on long petioles. Japan. A very elegant species, of medium height; it is as yet very uncommon in English establishments.

A. campestre postelense (Postel). A yellow-leaved form. 1896.

A. caucasicum (Caucasian). A synonym of *A. hyrcanum.*

A. cissifolium (Cissus-leaved). The correct name of *Negundo cissifolium.*

A. coccineum (scarlet). A synonym of *A. rubrum.*

A. colchicum (Colchican). A synonym of *A. pictum rubrum.*

A. c. tricolor (three-coloured). A synonym of *A. pictum tricolor.*

A. cratægifolium (Hawthorn-leaved). *l.* small, deep green, closely resembling those of Hawthorn. Japan. A slender tree.

Acer—*continued.*

The form *Veitchi* is very attractive, having variegated leaves it is very uncommon and quite hardy.

A. dasycarpum pulverulentum (powdered). In this form the leaves are spotted with white and the tips of the young shoots tinted red. 1889.

A. diabolicum (diabolical). *fl.* greenish-yellow, large, disposed in numerous short racemes. Spring. *l.* large, Plane-like. Branches stout. Japan. A free-growing tree. SYN. *A. pulchrum.*

A. Duretti aureo-marginatum (Durett's gold-margined). *l.* margined and dotted yellow. 1896.

A. Ginnala. There are several forms of this variety of *A. tataricum*, including *angustilobum* (leaves narrow-lobed) and *pulverulentum* (powdery).

A. Heldreichii (Heldreich's). *fl.* in small, terminal panicles, which are shorter than the leaves. *l.* small, palmately five-lobed; lobes obtusely dentate, acute, the middle one cuneately tapering to its base. Greece. (G. C. 1861, xv., p. 141; R. G. 1185.)

A. hyrcanum (Hyrcanian). *fl.* in sub-sessile, nodding corymbs. *l.* sub-orbicular, cordately five-cleft, rich green, shaded with yellow, later brownish-tomentose on the under-side, very pleasing in autumn when turning to a reddish-brown; lobes obovate, incised or toothed. Caucasus. A compact species, of rather slow growth. SYN. *A. caucasicum.*

A. insigne (remarkable).* *fl.* green, ¼in. in diameter; panicles pyramidal, terminal, 3in. to 4in. long, appearing with the leaves. May. *l.* 5in. to 6in. in diameter, rounded-reniform, palmately divided to the middle into five to seven oblong, acute, coarsely and obtusely serrated lobes, glabrous above, more or less tomentose beneath. Persia. The latest of all the Maples to come into leaf. (B. M. 6697.) SYN. *A. velutinum.*

A. integrum (entire). A synonym of *A. palmatum linearilobum.*

A. Juhlkei variegata (Juhlke's variegated). *l.* when young having about half their area creamy-coloured, but the variegation very irregular. 1898.

A. lætum (pleasing). This species is closely related to *A. Lobelii*, but is principally distinguished in having leaves more cordate at the base, more delicate, more glaucous, and with the lobes more pointed. Orient.

A. marmoratum (marbled). A variety of *A. pictum.*

A. Miyabei (Miyabe's). A fine, ornamental species, nearly related to the Norway Maple, *A. platanoides.* Japan, 1894. (G. and F., 1893, 143.)

A. neapolitanum (Neapolitan). A variety of *A. opulifolium.*

A. Negundo. The correct name of *Negundo fraxinifolium.*

A. N. elegans (elegant). *l.* pale green, irregularly bordered and splashed with yellow, changing to creamy-white with age. A fine, decorative, free-growing tree.

A. N. foliis-marginatis-aureis (leaves golden-margined). *l.* bordered with golden-yellow. 1889. This variety is as constant as the silver-variegated form, and of more vigorous growth.

A. N. Guichardi (Guichard's). *l.* all yellow, resembling those of the golden Elder. 1889. A fairly vigorous form.

Among other new varieties of this popular species may be mentioned the following: *boreale* (said to have been introduced from Canada, and to ripen seeds in the colder parts of Europe where the typical plant would be killed by frost); *densiflorum* (dense-flowered); *falcatum* (sickle-shaped); *Koehneanum* (Koehne's); *odessanum* (leaves of a deeper golden, and retaining that colour longer, than in the type); *pendulum* (a weeping form); *rectangulum* (right-angled).

A. nigrum (black). A form of *A. saccharinum.*

A. nikoense (Niko). The correct name of *Negundo nikoense.*

A. opulifolium neapolitanum (Neapolitan). This nearly resembles the variety *obtusatum*, but differs by its undulated leaves with more pointed lobes and by the larger fruits with longer, spreading wings.

A. ornatum (ornate). A form of *A. palmatum.*

A. palmatum Aokii (Aoki's). *l.* creamy-white and pink, finely divided. 1892. (R. G. 1363.)

A. p. aureum (golden). A handsome form, with rich yellow foliage.

A. p. dissectum roseo-pictum (rose-painted). A garden sub-variety. 1887.

A. p. linearilobum (linear-lobed).* *l.* deep olive-green, much divided, the lobes almost linear. 1896. A handsome Japanese Maple. See Fig. 6. SYN. *A. integrum.*

A. p. ornatum (ornate). *l.* digitate, borne on slender petioles, their divisions attenuated and deeply cut, with long, slender, toothed segments. Branches numerous, feathery. Japan, 1867. A beautiful, slender tree. (R. H. 1867, p. 391.)

A. p. septemlobum elegans (elegant). *l.* changing from pale green through pink and crimson to dull red, beautifully lobed. The form *laciniatum* has soft green leaves touched with rose-colour.

A. pictum marmoratum (marbled). *l.* palmate, acutely lobed, marbled with yellowish-green on a deeper green ground, freely produced on the new growth. Habit bushy. 1894.

A. p. tricolor (three-coloured). *l.*, young ones of a bright violaceous-red, irregularly shading off here and there into all tints of dark red or crimson to creamy-white. 1880. Garden variety. SYN. *A. colchicum tricolor.*

Acer—*continued.*

A. platanoides compactum (compact). An ornamental variety, producing a compact, round head. 1886.

A. p. globosa (globular). A neat, round-headed form, rather slow in growth.

A. p. integrilobum (entire lobed). This only differs from the type in having the lobes of the leaf entire. (R. G. 1837, p. 431, f. 107-8.)

A. p. multicolor (many-coloured). *l.* red, large, speckled and blotched with yellowish-white later. 1896.

A. p. Reitenbachii (Reitenbach's). *l.* large, changing in the autumn to a deep crimson-red, varying to yellow and brown.

A. p. rubrum (red). A variety with leaves distinctly reddish-brown.

A. p. undulatum (wavy). *l.* bullate, with very wavy, crisped margins. A curious and interesting variety.

Among other varieties of the Norway Maple the following may be mentioned: *columnare, dilaceratum, euchlorum, integrifolium, nanum* (SYN. *pygmæum* of gardens), and *quadricolor.*

A. polymorphum (many-formed). A synonym of *A. palmatum.*

FIG. 6. ACER PALMATUM LINEARILOBUM.

A. Pseudo-platanus atropurpureum (dark purple).* A very fine variety, with dark purple leaves; worthy of extensive cultivation.

A. P.-p. elegantissimum variegatum (very elegant, variegated). *l.* in spring suffused with rose-pink on a cream ground, and in some cases irregularly splashed with green. A vigorous and showy sport from *A. P.-p. Leopoldi.*

A. P.-p. flavo-marginatum (yellow-margined). *l.* pale green, mottled and edged with white.

A. P.-p. Leopoldi (Leopold's). *l.* marbled with purple, yellow, and green; petioles red. A very pretty, Belgian variety.

A. P.-p. Webbianum (Webb's). Similar in colour of leaves to *flavo-marginatum*, but of more vigorous growth.

A. pulchrum (pretty). A synonym of *A. diabolicum.*

A. pygmæum (dwarf). A garden name for a dwarf form of *A. platanoides integrilobum.*

A. rubrum Drummondi (Drummond's). *l.* streaked with red on the upper surface, glaucous beneath. 1892. (R. G. 1374.)

A. septemlobum (seven-lobed). A form of *A. palmatum.*

A. Trautvetteri (Trautvetter's). A synonym of *A. Van Volxemi.*

A. Van Volxemi erythrocarpum (red-fruited). A variety with red fruit. Caucasus, 1892.

A. velutinum (velvety). A synonym of *A. insigne.*

A. Wieri laciniatum (Wier's, cut). A weeping variety, having long, slender shoots clothed with delicately-cut foliage; it is admirably adapted for the outskirts of the lawn.

INSECTS AND DISEASES. Several of the commoner species of Maples used for the decoration of large gardens and parks are frequently almost defoliated early in the season. This is especially the case with the Norway Maple (*A. platanoides*), the Common Maple and its varieties, and less frequently, perhaps, with the Sycamore. Such defoliation usually takes place between August and September, and is very noticeable some years in our London parks.

Acer—*continued.*

It is due to a distinct and well-characterised fungus, *Rhytisma acerinum.* Popularly it is sometimes called Maple Blotch, on account of the roundish yellow patches found upon the foliage in late summer. These towards autumn take on a black colour, and the leaves are shed. In such cases spraying is out of the question, and preventive measures must alone be relied upon for lessening the attack another season. This is best done by collecting and burning the leaves, which otherwise would be the means of conveying the disease to the trees in the spring.

Another fungus frequently found upon Maples (*Acer*), as well as upon other trees used ornamentally in parks and large gardens, is *Nectria cinnabarina*, a near relative of that pest of Apple Orchards mainly responsible for the condition known as Canker. These are popularly known as Wound Fungi, on account of their only attacking a tree which has previously been injured either by atmospheric influences, or by careless use of tools at planting time, &c. *N. cinnabarina* is quite unable to attack a tree with absolutely sound bark; but once a wound has been made the fungus finds an entrance, and the wood is immediately involved, as the mycelium spreads rapidly, working in an upward direction. Naturally, the sap-flow is considerably interfered with, and that portion of the tree is unable to receive any nourishment, the wood assumes a blackened appearance, and the invaded branches die away. To an unpractised eye the causes may not at first be evident, though later they should be, when the very beautiful orange-red stromata are produced upon the bark in the vicinity of the wound. These are followed by the warted, button-like reddish growths, and the tree goes from bad to worse. As this is one of the fungi requiring not even a glass to see its beautiful stromata, it should be readily recognised, and preventive measures adopted. The importance of at once dealing with bark-wounds caused by frost, hail, as well as by implements, will be apparent. The best application is a smear of tar. When, however, branches die, and the presence of the fungus is noted in their vicinity, such dead portions should be cut away directly they are seen, and burned. Fallen branches and twigs should be also burned. This fungus is parasitic as well as saphrophytic.

One of the chief insect depredators to Maple foliage is a species of Sawfly, *Phyllotoma aceris*, whose larvæ are leaf-miners. Their presence may be indicated by an irregular blotch, especially if the leaf or leaves be carefully examined. The larvæ are usually feeding at midsummer, or a little earlier. Little can be done at that time, though later, when in the pupa-state, the cocoons may be collected from the tree-trunk and burned. These Sawflies seem most partial to *Acer Pseudo-platanus.*

Other insects in the form of the ubiquitous Vapourer Moth Caterpillar (*Orgyia antiqua*) also attack the trees, especially in towns; and where a good force of water can be applied, as from a stand-pipe or powerful engine, a good washing several times during a very dry summer would be useful in dislodging such pests.

ACERANTHUS (from *Acer*, the Maple, and *anthos*, a flower; the flowers resemble those of the Maple). ORD. *Berberideæ.* A monotypic genus. The species, *A. diphyllus*, is a hardy herbaceous perennial, with a creeping rhizome, also known as *Epimedium diphyllum* (under which name it is described in Vol. I.). Sepals seven or eight, resembling the petals, the outer ones rather smaller; petals flat; stamens four, free. Stem one-leaved, racemose at apex.

ACERATIUM. Bentham and Hooker include this genus under **Elæocarpus** (which *see*).

ACERINEÆ. The *Acerineæ* are now regarded as a sub-order of the Natural Order *Sapindaceæ.* It embraces the well-known genera *Acer* and *Negundo* (the latter now included under *Acer.* Flowers regular. Leaves always opposite, simple or pinnately three- to five-foliolate.

ACHANIA. A synonym of **Malvaviscus** (which *see*).

ACHERONTIA ATROPOS. *See* **Death's-Head Moth.**

ACHETA. This was the old generic name for the Crickets, of which there are four representatives in this country, and three of them injurious to field and garden produce. The more modern names for the Crickets are *Gryllus domesticus* (House Cricket), *Gryllus campestris* (Field Cricket), *Nemobius sylvestris* (Small Field Cricket), and *Gryllotalpa vulgaris* (Mole Cricket). *See* **Crickets** and **Mole Cricket.**

ACHILLEA. Yarrow. Upwards of 100 species have been described by botanists (but according to the authors of the "Genera Plantarum," the number may be considerably reduced): they inhabit Europe and Western Asia, *A. Ptarmica* (Sneezewort) and *A. Millefolium* being indigenous in Britain. Leaves alternate.

FIG. 7 ACHILLEA (THE PEARL).

The Achilleas are all sun-lovers, and though, as stated in Vol. I., many are coarse-growing, yet there are a few which are really choice, hardy perennials, decorative in the borders, and extremely useful for furnishing cut-flower material. The best for this are *A. mongolica* and the double-flowered forms of *A. Ptarmica*, like The Pearl (see Fig. 7) and Snowball. To the species described on pp. 11-12, Vol. I., the following should be added:

A. ageratifolia (Ageratum-leaved). The correct name of *Anthemis Aizoon*; it is also called *A. ageratoides* in gardens.

A. micrantha (small-flowered). *fl-heads* yellowish, in a compound, fastigiate corymb; ray florets five, obtusely three-toothed at apex. Summer. *l.* pinnatisect, with pinnatipartite segments; lobes linear, entire, acute. Stems erect. Cappadocia, &c. A decorative, hairy perennial.

A. rupestris (rock-loving).* *fl.-heads* white, greenish towards the centre, pedicellate, ½in. to ¾in. broad; corymbs 1in. to 1½in. in diameter. May. *l.* on the shoots rosulate, ½in. to ¾in. long, linear-spathulate, entire; cauline ones similar, scattered, spreading. Rootstock tufted. Southern Italy, 1886. (B. M. 6905.)

ACHIMENES. SYNS. *Cyrilla* (of L'Héritier), *Trevirana*. Including *Dolichoderia*, *Eucodonia*, *Kœrnickia*, *Locheria*, *Mandirola*. About a score species, all tropical American (from Brazil to Mexico), are included in this genus. To the species and varieties described on pp. 12-14. Vol. I., the following should be added:

A. amabilis (lovely). A synonym of *Nægelia multiflora*.

A. argyrostigma (silvery-spotted). A synonym of *Kœllikeria argyrostigma*.

A. candida. The correct name is *Dicyrta candida*.

A. cupreata. The correct name is *Episcia cupreata*.

A. gloxiniæflora. The correct name is *Gloxinia glabrata*.

A. Jaureguia (Jaureguia). A variety or synonym of *A. longiflora*.

A. lanata (woolly). *fl.*, corolla pinkish-lilac, swelling from the base, the lobes purple-veined and denticulate, the throat white, with orange dots; peduncles axillary, one-flowered, nearly four times the length of the petioles. October. *l.* broadly ovate, obtuse at both ends, crenulate, roughly veined on the upper surface. Stem (and foliage) more or less whitish-hairy. *h.* 6in. Mexico, 1856. SYN. *Scheeria lanata* (B. M. 4963).

A. ocellata. The correct name is *Isoloma ocellatum*.

Achimenes—*continued.*

A. picta (painted). The correct name is *Isoloma bogotense*.

A. Scheerii (Scheer's). *fl.* purplish or bluish; calyx hairy; corolla funnel-shaped, pubescent-hairy outside, puberulous within. August. *l.* opposite, petiolate, ovate, acuminate, serrated, greenish-purple beneath. Stems erect, hairy. *h.* 9in. Mexico, 1850. SYN. *Scheeria mexicana* (B. M. 4743).

A. tubiflora (tubular-flowered).* *fl.* pure white; corolla tube 4in. long, a little enlarged and curved upwards, with a broad gibbosity at base, the limb 1½in. broad, equally five-lobed; pedicels 2in. long; panicle several-flowered. Summer. *l.* opposite, oblong, acuminate, reticulated, downy, obscurely crenate; petioles short and thick. Buenos Ayres. See Fig. 8. SYNS. *Dolichoderia tubiflora*, *Gloxinia tubiflora* (B. M. 3971; B. R. 1845, 3).

VARIETIES. In addition to those given in Vol. I. the following may be named:

ARCTURUS, deep red; BRILLIANT, scarlet; CELESTIAL, white, violet-tinged, large flower; CHELSONI, dark blue, very free; COQUETTE, violet-purple, beautifully ringed at throat; EDMUND BOISSIER, white, tinged lilac; ESTELLE, violet, white centre; LADY LYTTELTON, violet-purple, with yellow throat; SIR TREHERNE THOMAS, rose-purple, very free; VIOLETTA, violet-purple, darkly veined at throat.

FIG 8. FLOWERING BRANCH OF ACHIMENES TUBIFLORA.

ACHIMENES (of Vahl). A synonym of **Artanema** (which *see*).

ACHRAS (from *Achras*, a kind of wild Pear). SYN. *Sapota*. ORD. *Sapotaceæ*. A monotypic genus. The species is the plant described in Vol. III. as *Sapota Achras*. *See also* **Sideroxylon.**

ACHROANTHES. A synonym of **Microstylis** (which *see*).

ACIDANTHERA (from *akis*, a cusp, and *anthera*, an anther; the anthers are cuspidate). SYN. *Sphærospora*. ORD. *Irideæ*. A genus consisting of seventeen species of stove and greenhouse perennials, natives of tropical and South Africa. Flowers few, loosely spicate; perianth-tube usually long, cylindrical, slightly dilated upwards, the segments sub-equal; stamens unilateral, inserted at or a little below the throat; spathe-valves like those of *Gladiolus*, green, long, lanceolate. Leaves linear. Rootstock a tunicated corm.

A. bicolor is one of the three species at present introduced which is upon the market. Although not quite hardy, still in favoured soils and situations in the south of England its culture may be attempted, treating it

Acidanthera—*continued.*

much on the lines of Ixias, which it approaches. It makes a very good pot-plant.

A. æquinoctialis (Equinoctial).* *fl.* about six in a distichous spike; perianth-tube 5in. to 6in. long, the limb 2in. in diameter, the segments white, with an acute, purple spot at base; outer spathe-valves 3in. to 4in. long. November. *l.* many, superposed, ensiform, 1ft. to 1½ft. long, strongly ribbed. Stem stiffly erect, 3ft. to 4ft. high. Corm large, depressed-globose. Sierra Leone, 1893. This requires a warm house. (B. M. 7393.)

A. bicolor (two-coloured). *fl.* few, in a very lax spike; perianth white, with a slender tube 4in. to 5in. long, the segments acute, 1¼in. to 1½in. long, the three lower ones conspicuously spotted with purple at the throat. Stem simple. Corm globose, ½in. in diameter. Abyssinia, 1896. Hardy. (G. C. 1896, xx., p. 393.)

A. capensis (Cape). The correct name of *Tritonia capensis*.

ACINETA. Syn. *Neippergia*. This genus comprises about eight species, all natives of tropical America. Though classed as cold-growing Orchids, the Acinetas thrive more satisfactorily in an intermediate temperature, especially during the dull winter months of the year. They require a liberal amount of moisture at the root during the growing season, but care must be taken to avoid stagnation, which causes the potting compost to decay, whereby the roots and the general health of the plant are affected, often leading to destruction. Syringing and damping overhead must also be done with discretion, and should only be attempted in bright, dry weather. It should always be done sufficiently early in the day to enable the foliage to become dry again before the evening, when a fall of temperature sets in. Excessive accumulation of moisture in the hearts of the young growths must also be strictly guarded against, or they will quickly rot off. Where accumulated moisture is observed, the plant should be held upside down, and by gently tapping the growth affected the moisture will be dispersed. These precautions are especially necessary when the plants are grown under cool conditions, or suspended in a house where the sash-bars are not properly grooved to carry off the condensed moisture. Propagation is effected by division of the pseudo bulbs, preferably when the new roots are emitted from the base of the newly made growths. Purchase of Imported plants is, however, by far the most satisfactory way of increasing the stock. To the species described on p. 14, Vol. I., the following should be added:

A. Hrubyana (Hruby's). *fl.* ivory-white, disposed in loose racemes; lip marked with a few purple spots, and having narrow, erect side lobes. Colombia, 1882. A fine and distinct species.

A. Humboldtii fulva (fulvous). *fl.* tawny-yellow, dotted all over with purplish-brown; lip of a brighter yellow, spotted with dark purple. A handsome variety. (B. M. 4156.)

A. H. straminea (straw-coloured). *fl.* pale straw-yellow, with very few spots. Colombia.

A. superba (superb). A synonym of *A. Humboldtii*.

A. Wrightii (Wright's). A synonym of *Lacæna spectabilis*.

ACINOS. Included under **Calamintha** (which *see*).

ACIOTIS. Syn. *Spennera*. About twenty-six species of this genus, natives of the West Indies and tropical America, have been described.

ACIPHYLLA. Syn. *Gingidium* (of F. Mueller). This genus includes about a score of species, natives of New Zealand and Australia. To those described on p. 14, Vol. I. (both of which are called "Wild Spaniard" by settlers), the following should be added:

A. Lyalli (Lyall's). *fl.* white; inflorescence long and contracted; female umbels almost concealed in the tumid sheaths of the bracts; male umbels on spreading, branched peduncles. *l.* simply pinnate or trifoliolate; leaflets rigid, pungent, 4in. to 6in. long, ¼in. broad. New Zealand, 1889.

ACIS. This genus is included by J. G. Baker under **Leucoium** (which *see*), the specific names remaining unchanged. *A. grandiflorus* is, however, regarded as merely a variety of *A.* (*Leucoium*) *trichophyllus*.

A. roseus longifolius (long-leaved). This differs from the type in its larger flowers, longer leaves, and more floriferous habit. Corsica, 1886.

ACISANTHERA. Syn. *Uranthera*. According to the "Genera Plantarum," this genus embraces about fourteen species of glabrous, pilose, or slightly hispid, stove herbs (often annuals) or sub-shrubs, inhabiting the West Indies and tropical South America. Flowers purple and pink, terminal and axillary, shortly paniculate; calyx with a hemispherical or campanulate tube and four or five acuminate lobes as long as the tube; petals four or five, obovate or orbicular; stamens eight to ten, unequal. Leaves almost sessile, entire or serrated. *A. quadrata* is probably the only species in cultivation.

ACMELLA. Included under **Spilanthes** (which *see*).

ACMENA. Bentham and Hooker include this genus under **Eugenia**.

A. floribunda. Synonymous with the plant correctly described in Vol. I. as **Eugenia Smithii**. (B. M. 5480.)

ACOKANTHERA. This is the correct name of the genus described on p. 63, Vol. IV., as **Toxicophlæa** (which *see*).

ACONITUM. According to Bentham and Hooker, the number of distinct species is only about eighteen, many of the plants described on pp. 15-17, Vol. I., being mere varieties. They are chiefly mountain plants, spread over the greater part of Europe and Central Asia, very few species being found in North America. *A. Napellus* is a British species.

Though Aconites will grow fairly well almost anywhere, they are best accommodated in a deep, fairly rich soil, and in partial shade. Their spikes of flowers look remarkably well in a mixed border of good width. They are best divided in autumn. The following are the only additions calling for mention:

Sect. I.—Roots Tuberous.

A. californicum (Californian). A garden synonym of *A. Fischeri*.

A. decorum (neat). A garden synonym of *A. Cammarum*

A. dissectum (dissected). This plant has much in common with *A. Napellus*, but it is more hairy. The principal difference is exhibited in the narrower helmet of the flowers. Himalayas, 1885. (R. G. 1886, p. 226, f. 16.)

A. Fischeri (Fischer's). *fl.* pale blue, large, puberulous, many in a straight, erect raceme. October. *l.*, cauline ones petiolate, tripartite; segments cuneate, trifid, incised-lobed. Europe, North America, &c., 1886. Plant erect, robust. (B. M. 7130.) Syn. *A. californicum* (of gardens).

A. hamatum (hooked). A synonym of *A. variegatum*.

A. hebegynum, of gardens. A synonym of *A. variegatum bicolor*.

A. longebracteatum (long-bracted). A fine garden form of *A. Napellus*.

A. Sterckianum (Sterck's). A synonym of *A. intermedium*.

Sect. II.—Roots Fibrous.

A. Fortunei (Fortune's). The correct name of *A chinense* (B. M. 3852; P. M. B. v., t. 3). Syn. *A. sinense*, of Lindley (P. F. G. i., p. 187, f. 116.

A. sinense (Chinese), of Lindley. A synonym of *A. Fortunei*.

A. grandiflorum (large-flowered). A synonym of *A. vulparia*.

ACRATHERUM. A synonym of **Arundinella** (which *see*).

ACRIDOCARPUS. Syn. *Anomalopteris*. This genus embraces about a dozen species of stove or greenhouse trees and shrubs, natives of tropical and South Africa, Madagascar, and Arabia. Flowers yellow, racemose or rarely corymbose; calyx deeply five-cleft; petals unequal, clawed, almost entire; stamens ten, all perfect; racemes or corymbs terminal and lateral, often paniculate. Leaves alternate, rarely opposite, entire, often glandular beneath, without stipules.

ACROCHÆNE (probably from *akros*, top, and *chaino*, to gape; reason not obvious). Ord. *Orchideæ*. A small genus (two species) of stove, epiphytal Orchids, natives of tropical Asia. Sepals spreading, sub-equal; petals small, lacerated; lip erect, shorter than the sepals, with a short claw; scape lateral, erect; raceme long, lax. *A. Rimanni* is said to be grown in this country; it requires

Acrochæne—*continued.*

similar culture to **Cœlogyne** (which *see*), and should be grown in an intermediate temperature.

A. Rimanni (Rimann's). *fl.* nearly equal to those of *Dendrobium Kingianum*; sepals lilac-purple, the lateral ones connate; petals lilac-purple, short, oblong, denticulate; lip very dark purple, having each lateral lobe semicircular and denticulate. 1882.

ACROCLINIUM. Bentham and Hooker include this genus under **Helipterum** (which *see*), the correct name of *A. roseum* being *H. roseum*.

A. roseum album flore-pleno (double-flowered). A pretty, double-flowered variety.

ACRONYCHIA. Syns. *Cyminosma*, *Gela*, *Huonia*, *Jambolifera*. About fifteen species are referred to this genus; they are stove or greenhouse trees, natives of tropical Asia, Australia, and Oceania. Corymbs pedunculate, axillary and termimal. Leaves opposite or alternate, with one to (rarely) three leaflets; leaflets ample, entire, pellucid-dotted. The plant formerly known as *A. Cunninghami* now forms the monotypic genus **Medicosma** (which *see*). To the information given on p. 18, Vol. I., the following should be added:

A. lævis (smooth). *fl.* white, in di- or trichotomous cymes, usually shortly pedunculate. July. *l.* irregularly opposite or alternate, consisting of a single leaflet, obovate-oblong to oblong-elliptical, obtuse, 1½in. to 4in. long. Australia, 1824. Syn. *Cyminosma oblongifolium* (B. M. 3222).

ACRONYCTA PSI. *See* **Grey Dagger Moth,** and also **Pear Insects.**

ACROPHYLLUM. Syn. *Calycomis* (of Don). Tribe *Cunonieæ* of Ord. *Saxifrageæ*. This genus is monotypic, the species being *A. venosum* (B. ii., t. 95), described in B. M. 4050 as *A. verticillatum*.

ACROSSANTHES. A synonym of **Vismia** (which *see*).

Fig. 9. Acrostichum aureum.

ACROSTICHUM. Including *Hymenolepis*, *Jenkinsia*, *Leptochilus*, *Macroplethus*, *Microstaphyla*, *Photinopteris*, *Pœcilipteris*, and *Teratophyllum*. The species number upwards of 180. The genus is exceedingly rich in plants of decorative value. Some of the strongest-growing kinds are particularly adapted for covering trunks of Tree-Ferns, walls, columns, &c., which they ascend by means of the extension of their rhizomes. In such situations they produce a very striking effect, hiding as they do unsightly supports or other equally objectionable objects. As before stated, in the work proper, the species with long fronds are most valuable for growing in hanging-baskets; while for most of the species, with entire or simple fronds, pot-culture must necessarily be resorted to. In whatever way they are grown, Acrostichums

Acrostichum—*continued.*

require a liberal supply of water at the roots; consequently, the compost used must be of a very porous nature. A mixture of two parts fibrous peat, one part chopped sphagnum, and one part coarse silver sand, will be found to suit nearly all known species.

One of the finest species in the large genus is *A.* (*Chrysodium*) *aureum* (see Fig. 9), which requires the temperature of a warm house, and to be treated as an aquatic. It should be potted in equal parts fibrous peat and loam, and, provided there is abundance of heat in the house, it will form a very striking object if the lower part of the pot can be kept in water.

Fig. 10. Acrostichum crinitum.

The Elephant's-Ear Fern (*A.* (*Hymenodium*) *crinitum*), has a very appropriate popular name, as the fronds (Fig. 10) have more than a fanciful resemblance to the ears of the elephant. A mixture, composed of two parts peat and one part chopped and partly-decayed sphagnum, is what this species prefers; but in such a compost care must be taken that it does not get treated too liberally with water at the roots, as in that case it is not unusual to find the fleshy fronds covered with circular marks, having all the appearance and transparency of oily spots, which gradually extend over their surface, and completely destroy it. This peculiar condition we have not found in any other species except Platyceriums, all of which are subject to it to the same extent; it is invariably due to stagnation at the roots. The most efficacious treatment consists in entirely removing the soil from the roots, by washing them, and re-potting in a smaller pot. After this operation, very little water should be allowed, and even when in good health, unless growing in great heat, *A. crinitum* should be watered only when showing signs of flagging.

Two or three other representatives of this interesting genus require special treatment if the best results are to be obtained. *A. peltatum* is one. Unless kept in a place naturally moist, this elegant little Fern, which does not like having its roots disturbed more than is necessary, and which, furthermore, requires a liberal supply of water *all the year round*, is considered a somewhat shy

Acrostichum—*continued.*

grower. When, however, in a place in which a permanently moist atmosphere may be depended upon, it grows freely in a mixture, in about equal proportions, of partly-decayed leaf-mould, fibrous peat, and silver sand. Also impatient of root-disturbance is the beautiful *A. scolopendrifolium*, which thrives best when pot-bound, providing the watering is carefully done.

FIG. 11. ACROSTICHUM AUBERTII.

A. scandens, though usually regarded as a stove fern, grows very well in the intermediate house, where the winter temperature occasionally falls below 50deg. Fahr. It prefers a compost of an open nature made of fibrous loam, fibrous peat, partly-decayed leaf-mould, and silver sand, in equal parts, with abundance of water at the roots all the year round. To the species, &c., described on pp. 18-20, Vol. I., the following should be added. Except where otherwise indicated, stove treatment is required.

FIG. 12. ACROSTICHUM CŒNOPTERIS.

Acrostichum—*continued.*

A. Aubertii (Aubert's). *rhiz.* woody, short-creeping, prostrate, densely scaly. *barren fronds* 1ft or more in length, borne on stems 4in. to 6in. long, clothed with squarrose, linear, brown scales. *fertile fronds* 2in. to 3in. long, suddenly narrowed at base, borne on stems 6in. to 9in. long. Bourbon, Natal, &c. A distinct species, resembling *A. viscosum*. See Fig. 11.

A. Burchellii (Burchell's). *rhiz.* short, woody, with small, dark brown scales. *sti.* 8in. to 12in. long, erect, nearly naked. *barren fronds* 1ft. to 2ft. long, ¾in. to 1¼in. broad, the point very acute, the lower part very gradually narrowed, naked and glossy on both sides. *fertile fronds* much smaller. Brazil.

A. buxifolium (Box-leaved). A variety of *A. sorbifolium*.

A. Cœnopteris (Cœnopteris). *rhiz.* woody, densely covered with rusty scales, trailing, as thick as a finger. *sti.* straw-coloured, 6in. to 12in. long, scaly below. *barren fronds* 2ft. to 3ft. long, about 1in. broad, simply pinnate; pinnæ coriaceous, 4in. to 8in. long, 1½in. broad, entire, toothed. *fertile fronds* narrower, bipinnate. Mexico. A strong-growing, stove or greenhouse species, better adapted for growing on partly-decayed branches of trees than for pot culture. See Fig. 12. SYN. *Soromanes serratifolium*.

A. conforme alatum (winged). This "has a more distinct haft to the frond" (Baker). There are several other varieties.

A. contaminans (contaminating). A form of *A. virens*.

FIG. 13. ACROSTICHUM DRYNARIOIDES.

A. costatum (ribbed). A form of *A. virens*.

A. crassinerve (thick-nerved). A variety of *A. latifolium*.

A. crispatulum (slightly curled). A form of *A. virens*.

A. cultratum (knife-shaped). *rhiz.* wide-creeping or long-trailing. *barren fronds* 6ft long, bright green; pinnæ ligulate, 6in. to 8in. long, 1½in. broad, cut down to a narrow wing into undivided, close, blunt lobes. *fertile fronds* having pinnæ more distant and only ¼in. broad. Solomon Islands. One of the most gigantic species in cultivation. SYN. *Chrysodium cultratum*.

A. decoratum (decorative). *cau.* stout, furnished with bright brown scales ¾in. long. *barren fronds* 1ft. or more in length, 3in. to 4in. broad, coriaceous, bright green, acute, rounded at base, the edges densely fringed with squarrose, brown scales. *fertile fronds* nearly as large as the barren ones. West Indies, &c. A handsome species.

A. drynarioides (Drynaria-like). *fronds* several feet long, 1ft. or more in breadth, stalkless; upper part furnished with Lomaria-like pinnæ quite 1ft. long, and which, although adnate to the rachis, break away from it readily. Penang and the Solomon Islands. A peculiar species. See Fig. 13. SYN. *Photinopteris drynarioides*.

A. Harlandii (Harland's). *sti.* firm, glossy, 1in. to 1½in. long, chestnut-brown, scaly at base. *barren fronds* usually entire, but sometimes having a spathulate terminal pinna 1ft. long and 3in.

Acrostichum—*continued.*

broad and one or two similar but smaller ones on each side, usually connected at the base, all coriaceous. *fertile fronds* similar, but with much smaller pinnæ. Hong-Kong and Formosa. A handsome species when well grown

A. hybridum (hybrid). *rhiz.* woody, densely clothed with dark chestnut-brown, crisped scales. *sti.* firm, erect, scaly, 6in. to 9in. long. *barren fronds* 6in. to 12in. long, about 2in. broad, acuminate, rounded at base, sub-coriaceous, scaly at the edges. *fertile fronds* much smaller. Tropical Africa. SYN. *A. Linbergii.*

A. latifolium. Other varieties of this species are: *angustifolium, callæfolium, conopodium, crassinerve,* and *Sartorii.*

A. laurifolium (Laurel-leaved). *cau.* firm, erect, naked. *fronds* pinnate, 3ft. long, 1½ft. broad, coriaceous; barren pinnæ 6in. to 9in. long, 1½in. broad, gradually narrowed from the cordate base, sharply but finely toothed; fertile ones a little longer, but seldom more than ¼in. broad, the lower ones 1in. to 2in. apart. Philippines, &c. A handsome species. SYN. *Stenochlæna laurifolia.*

A. laurifolium, of Thouars. A form of *A. conforme.*

A. Lechlerianum (Lechler's). *rhiz* woody, wide-scandent, scaly. *sti.* 6in. to 12in. long, firm, erect, scaly downwards. *fronds* 3ft. to 4ft. long, 1ft. to 1½ft. broad, the barren one quadripinnatifid; lower pinnæ 6in. to 9in. long, 4in. to 5in. broad; pinnules close, lanceolate; segments oblong, deeply lobed; rachises pubescent; fertile pinnules narrower, distant, the segments oblong-cylindrical, with a space between them, the lower ones rather beaded. Peru and Ecuador, 1886. SYN. *Polybotrya Lechleriana* (G. C. n. s., xxv., pp. 400-1).

A. Linbergii (Linberg's). A synonym of *A. hybridum.*

A. Lingua (tongue-like). This species differs from *A. latifolium* in the following points: *rhiz.* firm, wide-creeping or long-trailing, covered with small, ovate, dark brown scales. *fronds* coriaceous, suddenly narrowed at base. Tropical America. SYN. *Elaphoglossum Lingua.*

A. magnum (large). *rhiz.* sub-erect, the basal paleæ small, nearly black. *sti.* tufted, those of the barren fronds 3in. to 4in. long. *barren fronds* 2ft. to 3ft. long, 1½in. to 2in. broad, narrowed gradually to both ends, the paleæ of the upper surface numerous, minute, whitish, those of the under side ferruginous. British Guiana, 1880. SYN. *Elaphoglossum magnum.*

A. melanopus (black-footed). *rhiz.* short-creeping, densely covered with long, blackish or dark chestnut scales. *sti.* 2in. to 3in. long, also densely scaly. *barren fronds* 5in. to 8in. long, 2in. broad, elliptic-oblong, acute, rounded at base, coriaceous,

FIG. 14. ACROSTICHUM MUSCOSUM.

Acrostichum—*continued.*

scaly on the margins. Venezuela. SYN. *Elaphoglossum melanopus.*

A. muscosum. This beautiful species is illustrated in Fig. 14.

FIG. 15. ACROSTICHUM OSMUNDACEUM.

A. osmundaceum. Fig. 15 shows this handsome American species.

A. peltatum gracillimum (very slender). *fronds* larger and much more finely divided than in the type, than which it is of easier culture. Stove or greenhouse. The typical *A. Peltatum* is shown in Fig. 16.

A. Plumieri (Plumier's). A variety of *A. villosum.*

A. Prestoni (Preston's). *rhiz.* thick, woody, short-creeping. *sti.* 6in. to 9in. long, covered with brownish-black scales. *barren fronds* simple, 1in. to 1½in. long, 2in. broad, lanceolate, bordered on their whole length with a dense, persistent fringe of brown scales. Rio de Janeiro.

A. proliferum (proliferous) A form of *A. virens.*

A. Quoyanum (Quoy's). A variety of *A. repandum.*

A. repandum (uneven). *barren fronds* very decorative, 1½ft. to 2ft. long, 8in. to 12in. broad, sometimes elongated and rooting; pinnæ numerous, soft in texture, the lower ones 6in. long, 1in. broad. *fertile fronds* having stalked, bowed pinnæ 2in. to 3in. long. Tropical Asia. A robust species. SYN. *Gymnopteris repanda.*

A. r. Quoyanum (Quoy's). *fronds* having the pinnæ lobed half-way down or more, the lobes toothed.

A. Sartorii (Sartor's). A variety of *A. latifolium.*

A. setosum (bristly). A variety of *A. villosum.*

A. Smithii (Smith's). A variety of *A. sorbifolium.*

A. sorbifolium buxifolium (Box-leaved). *fronds* having the pinnæ sessile, coriaceous, dark green, oblong, very obtuse, less than 1in. long, ¼in. broad.

A. s. Smithii (Smith's). *fronds* sessile, tripinnatifid; pinnules numerous, small, dichotomously forked.

A. s. variabile (variable). *fronds* having the lower pinnæ deeply pinnatifid, with round, dented lobes.

A. tenuifolium (slender-fronded). A synonym of *Lomaria tenuifolia.*

A. terminans (terminating). A form of *A. virens.*

A. tomentosum (downy). *rhiz.* woody, with dense, black, fibrillose scales. *sti.* 3in. to 5in. long, rigid, erect, densely ciliated, scaly, the upper scales white. *barren fronds* 1ft. or more in length, 1in. to 1½in. broad, bluntish at apex, the lower part gradually narrowed, thick but flaccid, both sides matted with scales. *fertile fronds* narrower, on stems 1ft. or more in length. Bourbon.

A. undulatum (waved). A variety of *A. villosum.*

A. variabile (variable). *rhiz.* wide-creeping. *sti.* of barren fronds wanting or even 6in. long. *barren fronds* 6in. to 18in. long, 1½in. to 3in. broad, oblong-spathulate, with a very long, gradually narrowed

Acrostichum—*continued.*

haft, blunt or acute, entire, naked. *fertile fronds* 6in. to 12in. long, ¼in. to ¼in. broad, on stipes often 1ft. long. India.

A. variabile, of Fée. A variety of *A. sorbifolium.*

A. villosum. This species is very variable; among the principal deviations from the type may be named *A. Plumieri*, *A. setosum*, and *A. undulatum.*

A. virens (green). *rhiz.* hard, woody, short-creeping. *sti.* firm, erect, without scales. *barren fronds* coriaceous, 2ft. to 3ft. long, often 1ft. broad; lateral pinnæ 6in. to 8in. long, about 1in. broad, the edges bluntly lobed or sometimes sinuate; terminal one twice as long, generally rooting at the point. Tropical Asia. SYN. *Gymnopteris virens.* A very robust and decorative species, of which the following are merely forms: *A. contaminans*; *A. costatum*, pinnæ 8in. to 12in. long, 2in. to 3in. broad, tinged with red; *A. crispatulum*, pinnæ narrow, crisped, very coriaceous; *A. proliferum*, pinnæ broad; and *A. terminans.*

FIG. 16. ACROSTICHUM PELTATUM.

ACROTREMA (from *akros*, a point, and *trema*, a perforation; the pollen is shed through a hole at the tip of the anthers). ORD. *Dilleniaceæ.* A genus consisting of about a dozen species of almost stemless, stove or greenhouse herbs with a perennial or woody rhizome, natives of India, and especially plentiful in Ceylon. Flowers yellow; sepals five, spreading; petals five; filaments more or less aggregated in three bundles; peduncles axillary, loosely few-flowered or racemosely many-flowered. Leaves ample, pinnately lobed or dissected. For culture of *A. Walkeri*, the only species introduced, *see* **Delima.**

A. Walkeri (Walker's). *fl.* in very short, axillary racemes; stamens about fifteen; pedicels 1in. to 2in. long, laxly villous. June. *l.* narrowly obovate-oblong, bullate, 2in. to 4in. long, ¼in. to 1in. broad, sharply toothed, auricled at base, dull red and hairy on the veins beneath. Ceylon, 1851. Warm greenhouse. (B. M. 5353.)

FIG. 17. ACTINIOPTERIS RADIATA

ACTÆA. This genus embraces only the two species described on pp. 20-21, Vol. I., *A. spicata* (Herb Christopher) being broadly distributed over North temperate regions and indigenous in Britain. Several plants formerly included here are now referred to **Cimicifuga.**

A. dioica (diœcious). A synonym of *Xanthorrhiza apiifolia.*

A. palmata (palmate). A synonym of *Trautvetteria palmata.*

ACTINELLA. *Picradenia* is synonymous with this genus.

ACTINIDIA. About eight species, natives of the Himalayas, China, and Japan, are included hereunder.

ACTINIOPTERIS. The very decorative and attractive *A. radiata* (Fig. 17) and *A. r. Australis* (Fig. 18), with their striking Palm-like fronds, are erroneously considered as very difficult to manage, consequently they are not grown as extensively as they really deserve; they are most interesting, though of comparatively small dimensions. Failure in their culture must, in many cases, be attributed to the excessive heat to which they are subjected, which causes them to get "thrippy" and lose their vitality; but when kept in a temperature of 60deg. in the winter, raising to 70deg. in the summer, with constant moisture around them, they remain perfectly clean and healthy. They thrive best in fibrous peat, fibrous loam, broken in small pieces, coarse silver sand, and small crocks, in about equal proportions. It is also absolutely necessary that the pots in which these Ferns are grown should be half-filled with crocks, so as to insure perfect drainage, for they require frequent and abundant waterings to keep their roots in a permanently moist state all the year round. Being devoid of rhizomes or stems of any kind, Actiniopteris are usually propagated from spores, which germinate very freely when sown on a compost of brick-dust mixed with a little loam, and kept in a warm, close case. They may also be increased by the division of the crowns; but this operation, which should be done not later than the beginning of March, is of a somewhat risky nature, and requires a certain amount of experience and a good deal of attention to ensure the separate pieces getting established.

FIG. 18. ACTINIOPTERIS RADIATA AUSTRALIS.

ACTINOCARPUS. The correct name of this genus is **Damasonium** (which *see*).

ACTINOCHLOA. A synonym of **Bouteloua** (which *see*).

ACTINOLEPIS. SYN. *Hymenoxys.* This is the correct name of the genus described on p. 247, Vol. III., as *Ptilomeris*, and *P. coronaria* is properly known as *A. coronaria.*

ACTINOMERIS. SYN. *Ridan.* About nine species, natives of North America (including Mexico) comprise this genus.

A. alata. The correct name is *Verbesina occidentalis.*

A. procera is synonymous with *A. squarrosa.*

ACTINONEMA ROSÆ (SYN. *Asteroma radiosum*). A fungus responsible for the irregular black spots frequently seen on the foliage of roses in summer, causing it to turn yellow and prematurely fall in very bad attacks. Later these spots increase in size, and assume a more definite rounded form. Beyond removing the leaves and bare shoots and burning them little can be done, as the mycelium is in as well as upon the foliage. Where Roses are grown, and the disease was known to exist the previous season, it will be well to spray in spring, using a weak solution of **Bordeaux Mixture** (which *see*).

ACTINOSTROBUS (from *aktin*, a ray, and *strobos*, a cone; in allusion to the disposition of the cone-scales). ORD. *Coniferæ.* A small genus (two species) of greenhouse,

Actinostrobus—*continued.*

densely-branched shrubs, natives of South-western Australia. Flowers monœcious; amenta on very short peduncles, or almost sessile, in the axils. Cones ovoid-globular or acuminate, the six inner much-enlarged scales becoming almost valvate in a single whorl, with six or twelve of the outer barren scales more or less enlarged and closely appressed or adnate to their base. Leaves in whorls of three, very short, thick, rigid and acute, or those on the smaller branches appressed, obtuse, and three-angled. Only one of the species is known in our gardens. For culture *see* **Callitris** (to which this genus is closely allied).

A. pyramidalis (pyramidal). *fl.*, amenta one to three lines long. *cones* ½in. in diameter or more. *l.*, lower ones somewhat acicular and three to four lines long; those of the main branches acute and spreading, ⅛in. or less in length; those on the smaller branchlets still shorter, appressed and obtuse. A densely-branched, pyramidal, glabrous shrub.

ACTINOTUS. SYN. *Eriocalia.* Seven species are included in this genus. *A. Helianthi* is figured in B. R. 654, and as *Eriocalia major* in S. E. B. ii., t. 38.

ACULEATE HYMENOPTERA. This is a most important section of the Order *Hymenoptera*—an order which, judged by the intelligence displayed by the majority of its members, should be placed at the head of those which go to make up the Class *Insecta*. The insects falling under the above denomination are those which bear a sting. Many of them are amongst the most familiar of garden insects—Social Bees, Social Wasps, and Ants, for instance—and play a very important part in the economy of Nature. There are still others inhabiting gardens which are more readily passed over, useful though they be. Such are the Solitary Wasps, which provision their nests with caterpillars (usually of noxious species of moths) and spiders. Of these there are no less than twenty-nine species in two genera, *Eumenes* and *Odynerus*, mostly inhabiting sandy localities. All are not equally common. They are small in comparison with the Social Wasps, but prettily banded with yellow on black. They are further distinguished by a more or less narrow pear-shaped body, and by the tarsal hooks, which are simple in the Social and hooked in the Solitary Wasps.

Aculeate Hymenoptera are thus divided by Mr. S. Saunders: *Heterogyna*, *Fossores*, *Diploptera*, and *Anthophila*. The *Heterogyna*, or Ants, are insects whose economy is fairly well understood, and whose conformation is familiar. They are injurious insects to the gardener. The *Fossores*, or diggers, are friends; the insects comprising it usually burrow in the sand, and are carnivorous. Some species are frequently mistaken for Wasps, though they should readily be distinguished therefrom by the disposition of the wings, which in Wasps are folded (hence *Diploptera*) longitudinally when at rest; whereas those of the *Fossores* never are.

The *Diploptera*, or Wasps, are further sub-divided into *Vespidæ* and *Eumenidæ*. The former includes the Social Wasps, all of which, save the Hornet, are pests to the gardener, the good they do being quite discounted by the injury to the ripening fruit; and the latter the Sand Wasps, all of which are useful to the gardener.

Another useful genus in this group is that known as *Ammophila*. These insects have a markedly long petiole connecting the abdomen with the other parts of the body, and are in length from ½in. to ¾in., and variously coloured. The long petiole ought, however, to distinguish them as friends to the gardener; for like their relatives the Solitary Wasps, they furnish their nests with caterpillars, &c., to feed the larvæ when they hatch out. Then there are others which provision them with Aphides, or their near relatives—for instance, members of the genera *Psen* and *Mimesa*.

The last section of the Aculeates to be noticed is *Anthophila*. This contains not only the Hive Bee, but also many others which are not so well known, or their economy so perfectly understood. There are Social Bees

Aculeate Hymenoptera—*continued.*

and Solitary Bees, as there are Social Wasps and Solitary Wasps. Some of the Solitary Bees, in particular, are much maligned by gardeners and others, and are credited with injury they never inflict. *Anthidium manicatum* is a case in point. This is a locally distributed insect which is popularly supposed to destroy wood by boring into it; as a matter of fact this latter is untrue. What the Bee really does is to tenant some hole which has previously been occupied by another insect, and industriously line its nest with woolly substances laboriously collected from various parts of plants. It is deftly rolled up and then carried away. To this section also belongs the Corder Bees (certain *Bombus* species) whose nests are built upon the ground, and then carefully protected by grass, moss, or what not. These latter are Social Bees.

Other Solitary Bees unfavourably regarded by gardeners are the Leaf-Cutters, *Megachile circumcincta* and *M. centuncularis*. Clever insect-architects though they be, and undeniably ingenious, as they, with unerring aim and mathematical accuracy, remove from Rose-leaves (see Fig. 19), or it may be from Scarlet Pelargonium flowers, almost elliptical pieces that will fit into the required space of their nest lining, and carry it off, they are undesirable in gardens. The work is always that of the female, as the male takes no part in the provision of a home. Usually the insect steers clear of the midrib of the leaflet, but occasionally a portion of this also is removed. The piece of foliage is gradually detached with the insect in position on it, though the actual severance is made while she is on the wing. The whole operation occupies but very few seconds; while the pieces removed are identical in size. The former is a sand-loving insect, and local in its distribution, although in Surrey it may be plentifully found. For Marechal Niel Rose foliage it has a particular affection. The latter is common, and occasionally lays the Scarlet Pelargonium flowers under contribution to line its nest.

FIG 19. ROSE FOLIAGE ATTACKED BY LEAF-CUTTING BEES.

ADA. These charming orange-scarlet flowered Orchids thrive well under similar conditions to that recommended for **Odontoglossum.** They do best grown in pots, which should be placed within a reasonable distance of the roof-glass, where the plants can obtain a liberal amount of light and a free circulation of air whenever the outside conditions permit. Fibrous peat and living sphagnum make a good potting compost. Adas require a liberal supply of moisture at the root at all seasons of the year. To the species described on p. 22, Vol. I., the following should be added:

A. Lehmanni (Lehmann's). *fl.*, sepals and petals orange; lip white, with a yellow callus. Colombia, 1891. This is distinguished from *A. aurantiaca* by its white lip, shorter, broader, and darker green leaves everywhere marbled with grey, and more rigid habit; further, the flowers are produced in the summer.

ADAMIA. The three plants described under this name are all referred by Bentham and Hooker to one species, forming the genus **Dichroa** (which *see*).

ADAM'S FLANNEL. *See* **Verbascum Thapsus.**

ADANSONIA. SYN. *Ophelus.* Two species form this genus; both are stove trees, with dwarf trunks of enormous girth. Flowers white, large, pendulous; calyx ovoid or oblong, deeply five-cleft; petals five, obovate or oblong; peduncles axillary, one-flowered. Fruit oblong, woody, indehiscent, containing mealy pulp (Monkey Bread). Leaves digitate; leaflets three to nine, entire.

ADDER'S VIOLET. *See* **Goodyera pubescens.**

ADELASTER ALBIVENIS. The plant exhibited and described under this name (Proc. R. Hort. Soc., 1861, p. 568; I. H. t. 320) is probably some kind of *Eranthemum.*

ADELGES ABIETIS. *See* **Spruce-Gall Aphis.**

ADELIA (from *a*, not, and *delos*, visible; in allusion to the minute parts of the fructification). SYN. *Ricinella.* ORD. *Euphorbiaceæ.* A genus embracing about seven species of stove shrubs, natives of the West Indies and Central America. Flowers small, dicœcious, apetalous. Leaves alternate or crowded at the nodes, entire, shortly petiolate. A few of the species have been introduced, but they are of no particular horticultural value.

ADELMANNIA. A synonym of **Borrichia** (which *see*).

ADELOBOTRYS. SYN. *Truncaria.* Eight species, natives of Mexico, Colombia, North Brazil, Guiana, and Jamaica, have been referred to this genus.

ADENANDRA. SYN. *Glandulifolia.* Of this genus there are upwards of twenty-one species. Several of them were formerly classed under *Diosma; e.g., A. fragrans* (B. M. 1519), *A. umbellata speciosa* (B. M. 1271), and *A. uniflora* (B. M. 273).

A. linearis is a variety of *A. uniflora.*

ADENANTHERA. SYN. *Stachychrysum.* Three or four species, natives of tropical Asia, Africa, and Australia, are included in this genus, one being broadly cultivated in the warmer regions of the globe.

ADENEMA. A synonym of **Enicostema** (which *see*).

ADENILEMA. A synonym of **Neillia** (which *see*).

ADENOCARPUS. About eight species, natives of South and South-west Europe, tropical and North Africa, and the Canary Islands, are included in this genus; several of them were formerly classed under *Cytisus.* To those described on p. 23, Vol. I., the following should be added:

A. Anagyrus (Anagyris). A synonym of *A. frankenioides.*

A. decorticans (barkless).* *fl.* bright yellow, Pea-like, in short, compact racemes. May. *l.* densely set, two or three-foliolate; leaflets linear, soft, dark green. Spain, 1883. A beautiful, half-hardy, evergreen shrub, having the general aspect of Furze. (G. C. n. s., xxv., p. 725; Gn., 1886, p. 572; R. H. 1883, p. 156.)

ADENOCREPIS. A synonym of **Baccaurea** (which *see*).

ADENOPHORA. SYN. *Floerkia* (of Sprengel). Gland Bellflower. This genus embraces about ten distinct species, natives of temperate Asia and Western Europe.

A. coronata (crowned). A synonym of *A. intermedia.*

A. Potanini (Potanini's). *fl.* pale blue, bell-shaped, in elegant, slender spikes. *h.* 2½ft. Shrubby.

ADENOPODIA. A synonym of **Entada** (which *see*).

ADENOSMA (from *aden*, a gland, and *osme*, smell; alluding to the glands in most of the species which exhale a Mint-like odour). SYNS. *Anisanthera* (of Griffith), *Pterostigma.* ORD. *Scrophularineæ.* A genus embracing

Adenosma—*continued.*

about seven species of stove, glandular-pubescent or villous herbs, often aromatic, natives of the East Indies, Eastern Asia, the Malayan Archipelago, and Australia. Flowers blue, on very short pedicels; calyx five-parted; corolla tube cylindrical, the posterior lip erect, entire or emarginate, the anterior one spreading, entire or three-lobed; stamens four, included. Leaves opposite, wrinkled, crenulate. Only one species is known to cultivation. It thrives in a compost of sand and peat, and may be increased by seeds or by divisions.

P. grandiflorum (large-flowered). *fl.* violet, the lower ones axillary, the upper ones racemose; calyx ¼in. long; corolla 1in. long; pedicels shorter or longer than the calyx. *l.* petiolate, ovate, 1½in. to 2in. long, or the lower ones larger. *h.* 1ft. to 2ft. China, 1845. SYN. *Pterostigma grandiflorum* (B. R. 1846, t. 16).

ADENOSTEMMA (from *aden*, a gland, and *stemma*, a crown; in reference to the fruit being crowned by glandular awns). SYN. *Lavenia.* ORD. *Compositæ.* A genus comprising not more than five distinct species, mostly natives of the warmer parts of America, one being broadly dispersed over the globe. Flower-heads white, mediocre or small, homogamous, loosely corymbose, paniculate; florets tubular. Leaves opposite, petiolate, toothed or almost entire. *A. viscosum* (B. M. 2410, under name of *Ageratum strictum*) has been introduced, but is probably lost to cultivation.

ADENOSTYLES (from *aden*, a gland, and *stylus*, a style; in allusion to the long stigmas being covered with warty glands). ORD. *Compositæ.* A genus embracing three or four species of tall, hardy, perennial herbs, natives of Central and Southern Europe. Flower-heads homogamous, mediocre or rather large, disposed in an ample, corymbose panicle; florets purplish or whitish, rather long-exserted; involucre cylindrical-campanulate; receptacle flat, naked. Leaves alternate or radical, long-petiolate, often broad; petioles often dilated into stipule-like auricles at the base. Three species are in cultivation. They thrive in any fairly good soil, and may be increased by seeds or by divisions.

A. albifrons (white-leaved).* *fl.-heads* composed of three to six florets; involucre glabrous; corymb fastigiate. July and August. *l.* reniform-cordate, coarsely and unequally duplicate-toothed, somewhat tomentose beneath. Woody mountains.

A. alpina (alpine). *fl.-heads* composed of three to six florets. *l.* glabrous underneath, or hairy on the nerves; petioles rarely auricled.

A. leucophylla (white-leaved). *fl.-heads* in a compact corymb; florets ten to twenty on a head. *l.* white, tomentose on both sides. High Alps.

ADENOSTYLIS (of Blume). A synonym of **Zeuxina** (which *see*).

ADENOTRICHIA. Included under *Senecio, A. amplexicaulis* being now known as **S. Adenotrichia** (which *see*).

ADESMIA. About 110 species have been referred to this genus, but scarcely more than eighty are entitled to rank as such. To those described on p. 24, Vol. I., the following should be added:

A. balsamica (balsamic). *fl.* golden-yellow, ⅜in. in diameter; racemes terminal, effuse, three- to eight-flowered. March. *l.* 1in. to 1½in. long, shortly petiolate, pinnate; leaflets ten to thirteen pairs, ⅛in. to ¼in. long, sessile, dark green, oblong or cuneately obovate. Branches very slender, leafy. Chili, 1887. A nearly glabrous, excessively-branched shrub, covered with balsamic glands. (B. M. 6921.)

ADHATODA. SYN. *Duvernoia.* This genus embraces half-a-dozen species, natives of India, Africa, and South America. Flowers whitish or purple; calyx five-cleft; corolla having a short tube and a long bilabiate limb; stamens two; bracts and bracteoles spreading, often much exceeding the calyx. Leaves entire. *See also* **Justicia**, under which are now classed several species that were formerly included under *Adhatoda.*

ADIANTUM. Including *Hewardia*. This genus includes upwards of eighty species, "most of which are recognisable from all other Ferns but the typical Lindsayas by the texture, as also by the one-sidedness of their segments, and by the absence of an apparent and distinct midrib in their segments" (Schneider). Stipes and rachises usually black and glossy. Fronds varying from simple to decompound; pinnæ usually truncate, wedge-shaped at base, or dimidiate and soriferous only on the upper margin; veins simple, radiating, forked, anastomosing only in four species (section *Hewardia*).

Adiantums are, as a rule, easy to manage. Plenty of light should be allowed all of them, but, as with nearly all other Ferns, the full rays of the sun should be carefully avoided. A mixture of fibrous peat, or of partly-decayed leaf-mould, loam, and silver sand, in about equal parts, will suit most of them. None of them like to be potted very hard, and watering or syringing overhead, unless it be in a very airy, light, and warm house, is injurious to most of them.

The propagation of all kinds of Adiantums provided with running rhizomes may with advantage be effected by the division of the same, an operation which is best performed from February to April. Species with tufted crowns may also be increased by division, but in their case, and especially when quantities of plants are required, it is safer and more advantageous to depend on spores, which germinate freely, and which usually produce stronger and more shapely plants than those resulting from the division of the crowns. The spores may be sown with perfect safety at all times of the year, although the most favourable season is from January to April, as in that case the seedlings have ample time to produce crowns sufficiently strong to withstand the effects of the following winter.

There is scarcely any need to enlarge upon the many ways in which the Maidenhair Ferns may be utilised for bouquets, wreaths, &c., to refer to their value as decorative subjects, or yet again to their diversity of form and tint, though the last-named are not so well known as the other characteristics. There are numerous dwarf-growing forms of *A. cuneatum* and of *A. Capillus-Veneris*, all very pretty, and equally useful for edgings in the Fernery. Then there are, besides the light-coloured *A. polyphyllum*, with its gigantic fronds, the deservedly-popular *A. trapeziforme*, *A. peruvianum*, *A. Seemanni*, and others too numerous to be mentioned here. Again, we have some whose shape and general habit are totally different from ordinary Adiantums: such, for instance, as the curious *A. reniforme* (see Fig. 20), with its kidney-shaped fronds borne on slender, shining stalks; or the lesser-known *A. asarifolium*, with broad, entire fronds perfectly round, and measuring sometimes as much as 3½in. across. Very strange, also, is the general appearance of *A. Fëei*, whose climbing fronds expand to very great dimensions, and whose stalks are quite hairy and of a peculiarly ferruginous colour. There are also kinds whose fronds are of a metallic hue, and numerous others, such as *A. macrophyllum* (see Fig. 21), *A. tinctum*, &c., which

FIG. 20. ADIANTUM RENIFORME

Adiantum—*continued.*

are exceedingly interesting because of the beautiful rosy colour of their splendidly-tinted young fronds. Then there are the golden and silvered forms of *A. æthiopicum*, which of late years have become exceedingly rare; as well as the pendulous *A. caudatum* and *A. lunulatum*, so well adapted for basket-culture. With plants so diverse in character, a collection composed exclusively of Adiantums would be most interesting.

Mention has already been made of one or two kinds specially useful for basket-culture; there are, however, several others quite as desirable if their requirements are understood. *A. lucidum* is considered one of the best basket Ferns. The fact of it being deciduous accounts for its disappearance in many cases, as care must be taken during the winter that it does not become thoroughly dry, or it will never start into growth again It does much better if kept moderately moist at the roots all the year round. Although by this system of culture it does not get so much rest as if treated as a deciduous plant, it usually starts much stronger into growth in the spring. *A. Williamsii* is essentially a basket-plant, and it is especially for that purpose that it is most valuable; the more so that it is one among the very few Adiantums which really make a good, effective basket for the greenhouse.

FIG. 21. ADIANTUM MACROPHYLLUM.

A. palmatum, again, by reason of the flexuose character of the rachis, most marked towards the terminal end of the frond, is particularly well adapted for basket culture. Grown in that way it soon makes a very handsome plant, specially attractive through the pale-green colour of its foliage. Though deciduous, losing its fronds about November and starting into fresh growth about March, it should not at any time be allowed to get quite dry at the roots.

Hints as to the treatment that Adiantums generally should receive have been given. There are some few species which are notoriously difficult to grow. These it will be better to refer to specifically. First, as to *A. reniforme*. By most growers this species is considered difficult to manage; but it is generally when kept in too warm a house, or when potted in too loamy a soil, that it gives trouble. To be grown successfully it only requires greenhouse treatment, and it thrives best in a mixture of two parts peat, one part fibrous loam, and one part coarse silver sand (or, when procurable, one part of old lime rubbish, of which its roots are very fond). *A. cristatum* is seldom seen in perfection. It requires less water at

Adiantum—*continued.*

the roots than the majority of Adiantums, is very partial to lime rubbish, and should be grown in a somewhat dry part of the house

FIG. 22. PORTION OF FROND OF ADIANTUM TENERUM FARLEYENSE.

A. tenerum Farleyense (see Fig. 22) is a kind with which the grower's difficulties are more imaginary than real. Heat and moisture are the essential requirements of this plant, and it will not succeed where either of these is deficient, though it may be safely wintered in a house with a temperature of 60deg., occasionally falling to 55deg. In structures where this minimum temperature cannot be maintained in winter, the plants do not die off altogether, but they suffer so severely that several months of careful nursing are required to restore them to their former strength. As regards soil, this Adiantum is not so difficult to please as is supposed. Two parts of good fibrous peat and one of fibry loam and coarse silver sand together form a compost in which it will succeed; but plants in no way inferior have been grown entirely in pure, light fibrous loam, commonly called "yellow loam."

If in some places in England failure has attended the attempt at acclimatising *A. pedatum* outside, it is due to the fact that the underground rhizomes are generally kept too close to the surface of the ground, and that they are not protected in winter by either leaves or snow, and thus feel more keenly the effects of cold, though less severe than that of its own country. Although it is a perfectly hardy Fern, yet, like the other so-called hardy Adiantums, it never grows so luxuriantly out of doors as it does in the greenhouse. Some of the Continental growers yearly produce remarkably handsome plants of this species in large quantities by inserting in early spring, round the edges of their rhododendron beds, small specimens of it, which form good clumps during the summer season. These are lifted from the ground about January, put in 5in. or 6in. pots, and placed in houses or frames in which the temperature is between 40deg. and 60deg. The crowns soon start into growth, and produce a crop of foliage which, on account of its pleasing light green colour and elegant shape, makes the Fern one of the most effective in the conservatory, as it is later on for the rockery or for a shady nook outside.

Although classed among our native Ferns, the British Maidenhair (*A. Capillus-Veneris*) is too tender to bear a very cold temperature: the least frost injures it, and a severe frost kills it. It is a very accommodating plant, and not at all fastidious in its habits, for it grows equally well in a heated frame, in a greenhouse, or in the moist, shady part of a stove. In Europe, it is essentially a coast plant, being found growing exclusively in caves

Adiantum—*continued.*

and fissures of rocks near the sea-level, generally in a shady situation where there is an abundant supply of moisture. When grown in pots, an abundant drainage is essential, and the soil which it prefers is a compost of turfy peat, leaf mould, and lime rubbish, in equal parts; it is also necessary that the rhizomes should be kept on the surface of the soil. And what has been said of the type holds good with the interesting and handsome varieties which have been produced.

Just as there are some rather difficult species to manage in the genus *Adiantum*, so are there some whose culture is of the easiest. Such is *A. cuneatum*, which requires less attention than almost any other Fern, and thrives in almost any soil, although it prefers a rich, light compost. It is not very particular as to temperature, and, provided regular moisture at the roots be kept up, it will produce all through the year an immense quantity of its useful fronds from a tufted crown. It is so readily propagated from spores that wherever it is grown a stock of young plants spring up. Also of easy cultivation is *A. Henslovianum*, but, being entirely deciduous, it requires a period of rest from November to February, when it is almost, if not entirely, leafless.

To the species and varieties described on pp. 24-9, Vol. I., the following should be added:

A. asarifolium (Asarum-leaved). A variety of *A. reniforme.*

A. assimile cristatum (crested). *fronds* elegantly crested. 1887. Garden variety.

FIG. 23. ADIANTUM BIRKENHEADII.

A. Birkenheadii (Birkenhead's). *fronds* tripinnate, about 2½ft. long and 1ft. broad, deltoid, acuminate; pinnæ alternate, distant and long-stalked towards the base, closer together and sessile near the apex, the lower ones bipinnate, the upper ones pinnate; pinnules obtusely oblong-trapezoid, cut on the upper edge into shallow lobes. 1886. A fine garden Fern, of tufted habit. Intermediate house. See Fig. 23.

A. Bournei (Bourne's). A variety of *A. cuneatum.*

A. brasiliense (Brazilian). A form of *A. curvatum.*

A. bulbiferum (bulb-bearing). A variety of *A. Capillus-Veneris*

Adiantum—*continued.*

A. Burnii (J. B. Burn's). *sti.* smooth, ebeneous. *fronds* evergreen, glabrous, broadly ovate, acuminate, tri- or quadripinnate; pinnæ ovate, the lower ones with a long stalk, the upper ones almost sessile; pinnules stipitate below, the basal one 2in. to 2½in. long, narrowly ovate, the basal pinnulets compound, the upper ones still narrower because less divided at the base. *sori* numerous, roundish-reniform, seated at the base of a notch at the apex of the lobes. 1887. Garden hybrid. Stove.

A. Capillus-Veneris bulbiferum (bulb-bearing). A variety having little bulbils on the pinnæ—probably the only Adiantum possessing that character.

A. C.-V. cuneæformis (wedge-shaped). *fronds* very long, rather narrow, and loose. 1896. A very graceful, garden form.

A. C.-V. depauperatum (poor). *fronds* erect, narrow, about 1ft. long; pinnules much cut, in some cases reduced to thread-like segments. An interesting sport or natural hybrid.

A. C.-V. digitatum (digitate). *fronds* not symmetrical, but with a tendency to become unequally ovate, dwarfish, smooth, evergreen; pinnæ and pinnules unequal and irregular, the more perfect pinnules rhomboid, with a rounded apex, deeply furcate-lobed, the edges marginate. *sori* wanting. A curious variety.

A. C.-V. grande (large). A very handsome variety, larger, denser, and more bushy in habit than the type. 1886. Hardy.

A. C.-V. Hookeri (Hooker's). *fronds* erect; pinnæ and their ultimate sub-divisions disposed alternately, the latter cuneate at base and very finely toothed at the summit, which is rounded or fan-shaped. Crimea.

A. C.-V. imbricatum (imbricated). *sti.* and rachises glossy ebeneous. *fronds* ovate, 6in. long, densely imbricated, bi- or tripinnate, evergreen; pinnæ crowded, 2in. to 2½in. long, 1½in. wide; pinnules large, much overlapping, the lateral ones rhomboid, ⅔in. long and ½in. broad, the terminal ones broadly flabellate, 1in. or more in width. *sori* elongate-oblong. 1887.

A. C.-V. Kalon (Kalon). *fronds* ovate, 11in. long, 5in. broad, arching; pinnules very leafy and closely set. One of the few forms artificially raised from spores in this country.

A. C.-V. obliquum (oblique). *fronds*, pinnæ very large, oblique. 1885. (I. H. 1885, 546.)

A. C.-V. ramulosum (full of small branches). *fronds* having the main stem twice or thrice divided towards the summit, forming a spreading tuft of short, pinnate branches; pinnules in the lower portion narrow and depauperated. An extraordinary variety.

A. Catherinæ (St. Catherine's). A synonym of *A. trapeziforme Sanctæ-Catherinæ.*

A. chilense (Chilian). A form of *A. æthiopicum.*

A. Clæsianum (Claes'). *fronds* composed of rhomboid pinnules, which are pale green, with a silver blotch at the base and silver

FIG. 24. ADIANTUM CONCINNUM.

Adiantum—*continued.*

lines radiating to the bluntly-toothed margins. South America, 1894. A charming, stove Maidenhair. (I. H. 1894, p. 137, t. 9.)

A. Collisii (Collis'). *sti.* black, slender, 1ft. to 1½ft. long. *fronds* triangular, 1½ft. to 2ft. across; pinnules small, rhomboid, truncate on the inner and lower sides, and slightly toothed on the outer and upper margins. 1885. A beautiful, decorative, stove Maidenhair, of garden origin.

A. colpodes roseum (rosy). In this variety the young fronds are of a rich coppery-red tint. 1888.

A. concinnum. An illustration of this charming tropical American species is given in Fig. 24.

A. cornubiense (Cornish). A form of *A. Capillus-Veneris.*

A. cultratum (knife-like). A variety of *A. trapeziforme.*

A. cuneatum Bournei (Bourne's). *sti.* long. *fronds* dense, triangular. 1882. A garden variety in the way of *A. c. Pacotti*, but less refined in growth.

A. c. deflexum (deflexed). *fronds* triangular, three or four times pinnate; pinnules deflexed, lobed; lobes crenate-toothed. 1884. A garden hybrid between *A. Bausei* and *A. cuneatum.* Stove.

A. c. elegans (elegant). *sti.* glossy, 6in. long. *fronds* triangular, about 9in. long and broad; pinnæ ovate-triangular, with rather distantly-set, cuneate pinnules, which are ¼in. long and ⅛in. broad. Gardens, 1885. Stove.

A. c. fasciculatum (fascicled). A variety with crested fronds. 1897.

FIG. 25. ADIANTUM CUNEATUM GRANDICEPS.

A. c. grandiceps (large-headed). A crested variety, of drooping habit, well adapted for basket culture. See Fig. 25.

A. c. Lambertianum (Lambert's). A variety having the very small ultimate segments much crumpled and curled. 1890.

A. c. Pacotti (Pacott's). *fronds*, pinnules overlapping each other to an uncommon extent. Habit very dense.

A. c. strictum (upright). *fronds* erect, four times pinnate; pinnæ ascending, arranged somewhat spirally. 1884. Stove.

A. c. versaillense (Versailles). *sti.* branched for about two-thirds of their length. *fronds* erect, seldom exceeding 10in. in height, crested as in *grandiceps*, but much denser and more regular; pinnules of a pleasing light green. 1889. A valuable pot-plant, also useful for cutting and for decoration.

A. curvatum brasiliense (Brazilian). *rhiz.* stout, very slowly creeping. *sti.* hairy and brown. *fronds* often 3ft. in height, pubescent; pinnæ dark green, smooth, shorter, broader, blunter, and not so closely set as in the type. A very distinct variety.

A. cyclosorum (having circular sori). *sti.* stoutish, glossy black, 8in. to 10in. long. *fronds* 1½ft. to 2ft. long, triangular, tripinnate, glabrous; pinnæ spreading, ovate, stalked; pinnules five to nine lines long, rhomboid. *sori* eight to ten to a pinnule, circular,

Adiantum—*continued.*

marginal. Ecuador, 1887. A handsome and well-marked, deciduous, stove species.

A. Daddsii (J. Dadds'). *sti.* glossy ebeneous, about 8in. long. *fronds* above 1ft. long, fertile throughout, deltoid, decompound, evergreen, glabrous; pinnæ triangular-ovate, stipitate, furnished with numerous but not crowded pinnules; ultimate segments very numerous, quite small, distinct, everywhere pedicellate, the terminal ones cuneate with two or three lobes at the apex, the intermediate ones rhomboid-cuneate, more or less deeply lobed on the anterior side, the basal ones roundish or obovate, narrowed into the pedicels. *sori* roundish-reniform, situated in a notch at the apex of the marginal lobes. 1887. A supposed hybrid. Greenhouse.

A. daphnites (glistening). A variety of *A. Capillus-Veneris.*

A. deflexum (deflexed). A variety of *A. cuneatum.*

A. elegans (elegant). A variety of *A. cuneatum.*

FIG. 26. ADIANTUM FERGUSONI.

A. elegantissimum (most elegant). A sport from *A. cuneatum.*

A. excisum nanum (dwarf). *fronds* not more than 8in. high, rigid, produced in great abundance from a densely-tufted crown, tripinnate; pinnules cuneate, closely set. A garden variety, useful for edgings or for pot-culture.

A. fasciculatum (fascicled). A variety of *A. cuneatum.*

A. Fergusoni (Ferguson's).* *sti.* long, glossy purplish-black. *fronds* triangular-ovate, tripinnate, stiffly erect; pinnæ long-stalked, spreading; pinnules variable, mostly large, bluntly ovate, truncate at base, with a pair of large basal lobes, and three or four smaller lobes above, the pedicels continuous with the rachis, not articulated, all the lobes again lobulate, and, where sterile, finely toothed. *sori* oblong, at the tops of the ultimate lobes. Ceylon, 1884. Stove. See Fig. 26. (G. C. ser. iii., vol. ii., p. 469.)

A. festum (pleasant). *sti.* 8in. to 9in. long, purplish-ebeneous. *fronds* 1ft. long, glabrous, evergreen, decompound, drooping, triangular, acuminate; pinnæ deltoid, spreading; pinnules of ultimate segments small, crowded, cuneate or rhomboid-cuneate, larger towards their extremities, the terminal ones symmetrically or unequally cuneate, bipartite, with deeply-lobed divisions, the rest lobed on their anterior edge. *sori* roundish-reniform, placed in a sinus of the lobe. 1887. Greenhouse hybrid.

A. Footi (Foot's). A variety of *A. Capillus-Veneris.*

A. fragrantissimum (very fragrant). *sti.* 5in. to 6in. long, glossy ebeneous. *fronds* 1ft. to 1¼ft. long, deltoid, quadripinnate, glabrous, evergreen; pinnæ ovate, spreading, the basal ones long-stalked; ultimate pinnules or pinnulets large, on long, slender pedicels, cuneate, the terminal ones equally lobed at the apex, the lateral ones more or less obliquely cuneate, lobed. *sori* roundish-reniform, placed in a sinus at the apex of the lobes. 1887. Probably a hybrid. Stove. Reason for specific name not stated. (G. C. ser. iii., vol. ii., p. 199.)

A. Funckii (Funck's). A sub-variety of *A. trapeziforme.*

A. gracillimum nebulosum (cloud-like). A very pretty garden form, having fronds still finer and more delicate than in the type. 1893.

A. grandiceps (large-headed). A variety of *A. cuneatum.*

A. Hemsleyanum (Hemsley's). A distinct seedling, of elegant habit, having tall fronds, which are graceful, light in texture, pale green, with elongated-cuneate pinnæ not too closely set. Very useful as a pot plant. 1894.

A. Hendersoni (Henderson's). A variety of *A. tetraphyllum.*

A. hians (gaping). *sti.* black. *fronds* about 10in. long, triangular-ovate, tripinnate; pinnæ ovate, the upper ones stalked, the lower ones almost sessile; pinnules variable, roundish, balloon-shaped, transversely oblong, or rhomboidal, the end rounded, bearing one or two large, broadly-gaping sori. South Pacific Islands, 1887. An ornamental, stove Maidenhair.

A. Kaulfussii (Kaulfuss's). *sti.* wiry, upright, polished, blackish, 6in. to 9in. long. *fronds* 6in. to 12in. long, 3in. to 4in. broad, consisting of a large terminal lobe and eight or ten pinnæ on each side; lowest pinnæ 2in. to 3in. long, cordate and auricled at base, shortly stalked, those of the barren fronds slightly toothed. *sori* in interrupted marginal lines. West Indies, &c. Stove.

A. Lambertianum (Lambert's). A form of *A. cuneatum.*

A. lineatum (lined). A variegated form closely resembling *A. Cæsianum*, the fronds being marked with narrow pale lines. Brazil, 1895. (I. H. 1895, p. 312, t. 44.)

A. macrophyllum albo-striatum (white-striped). *fronds* pale green, with numerous white stripes and spots. 1894. A dwarf variety.

A. m. bipinnatum (bipinnate). This handsome variety differs from the type in having the fronds twice-pinnate in the lower part, and with smaller pinnules. Jamaica, 1885.

A. Mairisii (Mairis'). *fronds* triangular, quadripinnate; pinnæ ovate, on rather long stalks; pinnules cuneate-trapezoid, with an irregular, truncate apex, those near the ends of the pinnæ larger, with a lobate margin, the fertile ones cut into oblong, concave sinuses, giving a bluntly cornute aspect to the principal pinnule. 1885. Stove. Garden variety; perhaps a hybrid between *A. Capillus-Veneris* and *A. cuneatum.*

A. manicatum (having sleeves). This is described as a "seedling with bold, broad fronds and much-divided pinnules." 1890.

A. Matthewsianum (Matthews'). A synonym of *A. polyphyllum.*

FIG. 27. ADIANTUM MONOCHLAMYS.

A. monochlamys.* The habit of this beautiful Japanese species, which is allied to, but distinct from, *A. venustum*, is shown in Fig. 27.

A. Moorei plumosum (feathery). A charming plumose form for either pans or pots. 1894.

A. nebulosum (cloud-like). A form of *A. gracillimum.*

A. novæ-caledoniæ (New Caledonian).* *cau.* tufted. *sti.* and rachis blackish-purple, the latter clothed with dark brown hair-scales. *fronds* pedately pentagonal in outline, tripinnate at the basal part, bipinnate above; pinnæ narrow-lanceolate, the larger ones caudate; pinnules irregular in size and form, coarsely toothed, the largest 1in. to 1½in. long. New Caledonia. 1883. Stove. See Fig. 28, for which we are indebted to Messrs. W. and J. Birkenhead.

A. obliquum minus (lesser). *sti.* black. *fronds* pinnate; pinnæ falcate, acuminate, the sterile ones incised-toothed, the fertile ones with close-set, oblong sori, the apex trapeziform and lobed. 1883.

A. Oweni (Owen's). *sti.* about 8in. long, glossy ebeneous. *fronds* about 1¼ft. long, triangular-ovate, evergreen, glabrous, erect, quadripinnate; pinnæ ascending, triangular, stipitate, the lower ones on stalks about 1in. long, the upper ones gradually shorter;

Adiantum—*continued.*

basal pinnules ovate; pinnulets very small, shortly stipitate, slightly lobed, the terminal ones cuneate, the others mostly rhomboid. *sori* two to four to a pinnule, placed in a sinus of the marginal lobes. 1837. Stove hybrid.

A. Pacotti is a variety of *A. cuneatum.*

A. Paradiseæ (Miss Paradise's). *sti.* and rachis slender, naked, brownish-black. *fronds* deltoid, tripinnate, glabrous, 6in. long and nearly as broad; lower pinnæ deltoid, unequal, cut away on the lower side at base, conspicuously petiolate; ultimate segments rhomboid, ¼in. to ½in. long. *sori* one to three to a segment, broadly reniform, one to two lines long. Cape Colony, 1889. Greenhouse.

A. pentadactylon (five-fingered). A variety of *A. trapeziforme.*

Adiantum—*continued.*

A. roseum (rosy). *fronds*, when young, rosy-tinted. A dwarf, garden variety. Greenhouse.

A. Sanctæ-Catherinæ (St. Catherine's) A variety of *A. trapeziforme.*

A. scabrum (scurfy). A variety of *A. æthiopicum.*

A. schizophyllum (cut-fronded). *sti.* and rachises remote in varying degrees. *fronds* numerous, with stoutish, conspicuous, ebeneous rachises; pinnules small, commonly minute, most of them deeply cut into narrow lobes. *sori* small, lunate, sparingly produced in a perfect state. 1837. Stove or greenhouse. Although stated to be a seedling from *A. æmulum*, this is doubtless a form of *A. cuneatum.*

A. Schneideri (Schneider's). A handsome Fern, of graceful

FIG. 23. ADIANTUM NOVÆ-CALEDONIÆ.

A. plumosum (feathery). *fronds* about 8in. long, pale green. 1894. A pretty Maidenhair, of compact habit, resembling *A. fragrantissimum* and *A. cuneatum Pacotti.*

A. Reginæ (Queen's). *sti.* slender, black, shining. *fronds* shorter, broader, and more leathery than in *A. Ghiesbreghtii* (one of the supposed parents of this hybrid). *sori* sparingly produced, oblong, in an interrupted row round the outer margin. 1837. Stove.

A. rhodophyllum (rose-fronded).* *fronds* evergreen, triangular, tripinnate, elegantly spreading, about 1ft. long; pinnæ few, pinnate or bipinnate, the upper undivided ones 1½in. long, and, as well as the 1in. pinnules, rhomboid-trapezoid, and set on hair-like, black stalks; young fronds rosy-purple. *sori* at the apices of the lobes, but much broken up. 1884. A beautiful, stove hybrid.

habit, raised from spores of *A. Waltoni diffusum.* The pinnæ are long and deeply cut, after the manner of *A. cuneatum dissectum*, and the habit of the plant is dwarf and robust. 1894.

A. tenellum (tender). A pretty and delicate form, much resembling *A. gracillimum*, but with better-shaped fronds. 1894.

A. tenerum Bessonianum (Besson's). *fronds* having crowded, imbricating, kidney-shaped pinnæ. West Indies, 1896.

A. tetragonum (quadrangular). *sti.* slightly hairy, 1ft. or more in length. *fronds* pedato-tripinnate, 1ft. long, 1½ft. broad; terminal pinna spear-shaped, 6in. to 9in. long, 5in. to 6in. broad; pinnules deep green, spear-shaped, 2½in. to 3in. long, slightly lobed, rounded on their upper side, cuneate-truncate on their lower side at base. *sori* short, very narrow, disposed at the tips of the lobes down both sides. Brazil. Stove.

Adiantum—*continued.*

A. tetraphyllum acuminatum (taper-pointed). *fronds* pale green, tapering at the tip; pinnæ long, narrow-pointed. A particularly elegant variety.

A. t. gracile (slender). A handsome variety, of moderate stature, remarkable for the beautiful reddish tint assumed by the fronds when first developed.

A. t. obtusum (obtuse). *sti.* brown. *fronds* graceful, bipinnate, 8in. to 10in. long; pinnæ four to six; pinnules more rounded than in the type. 1889. (I. H. 1889, t. 86.)

A. trapeziforme. An illustration of this handsome West Indian species is given in Fig. 29.

FIG. 29. ADIANTUM TRAPEZIFORME.

A. Veitchii (Veitch's). A synonym of *A. monochlamys.*

A. versaillense (Versailles). A variety of *A. cuneatum.*

A. Victoriæ (Victoria's). *fronds* crowded, bipinnate, forming close, low tufts 4in. to 6in. high, rich green; pinnules rather large, bluntly conical or sub-rhomboidal. 1882. A handsome, dwarf, stove Maidenhair, "supposed to be a hybrid between *A. Ghiesbreghti* and *A. decorum* [*Wagneri*], but it appears more like a dwarf form of *A. tenerum Farleyense*" (Moore).

A. Wagneri (Wagner's). The correct name of *A. decorum.*

A. Waltoni (H. and E. H. Walton's). *sti.* 9in. long, glossy ebeneous. *fronds* nearly 1½ft. long, broadly ovate, erect, glabrous, evergreen, quadripinnate; pinnæ ascending, ovate, the lower ones long-stalked, the upper ones with the pinnules next the rachis elongated and compound; pinnulets pedicellate, more or less cuneiform, often somewhat oblique. *sori* abundant, four to six to a pinnule, placed in a sinus of the marginal lobes. 1887. Greenhouse hybrid.

A. W. diffusum (diffuse). An elegant and distinct form of *A. cuneatum*, having fronds much larger and better adapted for mixing with cut flowers. 1888.

A. Weigandii (Weigand's). *fronds* triangular, tripinnate, glabrous, about 1ft. long, forming a neat, tufted mass; pinnæ and pinnules long-stalked, the latter ovate from a broad base, lobed, with narrow sinuses. *sori* large, numerous, nearly circular, one or two on each lobe. America (garden origin), 1884. Greenhouse.

ADINA. This genus comprises about half-a-dozen species of stove trees or shrubs, natives of tropical and sub-tropical Asia and America. Flowers small or minute, in solitary or paniculate, globose heads. Leaves opposite, petiolate, ovate, lanceolate, or cordate.

A. globifera is the correct name of *Nauclea Adina.*

ADLUMIA. This genus belongs to the TRIBE *Fumarieæ* of ORD. *Papaveraceæ.*

ADONIS. Of this genus there are, according to Bentham and Hooker, about four species, broadly dispersed over the North temperate regions of the Old World (*A. autumnalis* is a native of Britain). To those described on p. 29, Vol. I., the following should be added:

A. amurensis (Amur River).* *fl.* golden-yellow, white, rose-coloured, or bright red, striped, 2in. across; petals twenty to fifty, rather longer than the sepals. February. *l.*, cauline ones (which are really two or three connate leaves) 3in. to 6in. long and broad, trisected to the base; segments crowded, pinnatisect to the base. Stem 8in. to 18in. high. Manchuria and Japan, 1895. Cool-house perennial. (B. M. 7490.)

ÆCHMANDRA. A synonym of **Kedrostis** (which *see*).

ÆCHMEA. Under this genus the following are included by J. G. Baker: *Androlepis, Canistrum* (kept distinct in Vol. I.), *Chevaliera* (also spelt *Chevalliera*), *Hohenbergia, Hoplophytum, Lamprococcus, Macrochordium, Pironneava,* and *Pothuava.* It now embraces about 130 species, natives of tropical America. The flowers are smaller than in *Billbergia,* and are very variable in colour. To the species described on p. 30, Vol. I., the following should be added:

Æ. amazonica (Amazon). A synonym of *Karatas amazonica.*

Æ. augusta (pleasing). *fl.* rosy-lilac, small, glomerulate; inflorescence paniculate. *l.* spreading, broad, ligulate, obtuse, denticulate, bright green, irregularly spotted with dull green. South Brazil, 1833. A large and robust species. SYNS. *Æ. ferruginea, Hohenbergia ferruginea* (R. H. 1831, p 437, f. 104).

Æ. aurantiaca (orange). The correct name of *Canistrum aurantiacum.*

Æ. aureo-rosea (golden-pink). *fl.*, petals reddish-yellow, in a rather loose, erect spike 3in. to 4in. long; peduncle 1ft. long, upper bract-leaves bright crimson. *l.* few, 1½ft. long, 1in. to 1¼in. broad. Brazil, 1863. Probably a variety of *Æ. nudicaulis.*

Æ. Barleei (Barlee's). *fl.* distichous; calyx with a globose, mealy tube; corolla pale yellow; lower bracts red, upper ones green; stem central, paniculately branched. *l.* eight or nine in a rosette, lorate-ensiform, green, 2ft. to 3ft. long, 2in. broad, thinly white-lepidote, prickly on the margins. British Honduras, 1883.

Æ. bracteata (bracteate). The correct name of the plant described on p. 213, Vol. I., as *Bromelia bracteata.*

Æ. brasiliensis (Brazilian). *fl.*, calyx, bracts, and rachis scarlet; petals blue, erect, emarginate-rounded at base; panicle contracted, oblong, 5in. long, highly glabrous, the branchlets sessile, short, two- to six-flowered. *l.* recurved-spreading, ligulate-linear, much dilated at base, rigid, channelled, the margins spiny-toothed, acuminate, 1½ft. to 3ft. long. Rio Janeiro, 1885. (R. G. 1202.)

Æ. bromeliæflora (Bromelia-flowered). *fl.* embedded in white, cottony tomentum; petals lemon-yellow, turning brownish-black; spike dense, 2in. to 6in. long; peduncle 1ft. to 2ft. long; bract-leaves bright red or pale greenish-white. *l.* twelve to twenty, rosulate, 2ft. to 3ft. long, 1½in. to 2in. broad, lorate from a large, ovate base. Trinidad, &c.

Æ. calyculata. SYNS. *Hohenbergia calyculata* (Ref. B. 236), *Hoplophytum calyculatum* (B. H. 1865, p. 162, t. 11), *Macrochordium luteum* (R. G. 1867, p. 164, t. 544).

Æ. Chantini (Chantin's). *fl.*, calyx and ovary reddish-yellow, ¾in. long; inflorescence a dense, ovoid, bipinnate panicle, 4in. to 6in. long; peduncle 1ft. long; upper bract-leaves bright red. *l.* ten to twelve in a utricular rosette, lorate, 1ft. long, 1½in. to 2in. broad, transversely zoned with green and white, cuspidate, minutely toothed. Amazon Valley, 1877. SYN. *Billbergia Chantini* (R. H. 1878, p. 112, f. 22; 1880, p. 272, f. 54-56).

Æ. cœlestis (F. d. S. 2146). SYNS. *Hohenbergia cœlestis* (Ref. B. 234), *Hoplophytum cœleste* (B. H. 1862, p. 97).

Æ. conspicuiarmata (conspicuously armed). *fl.* yellowish, fading to black, sessile, in a small, globose head; peduncle white-woolly, shorter than the leaves, with long, narrow bracts. *l.* long, recurved, and bent, spiny-toothed, dark, shining green above, densely white-punctate-striate beneath. Brazil, 1886. A fine Bromeliad. SYN. *Macrochordium macranthum* (R. G. 1886, p. 297, f. 34).

Æ. Cornui (Professor Cornu's). A form of *Æ. nudicaulis.*

Æ. crocophylla (Saffron-leaved). *fl.* green, small, in a dense, globose head 2½in. in diameter; peduncle erect, 6in. to 8in. long. *l.* about twenty in a rosette, lorate, 1½ft. to 2ft. long, 3in. broad, cuspidate, minutely serrated, the outer ones rose-coloured during the flowering period. Brazil, 1885. SYNS. *Ananas crocophylla, Chevaliera crocophylla.*

Æ. discolor (B. M. 4293; G. M. B. 1850, t. 121). This is a variety of *Æ. fulgens.*

Æ. Drakeana (Drake's).* *fl.*, calyx bright rose; corolla bright blue, 1½in. long; spike oblong, loose, 6in. long; peduncle 1½ft. long, violaceous at base, red above, white-tomentose. *l.* about twelve in a rosette, 1½ft. to 2ft. long, 2in. broad, channelled, mucronate, with distant spines. Ecuador, 1888. A fine species.

Æ. exsudans (sweating). SYN. *Bromelia exsudans* (B. H. 1879, p. 352, t. 18).

Æ. fasciata. SYNS. *Billbergia fasciata* (B. R. 1130), *B. rhodocyanea,* of Lemaire (B. M. 4383; F. d. S. 207).

Æ. Fernandæ (Fernanda's). The correct name of *Bromelia Fernandæ.* SYN. *Ananas Mensdorfianus.*

Æ. ferruginea (rusty). A synonym of *Æ. augusta.*

Æ. flexuosa (flexuous). A synonym of *Æ. spectabilis.*

Æ. Fuerstenbergii. The correct name of this plant is now *Streptocalyx Fuerstenbergii.*

Æchmea—*continued.*

Æ. Germinyana (Germiny's).* *fl.*, petals reddish-white, nearly twice as long as the sepals; spike dense, 6in. to 8in. long; peduncle half as long as the leaves; bracts bright red, the lower ones 1in. long. *l.* twenty to thirty, rosulate, lorate from an ovate base, 2ft. to 2½ft. long, 3in. broad, bending over from the middle. Colombia. SYNS. *Bromelia daguensis* (of gardens), *Chevaliera Germinyana* (R. H. 1881, p. 230).

Æ. gigantea (gigantic). *fl.*, petals reddish-blue, half as long again as the sepals; inflorescence a dense spike, 1½ft. to 2ft. long, 4in. to 5in. in diameter, at first globose, finally oblong; peduncle stout, erect, 2ft long; bract-leaves bright red, spreading. *l.* densely rosulate, ensiform, 6ft. to 8ft. long, 6in. to 8in. broad at base, firm, gradually tapering, with stout, black spines. South Brazil, 1888. SYN. *Chevaliera gigantea.*

Æ. Glaziovii (Glaziou's).* *fl.*, petals reddish-purple, half as long again as the sepals; inflorescence a dense, oblong panicle 4in. to 6in. long; peduncle 1ft. or more in length; bract-leaves imbricated. *l.* twenty in a rosette, lorate, generally 1½ft. long (but one plant at Kew had, according to J. G. Baker, leaves 7ft. to 8ft. long), horny, deltoid-cuspidate at apex. South Brazil, 1880. (B. H. 1881, p. 271, t. 13.)

Æ. glomerata (B. M. 5668). SYNS. *Hohenbergia erythrostachys* (R. H. 1869, p. 217, f. 53), *Pironneava Morreniana* (R. G. 805.)

Æ. Lalindei (Lalinde's).* *fl.*, calyx green, ellipsoid, pink at the tips; corolla not exserted; spike dense; bracts crimson, large, acute, reflexed; stem tall. *l.* 3ft. to 4ft. long, broad, concave, acute, denticulate, green. Colombia, 1883. A handsome plant. (I. H. n. s. 481.)

Æ. Legrelliana is a synonym of *Ortgiesia Legrellcana.*

Æ. Lindeni (B. M. 6565). SYN. *Hoplophytum Lindeni* (B. H. 1873, p. 81, t. 5).

Æ. lineata (lined). *l.* oblong-ligulate, concave, abruptly acuminate, finely and remotely toothed, green, with alternating broad stripes of white, disposed in cylindrical tufts, spreading at the apex; marginal spines black. Brazil, 1893. SYN. *Hoplophytum lineatum.*

Æ. macracantha (large-spined). A synonym of *Æ. Schiedeana.*

Æ. Mertensii (Mertens'). *fl.*, petals rose-pink, twice as long as the sepals; inflorescence a dense, cylindrical panicle 6in. to 9in. long; flower-bracts green, ½in. long; peduncle 1ft. to 1½ft. long; upper bract-leaves large, bright red. March. *l.* twelve to twenty in a utricular rosette, lanceolate, ovate at base, 2ft. long, 1½in. to 2in. broad, with small teeth. Dutch and British Guiana, 1830. (B. M. 3186.) SYN. *Hohenbergia Mertensii* (Ref. B. 284).

Æ. mexicana (Mexican). *fl.* on erecto-patent pedicels ½in. long; calyx green, ½in. long; petals bright crimson, connivent, protruding ½in. from the calyx; panicle oblong-cylindrical, 1ft. long, 4in. to 5in. broad, the lower branches 2in. to 3in. long; peduncle stout, 1ft. long; bracts colourless, erect. Winter. *l.* twenty to thirty in a dense rosette, lorate, with a deltoid-cuspidate tip, above 2ft. long, 3in. broad, the dilated base 4in. to 5in. broad, pale green, with darker green spots; prickles small, the lower ones tipped with brown. Mountains of Orizaba, 1886.

Æ. mucroniflora (having pointed flowers). *fl.*, petals bright yellow, cuspidate, ½in. long; inflorescence a dense, oblong spike 3in. to 4in. long; flower-bracts having a large cusp; peduncle less than 1ft. long, the upper leaves bright red. *l.* about a dozen in a rosette, lorate, 1ft. to 1½ft. long, 1½in. broad, firm, channelled, ovate at base, rounded to a cuspidate apex, with horny teeth. Demerara, 1855. (B. M. 4832.)

Æ. myriophylla (many-leaved). *fl.* distichous; calyx bright red; corolla pink, fading to lilac; scape 1½ft. high, panicled above, and, as well as the bracts, bright red. *l.* forming a dense rosette, narrow, channelled, attenuated, 2ft. to 2½ft. long, 1in. broad, dull green, sprinkled with silvery scales on the back, the margins armed with close, brown prickles. Tropical America, 1887. (B. M. 6939.)

Æ. nudicaulis (naked-stemmed). *fl.*, petals pale lemon-yellow; inflorescence a loose, drooping spike 3in. to 6in. long; peduncle 1½ft. to 2ft. long; bract-leaves bright red. *l.* about a dozen in a utricular rosette, lorate from an oblong base, 2ft. to 3ft. long, 2in. to 3in. broad, horny, with small prickles. Tropical America, 1825. SYNS. *Bromelia nudicaulis* (H. E. F. 143), *Pothuava nudicaulis* (R. G. 1096).

Æ. n. Cornui (Professor Cornu's). A form of the above, with a short, dense, oblong spike. Brazil, 1885. (R. H. 1885, p. 36, under name of *Æ. Cornui.*)

Æ. n. distans (distant). A variety having a loose flower-spike and short, broad leaves.

Æ. odora (odorous). *fl.* sessile, spreading; petals pale yellow; panicle loose, bipinnate, 1ft. to 1½ft. long; peduncle 1½ft. long; bract-leaves appressed. *l.* ten to twelve, 2ft. to 3ft. long, lorate, lepidote on both sides, but especially at the back. West Indies, 1879. A distinct but not very showy species.

Æ. Ortgiesii. This is now correctly known as *Ortgiesia tillandsioides.*

Æ. Pineliana (Pinel's). *fl.* in a dense, simple spike 2in. to 3in. long; sepals having a large cusp; petals bright yellow, ½in. long; peduncle 1ft. to 1½ft. long; bract-leaves bright red. *l.* twelve to fifteen in a utricular rosette, lorate, 1ft. to 1½ft. long, 1½in. broad, ovate at base, deltoid at apex, with brown-pointed spines. South Brazil, 1851. SYN. *Echinostachys Pineliana* (B. M. 5321).

Æ. purpurea (purple). *fl.* about 1in. long; bracts a dozen or more, bright red, 2in. to 3in. long; peduncle about 1ft. long; bract-leaves large, tinged with red. *l.* twelve to twenty in a utricular rosette, lanceolate, dilated at base, 2ft. long, 1½in. to 2in. broad, narrowed to the apex. South Brazil, 1831.

Æ. regularis (regular). *fl.* white; petals twice as long as the sepals; inflorescence a dense, oblong, bipinnate panicle 6in. to 8in. long, the lower branches subtended by large, red, lanceolate bracts; peduncle above 1ft. long; upper bract-leaves bright red. September. *l.* 1½ft. to 2ft. long, 1½in. to 2in. broad, lorate, horny, cuspidate, with a dilated, utricular base, and horny prickles ¼in. long. South Brazil, 1870.

Æ. rosea (rosy), of Baker. The correct name of *Canistrum roseum.* *fl.* white and green; inflorescence a dense head, 2in. to 3in. in diameter; peduncle erect; bract-leaves pink. *l.* about twenty in an open rosette, 1½ft. to 2ft. long, 1½in. to 2in. broad, mottled with darker green. South Brazil. (B. H. 1833, p. 195, tt. 14, 15, under name of *Canistrum roseum.*)

Æ. rosea (rosy), of gardens. A synonym of *Æ. suaveolens.*

Æ. Schiedeana (Schiede's). *fl.*, petals pale yellow, shortly protruded; inflorescence a tripinnate panicle 1½ft. long; lower branches subtended by large, red bracts; peduncle 2ft. long; upper bract-leaves bright red. *l.* about twenty in a rosette, lorate from an ovate base, 2ft. to 3ft. long, 2in. to 3in. broad, deltoid-cuspidate at tip, with large marginal teeth. Central Mexico, 1880. SYN. *Æ. macracantha.*

Æ. setigera (bristle-bearing). A garden synonym of *Billbergia pyramidalis Croyiana.*

Æ. Skinneri (Skinner's). *fl.* without bracts; petals yellow, shortly protruded; inflorescence an almost cylindrical panicle 1ft. long; peduncle erect, 1½ft. long; bract-leaves pale. March. *l.* about twenty in a utricular rosette, lanceolate, 2ft. to 2½ft. long, 2½in. to 3in. broad, ovate at base, with minute teeth. Guatemala, 1850. SYNS. *Androlepis Skinneri* (under which name it is briefly described in Vol. I.), *Billbergia Skinneri* (of gardens).

Æ. speciosa (showy). *l.* tufted, spreading, leathery, oblong, acute, mucronate, finely toothed, concave above, more or less densely covered with silvery scales, especially on the under-surface; upper surface bright shining green, with broad, longitudinal stripes of clear yellow. Brazil, 1893. A highly ornamental species, of moderate size. SYN. *Lamprococcus speciosus.*

Æ. spectabilis (showy).* *fl.* distant, sessile, erecto-patent; calyx pale pink, ½in. to ⅝in. long; petals bright red, lingulate, shortly protruded; panicle ovate, bipinnate, 1½ft. to 2ft. long, 6in. to 8in. in diameter, the lower branches 3in. to 4in. long; peduncle erect, stout, 1½ft. long; bracts pale, erect. Winter. *l.* twenty to thirty in a dense rosette 3ft. to 4ft. in circumference, lanceolate from a dilated base, bright green, horny, 3in. broad, channelled, with scattered, whitish spots. Guatemala, 1886. Plant stemless. SYN. *Æ. flexuosa* (R. H. 1876, p. 311).

Æ. suaveolens (sweetly-scented). *fl.*, sepals mucronate; petals reddish-purple, ½in. long; inflorescence an oblong, bipinnate panicle 6in. to 8in. long; bracts mucronate; peduncle slender, 1½ft. long; bract-leaves inconspicuous. April. *l.* few, in a long, utricular rosette, the outer ones linear, the inner ones lanceolate, 1½ft. to 2ft. long, 1in. to 1½in. broad, horny, with ascending prickles. Brazil, 1831. SYNS. *Æ. rosea* (of gardens), *Billbergia purpureo-rosea* (B. M. 3304).

Æ. tillandsioides (Tillandsia-like). *fl.*, petals twice as long as the sepals; panicle 4in. to 5in. long, consisting of four to eight sessile spikes; peduncle 1ft. long; upper bracts bright red, serrated. *l.* about a dozen in a utricular rosette, lanceolate, 1ft. to 1½ft. long, 1½in. broad, gradually narrowed, horny. Amazon Valley, &c., 1881. This must not be confounded with *Ortgiesia tillandsioides.*

Æ. Veitchii (B. M. 6329). SYN. *Chevaliera Veitchii* (B. H. 1878, p. 177, t. 5; R. H. 1880, p. 450).

Æ. viridis (green). The correct name of *Canistrum viride* (B. H. 1874, p. 376, t. 16).

Æ. Weilbachii (Weilbach's).* *fl.*, sepals bright lilac; petals lilac at first, but turning brownish-black; ovary bright red; inflorescence a loose, bipinnate panicle 4in. to 6in. long, with a bright rachis; peduncle 1ft. to 1½ft. long, dull red. *l.* twelve to thirty in a rosette, bright green on both sides, lorate, 1ft. to 1½ft. long, 1½in. broad, pliable, ovate at base, cuspidate at apex, with minute teeth. South Brazil, &c., 1854. SYN. *Lamprococcus Weilbachii* (B. H. 1861, p. 305; B. M. 6435; R. G. 539).

Æ. W. leodiensis (Weilbach's, Liége).* *fl.* violet-rose, changing to dark red; bracts scarlet, mixed with violet and green; scape shorter than the leaves. *l.* about forty in a rosette, the basal half armed with larger and more crowded spines than in the type, the upper surface dark olive and bright green, the basal part beneath washed violet-brown and spotted blood-red. Brazil, 1887.

ÆCIDIUM. Formerly these fungi, which belong to the *Uredineæ*, or Rusts, were accorded generic rank; but now they are believed to be but a subordinate stage

Æcidium—*continued.*

in a very complex life-cycle of such genera as *Uromyces* and *Puccinia*. This, however, has not been proved in regard to all the reputed species of this form-genus. An excellent example of this Æcidium-form is to be found in the Barberry Rust (*Æ. berberidis*), which is seen upon the common Barberry and other species in spring, as well as upon the allied genus *Mahonia*, in the form of bright orange-yellow spots on the leaf-blades, stalks, as well as less frequently upon the flowers and the berries. Later they give rise to the purple, brown, and, finally, almost black spots on Wheat and other cereals, and known by the name of *Puccinia graminis*. Nearly a hundred years ago the fungologists of the time thought there was a connection between the two, but it is only within comparatively recent years that the life-cycle has been worked out by the late Professor De Bary. This destructive fungus is not restricted to Wheat and other cereals, but is also found on several species of ornamental and other grasses; hence the specific name (*graminis*). Both uredospores, or summer-spores, and teleutospores exist, the former being differentiated from the latter by being one-celled instead of two-celled. The summer-spores are the means by which the area of infection is spread, and the teleutospores (or final spores), those by which the fungus is tided over the winter, to develop again as soon as the conditions are favourable in the spring. The grain and straw are both rendered useless by this fungus, which is difficult to cope with, as even if there are no Barberries or Mahonias in the vicinity of the Wheat the rust-fungus has been proved to exist.

Other Æcidium-forms occur in species of *Abies*; one, *elatinum*, being very destructive, and responsible for the extraordinary malformations found upon Silver Firs, known as Witches' Brooms. The needles of such infested trees are sickly-looking, and only last one season. Sometimes, too, the extraordinary branch growths proceed from a large, gouty swelling. Yet other species affecting Firs are *Æ. pseudocolumnare*, in the needles of several species of *Abies*, notably on *A. pectinata*; and *Æ. strobilinum* on cones of Spruce. For further information upon Pine Fungi, *see* **Pinus.**

ÆGERIA TIPULIFORMIS. This is an old name for the Currant Clearwing Moth (*Sesia tipuliformis*).

ÆGICERAS. SYN. *Melaspinæa.* This genus is monotypic. The correct name of *Æ. fragrans* is *Æ. majus.*

ÆGILOPS (of Linnæus). A synonym of **Triticum** (which *see*).

ÆGINETIA. A synonym of **Bouvardia** (which *see*).

ÆGIPHILA. SYNS. *Manabea, Omphalococca.* This genus embraces about thirty species, natives of tropical America, from Brazil to the West Indies and Mexico.

Æ. grandiflora. The correct name is *Clerodendron grandiflorum.*

ÆGLE. Golden Apple. This genus embraces two or three species of spiny, stove trees, natives of tropical India, Java, and tropical Western Africa. Flowers white, hermaphrodite, rather large; calyx small, four- or five-toothed; petals four or five, oblong-lanceolate, spreading, imbricated; panicles axillary, few-flowered. Berries large, very hard, with edible pulp. Leaves trifoliolate; leaflets slightly crenulate, pellucid-dotted, membranous. *Æ. Marmelos* is known in India as the Bael-tree.

Æ. sepiaria (hedge-loving). The correct name of *Citrus trifoliata.* SYN. *C. triptera.*

ÆGOCHLOA. Included under **Gilia** (which *see*).

ÆONIA (name not explained by author). Also spelt *Œonia.* ORD. *Orchideæ.* A small genus (four or five species) of stove Orchids, natives of Madagascar, and closely allied to *Angræcum.* Flowers racemose, shortly pedicellate; sepals and petals sub-equal, free; lip sessile at the base of the column, produced into a spur at base;

Æonia—*continued.*

column very short; peduncles lateral, simple. Leaves distichous, coriaceous. Stems not pseudo-bulbous. The following species is the only one calling for mention here. For culture, *see* **Angræcum.**

Æ. polystachya (many-spiked). *fl.* like those of a small Brassavola, but spurred; sepals and petals whitish or greenish; base of the lip green; racemes numerous. *l.* ligulate, bilobed. 1889. SYNS. *Angræcum Kimballianum, A. polystachyum.*

ÆONIUM. Included under **Sempervivum** (which *see*).

AËRANTHUS. This genus embraces about three species. Flowers often solitary, rather large, pedicellate; sepals erecto-patent, free; petals similar to the dorsal sepal, but smaller; lip produced into a spur-like process; column very short. Leaves distichous. To the species described on p. 31, Vol. I., the following should be added. *See also* **Mystacidium,** and for culture *see* **Angræcum** (to which this genus is allied).

A. brachycentron (short-spurred). This scarcely differs from *A. grandiflorus.*

A. Grandidierianus (Grandidier's). A synonym of *Angræcum Grandidierianum.*

A. Leonis (Leon Humblot's). A synonym of *Angræcum Humblotii.*

A. ophioplectron (snake-spurred). A synonym of *Angræcum ophioplectron.*

A. trichoplectron (hair-spurred). *fl.* white, solitary, axillary; sepals lanceolate, acute; petals linear, acute; lip broad, nearly conchoid at base, acuminate at top; spur long, filiform; peduncle one-flowered. February. *l.* 5in. long, ¼in. wide, soft, linear, bidentate at apex. Madagascar.

AERIAL. Growing in the air. Aerial Roots are those that appear above the ground.

AËRIDES. These lovely plants are best grown under stove or hot-house treatment. They require a liberal amount of moisture both at the roots and in the atmosphere, during the growing season. Under cooler conditions, while the plants are at rest, only sufficient moisture is needed to maintain the foliage in a plump condition. Though usually classed as suitable for pot-culture, many *Aërides* are dwarf-growing, and possessing a compact habit they are better adapted for baskets, in which they may be easily suspended near the roof-glass. The most suitable kinds for this purpose are *A. affine, A. crassifolium, A. Lobbii,* and the *A. maculosum* section. If these are removed to the brighter, cooler, and drier conditions of the intermediate house during the resting season beneficial results will be derived; this especially applies to *A. crassifolium,* which is usually a somewhat shy flowerer. Under the above conditions this difficulty is overcome. To the species described on pp. 31-3, Vol. I., the following should be added:

A. ampullaceum (flask-like). A synonym of *Saccolabium rubrum.*

A. Augustianum (Auguste Linden's).* *fl.* light rose-colour, 1in. to 1¼in. long; lip three-lobed, the side lobes falcate, rounded or nearly truncate above, the front lobe much longer, with crenulate margins, slightly bilobed at apex; racemes arching. *l.* 6in. to 7in. long, 1¼in. broad, dark green, bilobed at apex. Philippine Islands, 1890. (G. C. 1890, f. 36; L., t. 210.)

A. Ballantinianum (Ballantine's). A variety of *A. suavissimum.*

A. Bernhardianum (Bernhard's). *fl.*, side lobes of the lip overlapping each other, the front lobe covering both in front; raceme having the appearance of that of *A. quinquevulnerum. l.* narrow, strap-shaped. Borneo, 1885. A distinct and fine species.

A. Brookeii (F. d. S. 151; P. M. B. ix., t. 145) is identical with *A. crispum.*

A. Burbidgei splendens (Burbidge's splendid). *fl.* rich purple; side lobes of the lip ochre, spotted with brown; tip of the spur ochre. 1885.

A. cornutum (horned). A variety of *A. odoratum.*

A. Ellisii (Ellis'). A variety of *A. virens.*

A. Emericii (Emeric Berkeley's). *fl.* pale pink, with darker tips to the perianth segments and purple mid-lobe of the lip, numerous, ½in. in diameter; perianth segments short, incurved, with rounded tips; lip funnel-shaped, passing into the stout,

Aërides—*continued.*

incurved spur; raceme axillary, 5in. to 6in. long, shortly pedunculate. May. *l.* distichous, nearly 1ft. long, 1in. to 1½in. broad, linear, coriaceous, deeply bifid at apex. Andaman Islands, 1832. (B. M. 6723.)

FIG. 30. FLOWERS OF AËRIDES FIELDINGII.

A. expansum (expanded). A synonym of *A. crassifolium.*

A. falcatum compactum (compact). A variety differing from the type principally in its shorter inflorescence, shorter and broader leaves and thicker and stronger stems.

A. f. Houlletianum. The correct name of *A. Houlletianum.* (R. X. O. iii., t. 204.)

A. f. Leoniæ (Mrs. Leonie Allan Goss'). *fl.*, side laciniæ blunt, retuse, even dolabriform. 1882. (W. O. A. vii., t. 328, under name of *A. expansum Leoniæ.*)

A. Fieldingii alba (white). *fl.* snow-white, closely disposed on the spikes. 1883. A lovely variety. (L. 1896, t. 538.) Flowers of the typical plant are shown in Fig. 30.

A. flavidum (yellowish). A synonym of *A. suavissimum.*

A. formosum (beautiful). *fl.* white, spotted, disposed in graceful, pendent spikes; lip trifid, beautifully coloured with amethyst. 1832. A handsome plant, supposed to have been bred between *A falcatum* and *A. odoratum.*

FIG. 31. PORTION OF RACEME OF AËRIDES LAWRENCEÆ.

A. Godefroyanum (Godefroy's). A variety of *A. multiflorum.*

A. Hughii (Hugh Low's). *fl.* well formed, about ten to a spike; sepals pale rose with darker shading; petals pale rose, with darker spots; lip bright rose and purple. *l.* about 6in. long. 1894.

A. Huttoni (Hutton's). A name used in gardens for both *A. Thibautianum* and *Saccolabium Huttoni.*

A. Iansoni (I'Anson's). Probably a natural hybrid between *A. expansum* and *A. odoratum.* Birma, 1890.

A. illustre (lustrous). A form of *A. maculosum.*

Aërides—*continued.*

A. Lawrenceæ (Lady Lawrence's).* *fl.* nearly as large as those of *A. crispum;* sepals and petals white, changing to yellowish-tipped rosy-purple; lip having its side lobes high, oblong-dolabriform, its central lobe tipped rosy-purple, two purple lines running back to the mouth of the spur, which is conical, acute, entire; racemes 2ft. long, bearing upwards of thirty flowers. Tropical Asia, 1832. See Fig. 31. (Gn. 1839, t. 702; W. O. A. vi. 270.)

A. L. Amesianum (Ames's). *fl.* of a rich, pale orange-yellow, larger than in the type, borne on stalks over 2ft. in length; sepals and petals tipped with purple; racemes very long. Malay Archipelago. (R. X. O. iii., p. 252.)

A. L. Sanderianum (Sander's).* *fl.* 1½in. across; sepals and petals creamy-white, tipped magenta, recurved at the margin; lip large, the upper half of the side lobes yellow, frilled at the edges, the middle lobe obovate, folded, magenta; spur greenish-yellow at the end; racemes long. *l.* broad, short, retusely bilobed. Eastern tropical Asia, 1884.

A. Leeanum (W. Lee's). *fl.* sweet-scented, less than 1in. long; sepals and petals rose-purple, white at base; lip small, three-lobed, deep purple, with a green-tipped spur; racemes short and dense. Winter. *l.* 7in. to 9in. long, 1½in. broad. Origin unknown. Allied to *A. quinquevulnerum.*

A. lepidum (charming). *fl.* white, as large as those of *A. affine;* sepals and petals tipped with purple; lip having the projected anterior part purple; spur cylindrical, curved; racemes ascending, many-flowered. *l.* lorate, obtusely bilobed. India. A pretty species.

A. Lindleyanum (Lindley's). A variety of *A. crispum.*

A. Lobbii is now regarded as a form of *A. multiflorum.*

A. L. Ainsworthii (Ainsworth's). *fl.* brighter-coloured than in the type; spikes about 2ft. long. Moulmein. A fine variety.

A. maculosum formosum (beautiful). *fl.* large and numerous; sepals and petals white, marked with numerous rose-purple spots; lip white at base, marked on the crests and auricles with rose-purple lines, the large, elliptic front lobe entirely rose-purple. 1885. A fine form.

A. m. illustre (lustrous). A robust form, having large flowers blotched with purple and tipped with amethyst, and fewer and shorter leaves.

A. margaritaceum (pearly). *fl.* pure white, produced in spikes. Summer. *l.* spotted. India. A pretty species, something in the way of *A. maculosum.*

A. marginatum (margined). *fl.* densely packed on the rachis; sepals and petals pale yellow, the anterior border purple; side lobes of lip semi-oblong, deep orange, the central one oblong-ligulate, toothleted, yellow, changing to sepia-brown; spur light green, conical; racemes drooping. *l.* rather broad; lorate, bilobed or emarginate, keeled on the under-side. Philippine Islands, 1885. Probably a variety of *A. quinquevulnerum.*

A. McMorlandi (McMorland's). *fl.* white, spotted with peach-colour, freely produced in long, branched racemes. June and July. *l.* bright green, nearly 1ft. long. India. A fine but rare species.

A. multiflorum (many-flowered). The correct name of *A. affine* (B. M. 4049; W. S. O. i. 21). *A. Lobbii* (I. H. 1868, t. 569) and *A. roseum* (P. F. G. ii., t. 60; R. G. viii., t. 267) are regarded by Hooker as synonyms or forms of this species.

A. m. Godefroyanum (Godefroy's). *fl.* light rosy-white, streaked and spotted with amethyst on the sepals and petals, comparable with those of *A. maculosum;* lip triangular, with a retrorse, hooked, solid tooth, and a very small, angular spur, the disk rich amethyst. Cochin China, 1886.

A. m. Veitchii (Veitch's).* *fl.* white, dotted with soft rose-pink; racemes long, drooping, branched. June and July. *l.* 8in. long, dark green, spotted. (B. H. 1881, 8-9.)

A. nobile (W. S. O. ser. i., t. 11; R. G., t. 641) is identical with *A. suavissimum.*

A. odoratum birmanicum (Birma). *fl.* smaller than in the type; lateral sepals having a light purple line outside; middle lacinia of the lip purple, very narrow, with a few teeth at the margin; side laciniæ apicular. 1837.

A. o. Demidoffi (Demidoff's). *fl.* white, large, forming a rich spike; tips of the sepals, petals, and lip marked with purple; spur spotted with purple, and tipped with green. 1885. (L., t. 14.)

A. Ortgiesianum (Ortgies'). *fl.*, sepals and petals blotched and warted with purple; side segments of the lip purple, the middle one white, blunt, bilobed, not serrated, the spur green, all dotted and barred red. 1885. This looks like a small *A. quinquevulnerum*

A. pachyphyllum (thick-leaved). *fl.* resembling those of *A. Thibautianum,* few in a short raceme; sepals and petals light crimson-lake, nearly as large as in that species, oblong-ligulate; laciniæ of the lip small, painted with more or less warm purple; spur prominent, and, as well as the column, white. *l.* very fleshy, short. Birma, 1830.

A. paniculatum (panicled). A synonym of *Sarcanthus paniculatus.*

A. Picotianum (Picot's). A synonym of *A. falcatum Houlletianum.*

Aërides—*continued.*

A. platychilum (flat-lipped). *fl.* 1in. across; sepals and petals of a light buff colour; lip yellow and purple, flat, with a reflexed spur; scape 5in. long. *l.* 6in. long, more than 1in. broad. Habitat unknown. 1893. This is closely allied to *A. falcatum Houlletianum.*

A. quinquevulnerum Schadenbergianum (Schadenberg's). A variety of more compact habit, having shorter and broader leaves than the type. 1836. A portion of the inflorescence of the typical species is shown in Fig. 32.

A. radicosum (rooting). *fl.* ⅜in. across; sepals and petals light rose-purple, spotted with deep purple, the lateral sepals largest; lip three-lobed, the mid-lobe deep rose-purple; spur horn-like compressed; pedicels pale rose-purple; peduncles racemose, rarely branched. *l.* 7in. to 10in. long, ⅜in. to 1¼in. broad. Southern India. SYN. *A. rubrum* (of gardens).

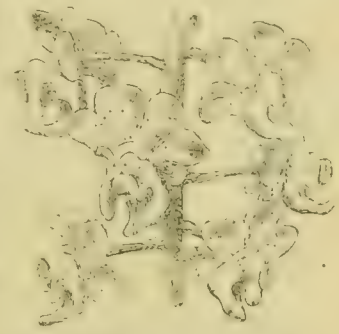

FIG. 32. PORTION OF RACEME OF AËRIDES QUINQUEVULNERUM.

A. Reichenbachii (R. X. O. ii., t. 104) is synonymous with *A. suavissimum* (P. F. G. ii., t. 66).

A. R. cochinchinense (Cochin China). *fl.*, inflorescence denser than in the type; yellow of the lip much deeper. Cochin China. A grand variety.

A. Roebelenii (Roebelen's). *fl.* very fragrant, the size of those of *A. quinquevulnerum*; sepals and petals greenish-white, tipped with white; petals often minutely toothed; lip rosy, with yellow, oblong side lobes lacerated on the upper edge, as is also the much longer, oblong, curved middle lobe; spur short, conical; racemes erect, 1ft. long, about twenty-five-flowered. Philippine Islands, 1884. Probably a variety of *A. quinquevulnerum.*

A. Rohanianum (Prince Camille de Rohan's). A synonym of *A. suavissimum.*

FIG. 33. PORTION OF RACEME OF AËRIDES VIRENS ELLISII.

A. rubrum (red) of gardens. A popular name for *A. radicosum.*

A. Sanderianum (Sander's). A variety of *A. Lawrenceæ.*

A. Savageanum (Savage's). *fl.* less than 1in. across; sepals and petals white stained with crimson-purple in the lower half, the upper half crimson-purple; lip deep crimson-purple, with erect side lobes, a small, incurved middle lobe, and a greenish straight spur; racemes as long as the leaves. *l.* 7in. to 9in. long, 1in. to 1¼in. broad. Origin unknown. (R. ii., t. 81.)

A. Schrœderi (Baron Schrœder's). A form of *A. maculosum.*

A. suavissimum aurantiacum (orange). A much handsomer plant than the type, more robust in growth, and having a deep, rich, orange-yellow lip. Borneo, 1866.

A. s. Ballantinianum (Ballantine's). *fl.* variable; dorsal sepal and petals somewhat toothed; lateral

Aërides—*continued.*

sepals white, with a purple eye-blotch at the top; lip white, with orange or self-coloured side lobes, or marked with purple streaks and transverse bars. A fine variety.

A. s. B. aureum (golden). *fl.* large, sweetly-scented; sepals and petals white, tinged with pink or pale purple; lip having a few tiny dots of brown. 1893. A handsome variety.

A. s. maculatum (spotted). *fl.* delightfully fragrant; sepals and petals white, profusely spotted with pink, as is also the lip.

A. Thibautianum (Thibaut's). *fl.*, sepals and petals rose-coloured; lip bright amethyst; raceme very long, with the flowers rather openly set upon it. Java. Allied to *A. quinquevulnerum.*

A. Vandarum is the correct name of *A. cylindricum* (B. M. 4932).

A. Veitchii (Veitch's). A variety of *A. multiflorum.*

A. virens Dayanum (Day's). A fine variety, with very long racemes. India.

A. v. Ellisii. A portion of the inflorescence of this grand variety is shown in Fig. 33.

A. v. grandiflorum (large-flowered). *fl.* white, spotted with pink, larger and more gracefully disposed than in the type. April and May. India.

A. v. superbum (superb). *fl.* brighter, and spikes longer, than those of the type. India.

A. Warneri (Warner's). A variety of *A. crispum.*

A. Wightianum (Wight's). A synonym of *Vanda parviflora.*

A. Williamsii (W. S. O. ser. i., t. 21) is a form of *A. Fieldingii* (B. H. 1876, t. 18-19; W. O. A. vii., t. 309).

A. Wilsonianum (Wilson's). *fl.*, sepals and petals pure white; lip lemon-yellow. A distinct, dwarf species, in appearance much resembling *A. odoratum.*

ÆRUA (from *Eroua*, the Arabic name). ORD. *Amarantaceæ.* A genus embracing about ten species of stove herbs or under-shrubs, inhabiting the warmer regions of Africa and Asia. Flowers white or brownish, small or minute, in solitary or paniculate spikes. Leaves alternate, opposite, or somewhat whorled. Two of the species have been introduced, but they are probably lost to cultivation.

ÆRUGINOSE. Light bluish-green—the colour of verdigris.

ÆSCHYNANTHUS. About forty species are included in this genus; they are found in the East Indies, the Malayan Archipelago, and Eastern tropical Asia, extending as far as China. To those described on p. 33, Vol. I., the following should be added:

Æ. bracteata (bracteate). *fl.*, calyx lobes red, ⅜in. long; corolla scarlet, 1¼in. long, nearly glabrous outside, the lower lip with reflexed lobes; peduncles 1in. long, one- to seven-flowered; bracts scarlet, 1in. long. April. *l.* elliptic, acuminate, fleshy, 4in. long, cuneate or rounded at base. Branches terete. Temperate Himalayas, 1839. Plant epiphytic. SYN. *Æ. Paxtoni* (J. H. S. iv., p. 79).

Æ. grandiflora parasitica (parasitic). *fl.*, calyx and corolla rather large, and leaves narrower, than in the type, the calyx lobes slightly longer than the tube. (B. iv., t. 167, under name of *Æ. parasitica*; B. R. 1841, t. 49, under name of *Æ. grandiflora*).

Æ. Hildebrandii (Hildebrand's). *fl.* orange-scarlet, few, from the upper leaf-axils, the segments margined with deep red, 1in. long, glandular, pubescent, the tube curved. *l.* rather crowded, opposite and alternate, 1in. long, somewhat fleshy, ovate, narrowed to a very short petiole. Stem creeping; branches 2in. to 4in. high. Birma, 1894. (B. M. 7365.)

Æ. Horsfieldii (Horsfield's). *fl.* pale scarlet; calyx segments linear-lanceolate. August. *l.* ovate-lanceolate, somewhat acuminate. *h.* 2ft. Java, 1842. Plant glabrous. (R. G. 297.)

Æ. maculata (spotted). This is hardly distinguishable from *Æ. ramosissima* except by the small calyx. (B. R. 1841, t. 28.)

Æ. marmoratus (marbled). *fl.* axillary; corolla with a curved, green tube, and an oblique limb of roundish, ciliated segments blotched with chocolate-brown. *l.* oblong-lanceolate, obovate-lanceolate, or ovate, acuminate, scarcely toothed, obscurely veined, reddish-purple below, 3½in. long. Origin unknown, 1882.

Æ. obconica (obconical). *fl.* blood red, in pairs on a very short peduncle; calyx broadly campanulate, nearly 1in. across, with a recurved margin; corolla short, often having yellow lobes banded with red. July. *l.* 2in. to 2½in. long, 1½in. broad, orbicular-ovate, obtuse or slightly acute, fleshy; petioles ⅛in. long. Stem slender, elongated. Malayan Peninsula and Islands, 1825. (B. M. 7336.)

Æ. parasitica (parasitic). A form of *Æ. grandiflora.*

Æschynanthus—*continued.*

Æ. Paxtoni (Paxton's). A synonym of *Æ. bracteata.*

Æ. purpurascens (purplish). *fl.* green; calyx segments dark purple, as long as the corolla. March. *l.* oblong-lanceolate, acuminate, fleshy, sinuate-toothed. Java, 1845. More curious than beautiful. (B. M. 4236.)

Æ. ramosissima (much-branched). *fl.* scarlet; sepals free or united half-way; corolla 1in. long, scarcely contracted. *l.* 4in. long, 1¾in. broad. Sub-tropical Himalayas, 1837. This scarcely differs from *Æ. grandiflora parasitica.* (P. M. B. vi., p. 195.)

ÆSCULARIA ANISOPTERYX. *See* **March Moth.**

ÆSCULUS. Syn. *Hippocastanum.* This genus includes about fourteen species of trees and shrubs, natives of North America and the mountains of Colombia, Mexico, the Himalayas, Persia, and the Malayan Peninsula. Flowers white, red, or pale yellow, polygamous, irregular, disposed in terminal, thyrsoid racemes or panicles; calyx campanulate or tubular, five-cleft; petals four or five, unequal, clawed, imbricated; stamens five to eight, free. Capsules coriaceous, smooth or prickly, three-lobed or sub-globose, three-celled, or by abortion one- or two-celled. Leaves opposite, without stipules, digitately five- to nine-foliolate; leaflets serrated. To the species described on p. 34, Vol. I., the following should be added. *See also* **Pavia** (which is included under this genus by modern botanists).

Æ. californica (Californian). A synonym of *Pavia californica.*

Æ. chinensis (Chinese). *fl.* rather small, disposed in a panicle. *l.* distinctly stalked, oblong-oblanceolate, finely serrated. China, 1889. Syn. *Æ. sinensis.*

Æ. chinensis, of gardens. A synonym of *Æ. turbinata.*

Æ. glabra. There is a double-flowered form of this (*flore-pleno*).

Æ. Hippocastanum has now been definitely proved to be a native of the mountains of Greece.

Æ. macrostachya (large-spiked). A synonym of *Pavia alba.*

Æ. parviflora (small-flowered). A synonym of *Pavia alba.*

Æ. Pavia (Pavia). A synonym of *Pavia rubra.*

Æ. Plantierensis (Plantier's). A garden hybrid between *Æ. Hippocastanum* and *Æ. rubicunda.* 1894.

Æ. rubicunda Watsoniana (Watson's). A variety having darker flowers and shorter stamens than in the type.

Æ. sinensis (Chinese). A synonym of *Æ. chinensis.*

Æ. turbinata (top-shaped). *fl.* white. *fr.* globose-turbinate, without spines; seeds about two in each fruit. Japan, 1838. This tree closely resembles *Æ. Hippocastanum* in general appearance, but is readily distinguishable by its leaves being of a pale greyish colour beneath. Syn. *Æ. chinensis,* of gardens.

Æ. Watsoniana (Watson's). A form of *Æ. rubicunda.*

ÆTHEILEMA. A synonym of **Phaylopsis** (which *see*).

ÆTHIONEMA. About sixteen species, natives of the mountains of Southern Europe, Asia Minor, and Persia, are included in this genus. Flowers pink or purple, small, without bracts, on slender pedicels.

There is no better subject for the rock-garden than *Æ. grandiflorum,* once it is established. It is, however, a true sun-lover, and if a little lime be mixed with the soil in the particular nooks in which it is grown, a fine mass of pink blossom will be produced in summer. Its prostrate habit lends itself well to rockery decoration.

ÆTHONIA. Included under **Tolpis** (which *see*).

AFRICAN CORN LILY. A name applied to Ixias.

AFRICAN CYPRESS. *See* **Widdringtonia.**

AFRICAN HEMP. *See* **Sparmannia africana.**

AFRICAN TOAD-FLOWER. *See* **Stapelia.**

AFZELIA. This genus embraces about ten species of unarmed, stove trees, natives of tropical Africa and Asia. Flowers rather large, racemose; calyx segments four, imbricated; petal clawed, orbicular or reniform, the lower rudimentary ones small or wanting; stamens three to eight, free; racemes crowded in panicles at the tips of the branches. Pods obliquely oblong, compressed. Leaves abruptly pinnate or rarely almost imparipinnate; leaflets in few pairs, coriaceous. *A. africana* is the best-known species.

AGALLOCHUM. A synonym of **Aquilaria** (which *see*).

AGALLOSTACHYS. A synonym of **Bromelia** (which *see*).

AGALMA VITIENSIS. *See* **Heptapleurum vitiense.**

AGALMYLA. Syn. *Orithalia.* This is a monotypic genus, *A. longistyla* being merely a long-styled form of the true species, *A. staminea.*

AGANISIA. Syn. *Koellensteinia.* The half-dozen species of this genus are confined to tropical America. To those described on p. 35, Vol. I., the following should be added:

A. cærulea. The correct name is *Acacallis cyanea.*

A. cyanea (blue). *fl.* rather small, in a short, erect raceme; sepals and petals white, ovate, acute; lip blue, roundish-cuneate, undulated at the tip; scapes slender. June. *l.* evergreen, forming a close, upright tuft, broadly lanceolate, strongly ribbed. Columbia. Syn. *Warrea cyanea* (B. R. 1845, 28).

A. c. alba (white). *fl.* pure white. 1885.

A. lepida (scaly). *fl.* pure white, about 1½in. across, very handsome, disposed in tall, many-flowered spikes. *l.* erect, Grass-like. Brazil, 1893. A well-marked species. (L. 400; R. X. O. 1865.)

A. tricolor (three-coloured). *fl.* closely resembling those of *A. cyanea,* but the sepals are whitish on both sides, the petals are light blue, and the callus of the saddle-shaped, orange-brown lip is different in shape. Amazons, 1886. A fine Orchid.

AGANOSMA. This is regarded by Bentham and Hooker as synonymous with **Ichnocarpus** (which *see*).

AGAPANTHUS. Syns. *Abumon, Mauhlia.* According to Baker ("Flora Capensis," vol. iii.) this genus is monotypic. To the varieties described on p. 36, Vol. I., the following should be added:

A. umbellatus atrocæruleus (dark blue). *fl.* of a beautiful dark violet.

A. u. giganteus (gigantic). A very robust form, with a very large umbel of 150 to 200 dark blue flowers, and leaves 2in. broad. *h.* 3ft. to 4ft. 1879.

A. u. pallidus (pale). *fl.* a pale porcelain-blue.

A. u. Saundersonianus (Saunderson's). *fl.* darker than in the type.

AGAPETES. This genus includes about twenty-five species, natives of India, the Malayan Peninsula, and Fiji. To those described on p. 36, Vol. I., the following should be added:

A. macrantha (large-flowered). *fl.* white, yellow, and red; corolla 1¾in. long, ¼in. to ⅜in. broad. December. *l.* shortly petiolate, lanceolate, narrowed at both ends. Khasia, Moulmein, &c., 1849. This closely resembles *A. variegata,* but has much larger flowers. Syn. *Thibaudia macrantha* (B. M. 4566).

A. Mannii (Mann's). *fl.* white, ¼in. long, with a cylindrical corolla. *l.* lanceolate. Branches almost glabrous. Otherwise like *A. obovata.* Northern India, 1892. Greenhouse.

A. obovata (obovate). *fl.* reddish-brown, solitary, about ¼in. long, borne on stalks scarcely as long as the leaves. *l.* coriaceous, obovate, about ¼in. long. Branchlets scurfy and thickly leafy. Northern India, 1892. A dwarf, densely-branched, not very ornamental, greenhouse shrub.

A. pulcherrima (very pretty). A synonym of *A. variegata,* with which *Thibaudia pulcherrima* (B. M. 4303) and *T. variegata* are also identical.

AGARICUS. To this genus belong several very destructive and common fungi met with upon various conifers and other subjects, as well as upon orchard trees. The best known is *A. melleus (Armillaria mellea),* or Honey Agaric, an edible fungus found in late summer upon trees of many kinds, but particularly upon Spruce, Pines, Larch, Beech, and less often upon Plum. This species, fully dealt with under **Pine Fungi,** is responsible for the condition known as Tree-Root Rot. Not so well known as the Honey Agaric is *A. adiposus (Pholiota adiposa),* a species with bright yellow slimy cap, covered with reddish-brown scales; the gills are yellow, changing to reddish-yellow, and the reddish pileus scales extend on to the stem. Like *A. melleus,* it grows in clusters; but, unlike that species, it is not edible. This is found much later than *A. melleus,* and on both living and dead

Agaricus—*continued.*

wood. Firs, again, are the principal host-plants, and the wood of stems so attacked breaks up in a remarkable manner as the fungus spreads, and usually takes on an unhealthy, yellowish-brown colour. Trees subject to canker are frequently attacked by this species, whose sporospores may be found growing out of the wounds caused by the canker-fungus. Besides being of a bright yellow, the cap, as well as the stem, is covered with darkish scales. See **Pine Fungi** and **Honey Agaric** for remedies.

AGARISTA (a name of mythological origin, after the beautiful daughter of Clisthenes; in allusion to the beauty of the flowers). SYN. *Amechania.* ORD. *Ericaceæ.* A genus embracing about twenty-two species of greenhouse, glabrous or pubescent, usually evergreen shrubs, natives of Brazil, New Granada, Peru, and Mexico. Flowers white, pink, red, or purple, in axillary and terminal racemes; calyx free, five-lobed or parted; corolla conico-tubular or urceolate, with five recurved teeth; stamens ten, included; filaments shortly adherent. Leaves alternate, hard, coriaceous, reticulate-veined. The two species here described thrive in a compost of peat and sand. Cuttings, not too young, will strike in sand, under a hand-glass, in moderate heat. *See also* **Agauria.**

A. neriifolia (Nerium-leaved). *fl.* crimson, urceolate, tubular, secund, drooping, disposed in a terminal, racemose panicle. June. *l.* petiolate, oblong-lanceolate, acute, 3in. long, 1in. broad, ovate at base, coriaceous, entire, pale beneath. *h.* 2ft. Brazil, 1849. Plant highly glabrous. SYNS. *Andromeda neriifolia, Leucothoe neriifolia* (B. M. 4593).

A. pulchra (pretty). *fl.* greenish-white, in axillary and terminal racemes. May. *l.* petiolate, ovate, mucronate, coriaceous, entire. Branchlets obtusely angular. *h.* 2ft. Brazil, 1846. SYNS. *Andromeda pulchra, Leucothoe pulchra* (B. M. 4314).

AGARISTA (of De Candolle). Included under **Coreopsis** (which *see*).

AGATHÆA. Blue Marguerite; Cape Aster. Bentham and Hooker refer this genus to *Felicia*, but the correct name of *A. cœlestis* is *Aster rotundifolius.*

A. amelloides (Amellus-like). A synonym of *A. cœlestis* (*rotundifolius*).

AGATHELPIS (from *agathos*, pleasant, and *thelpis*, hope; reason for name not obvious). ORD. *Selagineæ.* A small genus (less than half-a-dozen species) of greenhouse shrubs or under-shrubs, natives of South Africa. Calyx limb shortly five-cleft; corolla spreading, star-like; stamens two, affixed above the middle of the tube; spikes usually slender, elongated. Leaves scattered, linear or small. *A. angustifolia* and *A. parvifolia* have been introduced, but it is doubtful if they are still in cultivation.

AGATHIS. According to the authors of the "Genera Plantarum," this is the correct name of **Dammara** (which *see*).

AGATHOMERIS. A synonym of **Humea** (which *see*).

AGATHOPHYLLUM. This is now regarded as a synonym of **Ravensara** (which *see*).

AGATHOSMA. As many as a hundred species are included in this large genus.

A. acuminata is a variety of *A. imbricata.*

A. bruniades is a variety of *A. cuspidata* (the type is not in cultivation).

A. villosa (villous). *fl.* flesh-coloured, lilac, or white. *h.* 1ft. or more. This is probably identical with *Diosma Wendlandi.*

AGATHOTES. A synonym of **Swertia** (which *see*).

AGATI. This is now included, by Bentham and Hooker, under *Sesbania, A. coccinea* being regarded as a form of **S. grandiflora** (which *see*).

AGAURIA (name not explained by author). SYNS. *Agarista* and *Leucothoe* (in part). ORD. *Ericaceæ.* A small genus (four species) of greenhouse, evergreen, highly glabrous or glandular-pubescent shrubs or small trees, natives of tropical Africa, Madagascar, and Mauritius. Flowers generally white, in axillary and terminal racemes; calyx free, five- or six-cleft or parted; corolla cylindrical with five recurved teeth; stamens ten to twelve, included. Leaves almost opposite and alternate, oblong or lanceolate, entire, pale beneath. For culture of the two species described, *see* **Andromeda.**

Agauria—*continued.*

A. buxifolia (Box-leaved). *fl.* pink, in terminal racemes; pedicels somewhat secund. Summer. *l.* very shortly petiolate, coriaceous, highly glabrous, broadly ovate or nearly oblong, mucronate, somewhat cordate at base, glaucous and at length almost ferruginous beneath. *h.* 1ft. Mauritius, 1822. Greenhouse. SYN. *Andromeda buxifolia* (B. M. 2640; L. B. C. 1494).

A. salicifolia (Willow-leaved). *fl.* purplish-violet or (in cultivation) whitish; corolla oval-oblong; pedicels spreading-recurved, somewhat secund. June. *l.* petiolate, narrow-lanceolate, acuminate at both ends, entire, green above, woolly beneath. *h.* 4ft. Mauritius, 1825. Hardy. SYN. *Andromeda salicifolia* (B. M. 3286; H. E. F. iii., t. 192).

AGAVE. Including *Littæa.* According to J. G. Baker's monograph of the *Amaryllideæ*, this genus embraces nearly 140 species, natives of tropical America, and especially plentiful in the Southern United States. Flowers greenish-yellow; perianth tube short, the segments almost equal, oblanceolate, falcate; stamens inserted at or below the throat of the tube; filaments filiform, usually much longer than the segments; inflorescence densely sub-spicate or a thyrsoid panicle; peduncle having only reduced leaves. Fruit an oblong capsule, loculidally three-valved. Leaves densely rosulate, more or less fleshy and usually firm in texture, with a pungent spine at the tip and numerous horny prickles on the margins. The great majority of Agaves are *monocarpic, i.e.*, only fruiting once. Several *polycarpic* species have been noted at Kew, and it is worthy of mention that all these belong to the sub-genus *Littæa*, in which the flowers are borne in pairs, forming a dense sub-spicate inflorescence. So far as is known at present, none of the sub-genus *Euagave*, of which the common *A. americana* may be taken as the type, are polycarpic, but die after flowering.

To the species and varieties described on pp. 38-42, Vol. I., the following should be added:

A. albicans (B. M. 7023). This is scarcely more than a variety of *A. micracantha.* There is a form with variegated leaves.

A. Alibertii (Alibert's). *fl.* 1in. long, on short pedicels; perianth tube greenish, funnel-shaped, the segments short, lanceolate-deltoid; peduncle (including the lax, simple raceme) 4ft. to 5ft. high. *l.*, produced ones ten to twelve, lanceolate, denticulate, forming a rosette. Probably Mexico, 1877. SYN. *Alibertia intermedia.*

A. angustissima (very narrow). *fl.* yellow, with purple stamens, borne in pairs, 1½in. long, very narrow; peduncle 12ft. high. *l.* 12in. to 20in. long, ¼in. broad, flat on both sides, the margins filiferous, the apex pungent. Mexico, 1893. Allied to *A. filifera.* (G. and F. 1893, vi., p. 5, f. 1.)

A. atrovirens is the correct name of *A. Salmiana.*

A. attenuata (R. H. 1875, p. 149, f. 31, 32). SYNS. *A. glaucescens* (B. M. 5333; G. C. 1887, ii., p. 219, f. 55), *A. spectabilis*, of gardens.

A. Baxteri (Baxter's). *fl.* disposed in a thyrsoid, loose panicle 4ft. to 5ft. long; perianth tube yellow, ¼in. long, dilated at the middle; filaments ⅜in. to 1in. long; anthers linear, ¼in. long; ovary cylindrical-trigonous, 1in. long; peduncle 4ft. to 5ft. long before the flowers appear. March. *l.* about thirty in a dense, sessile rosette, oblanceolate, about 1ft. long, and 3in. across at the widest part, the tip pungent, brown, shortly decurrent, the marginal spines spreading, hooked, deltoid-cuspidate, brown, about ⅛in. long. Mexico (?).

A. Beauleuriana (Beauleur's). A synonym of *A. Theometel.*

A. Bouchei (Bouche's). *fl.* greenish-yellow, 1½in. long, including the ovary; spike dense, 2ft. long. *l.* thirty or forty in a dense rosette, oblong-lanceolate, rather fleshy, 1½ft. to 2ft. long, 3in. to 4in. broad, ½in. thick, with very small, reddish-brown teeth. Caudex short, cylindrical. Mexico, 1861. (B. M. 7558.)

A. bracteosa (bracted). *fl.* in pairs, forming a dense spike; perianth segments about ½in. long, the ovary slightly longer; stamens about 2in. long; stem 3ft. high, the flowerless part densely covered with spreading or recurved bracts 5in. to 6in. long. *l.* ten to fifteen, broadly linear-attenuate, 1½ft. to 1¾ft. long, 1½in. broad at base, the margins minutely serrulated. Monterey, Mexico, 1883. (G. C. 1892, ii., p. 776, f. 138, 139.)

A. Celsiana. There is a small variety of this, having leaves only 8in. to 9in. long.

A. Fenzliana differs from *Hookeri* in its smaller prickles.

A. Franzosini (Francesco Franzosini's). *fl.* green and yellow, borne in a huge, candelabrum-like panicle, on a stout peduncle

Agave—*continued.*

40ft. long. *l.* thirty or forty in a rosette, oblong-spathulate, persistently glaucous, 8ft. to 9ft. long, 1ft. broad, very rigid, with a very pungent end-spine decurrent for about 6in., and distant, dull brown, hooked or straight teeth. 1892. Plant stemless. (G. C. 1892, xii., p. 179, f. 31.)

A. geminiflora (twin-flowered). *fl.* greenish-brown, 1½in. to 2in. long; tube ¼in. long; peduncle 18ft. to 24ft. long, including the dense spike. *l.* 200 to 300 in a dense rosette, recurved, linear, 1½ft. to 2ft. long, ¼in. to ½in. broad, bright green, convex on both sides, the pale edge splitting off into fine threads, the tip slightly pungent. Mexico, 1797. Stemless. (B. R. 1145.) SYNS. *Bonapartea juncea* (of gardens), *Littæa geminiflora.*

A. Ghiesbreghtii is identical with *A. pruinosa.*

A. glaucescens (bluish-grey). A synonym of *A. attenuata.*

A. Haseloffii (Haseloff's). *fl.* green, 1½in. long; tube short; segments ¼in. long; peduncle 7ft. long, including the dense spike (2ft.). *l.* about twenty in a rosette, lanceolate, 1½in. to 2in. long, 3in. broad, the end-spine brown, ¼in. long, the marginal teeth close and brown. Probably Mexico. Plant shortly caulescent. (B. M. 7527.)

A. Henriquesii (Henriques'). *fl.*, perianth segments tinged dark brown, lanceolate, 1in. long; style purplish-brown; panicle spike-like; peduncle, including the inflorescence, 12ft. to 14ft. long. *l.* in a dense rosette, oblong-lanceolate, bright green, margined with dark brown, 2ft. long, 5in. broad, narrowed to the base and to the pungent apex, armed with spreading prickles. Mexico (?), 1887. (G. C. 1887, i., p. 732, f. 70.) SYN. *Littæa Henriquesii.*

A. heteracantha (variable-spined). A garden synonym of *A. multilineata.*

A. Hystrix (Hystrix). A synonym of *A. striata.*

A. Ixtli (native name) and **A. ixtlioides** (Ixtli-like). These are synonymous with *A. rigida.*

A. Jacquiniana (Jacquin's). A variety of *A. lurida.*

A. kewensis (Kew). *fl.* unknown. *l.* thirty to forty in a rosette, oblanceolate-oblong, 3½ft. to 4ft. long, 7in. to 8in. broad, bright green, the somewhat pungent end-spine short and brown, the face concave in the middle, the marginal prickles small, close and brown. Mexico. Plant shortly caulescent. (B. M. 7532.)

A. laxifolia (lax-leaved). *fl.* green, about 2in. long, including the ovary; stamens 2in. long; anthers very large, linear; panicle lax, 4ft. to 5ft. long; peduncle the same length. *l.* twenty to thirty in a lax rosette, oblong-lanceolate, firm, 1½ft. to 2ft. long, with copious very small marginal spines and a pungent one at the apex. Mexico. Plant shortly caulescent. (B. M. 7477.)

A. Leopoldii II. (Leopold II.'s). *l.* succulent, very numerous, narrow, deep green, acutely pointed, the thin shreds on the margin pure white and curiously curled. 1893. A garden seedling.

A. lurida (lurid). *fl.* greenish-yellow, 3in. long, the tube ½in. long; stamens twice as long as the segments; peduncle 12ft. to 16ft. long, including the thyrsoid panicle (3ft. to 6ft.). June. *l.* thirty to forty in a rosette, oblanceolate, 2ft. to 3ft. long, 2½in. to 3½in. broad, very glaucous, the pungent end-spine 1in. long, the small, rather distant prickles reddish-brown, changing to black. Mexico, 1731. Plant nearly or quite stemless. (B. M. 1522; Ref. B. 307.)

A. l. Jacquiniana (Jacquin's). *fl.* small. *l.* 2½ft. to 3ft. long. Trunk 1ft. to 1½ft. long. 1848. (B. H. ix., t. 25, and B. M. 5097, under name of *A. Jacquiniana.*)

A. maculata (spotted). *fl.* purplish-green, 1½in. long, in a lax, somewhat spicate raceme 6in. to 12in. long; peduncle 1½ft. to 3ft. long, the bract-leaves few and much reduced. *l.* twelve to twenty in a rosette, lanceolate, spreading, 6in. to 12in. long, ¾in. to 1in. broad, glaucous-green, with irregular brown blotches on both sides, the point not pungent, the edges serrulated. Texas, 1856. Stemless. SYN. *A. maculosa* (B. M. 5122; G. C. 1872, p. 1194, f. 273).

A. maculosa (spotted). A synonym of *A. maculata.*

A. Maximowicziana (Maximowicz'). *fl.* green, sessile, borne in pairs, disposed in a cylindrical spike; peduncle, including the spike, 6ft. to 7ft. high. *l.* in a dense rosette, obovate-lanceolate, 3½in. broad, densely and irregularly toothed, the terminal spine sometimes forked. 1889. Allied to *A. densiflora.*

A. mexicana (Mexican). *fl.* greenish-yellow, 2½in. to 3in. long; peduncle 18ft. long, including the thyrsoid panicle (7ft. to 8ft.). *l.* twenty to thirty in a rosette, oblanceolate-spathulate, 2ft. to 3ft. long, 5in. to 6in. broad, very glaucous, the brown, pungent point 1in. long, the prickles rather distant, ¼in. to ½in. long. Mexico. Stemless. A common plant in European gardens. (G. C. 1883, i., f. 22.)

A. mitis (mild). *fl.* about 2in. long, the segments about as long as the tube; peduncle 9ft. to 10ft. long, including the dense spike (3ft. to 4ft.). *l.* about thirty in a rosette, oblanceolate, 1ft. to 1½ft. long, 3in. broad, bright green, flat in the middle, the end-spine weak, the crowded teeth very small. Mexico, 1860. Shortly caulescent. (G. C. 1877, ii., p. 717, f. 137.) SYN. *Littæa mitis.*

Agave—*continued.*

A. Morrisii (Morris'). *fl.*, perianth bright yellow, 2in. to 2½in. long; stamens nearly twice as long as the segments; panicle thyrsoid, the main branches 1½ft. long; peduncle, including the inflorescence, 15ft. to 20ft. long. *l.* twenty or more in a dense rosette, oblanceolate-spathulate, 6ft. to 7ft. long, nearly 1ft. broad, gradually narrowed to the pungent-spiny apex, dull green, the margins prickly. Jamaica, 1887. (G. C. 1887, i., p. 643, f. 105.)

A. multilineata (much-lined). *fl.* 1½in. long; tube very short; spike slender, not dense, finally 5ft. long; peduncle 3ft. long. Autumn. *l.* thirty to forty in a dense rosette, ensiform, 1ft. long, 1in. broad, gradually narrowed to a pungent apex, with a narrow grey edge, small irregular teeth, rounded on the back, with copious darker green lines. Probably Mexico. Stemless. SYN. *A. heteracantha* (of gardens).

A. Nickelsi (Nickels'). This is described as a new species, resembling *A. Victoriæ Reginæ.* 1895.

A. Poselgerii is identical with *A. heteracantha.*

A. pubescens (downy). *fl.* greenish, 1½in. long; tube longer than the segments; spike 6in. long, loosely twelve- to fifteen-flowered; peduncle 3ft. long. *l.* twelve to fifteen in a rosette, spreading, lanceolate, 9in. to 12in. long, 1in. to 1½in. broad, papillose and minutely pubescent all over, dull green, spotted with purple towards the base, not serrulated. Mexico, 1870. (R. G. 1873, p. 227, t. [illegible].)

A. regia (royal). *fl.* unknown. *l.* twelve to fifteen in a rosette, oblong-spathulate, 1½ft. to 1¾ft. long, 4in. to 5in. broad, bright green on the flat face, the somewhat pungent brown tip ¼in. long, the prickles moderately close, very small, brown, the upper ones ascending, the lower ones deflexed. Probably Mexico. (G. C. 1877, ii., p. 620, f. 124). SYN. *A. revoluta* (of gardens).

A. revoluta (revolute). A garden synonym of *A. regia.*

A. rigida (rigid). *fl.* greenish, 1½in. to 2in. long, the tube very short; stamens twice as long as the segments; peduncle, including the thyrsoid panicle, 12ft. to 15ft. long. *l.* thirty to forty in a rosette, ensiform, 1½ft. to 2ft. long, 1½in. to 2in. broad, rigidly erecto-patent, glaucous, the end-spine 1in. long, the teeth small, brown or nearly black. South Mexico. Plant nearly or quite stemless, yielding a valuable fibre. SYNS. *A. Ixtli, A. ixtlioides* (B. M. 5395).

A. Salmiana (R. H. 1873, p. 373, tt. 40, 41; G. C. 1871, ii., p. 141, t. 31; 1877, ii., f. 33). The correct name is *A. atrovirens.*

A. Schottii (Schott's). *fl.* bright yellow, 2in. long; panicle lax, somewhat spicate, 1ft. long; peduncle and pedicels very short; scape 4ft. to 5ft. long. *l.* forming a dense, sessile rosette, linear from an ovate base, 1ft. long, pungent at apex, the edges breaking up into fibres. Arizona. (B. M. 7567.)

A. spectabilis (remarkable). A garden synonym of *A. attenuata.*

A. striata (B. M. 4950). SYN. *A. Hystrix;* also known in gardens as *Dasylirion junceum* and *Yucca Hystrix.*

A. Taylori (Taylor's). A garden hybrid between *A. geminiflora* and probably *A. filamentosa* ("not *A. densiflora*"—Baker).

A. Terraccianoi (Dr. Terracciano's). *fl.* greenish-yellow, sessile, solitary or in pairs in the axils of the bracts; inflorescence about 5ft. high. *l.* many in a rosette, narrow-lanceolate, about 1ft. long, 2in. broad, deep green, speckled with blood-red. Probably Mexico or Texas, 1895. (R. G. 1895, p. 66, f. 14.)

A. Theometel (native name). *fl.* yellowish-green, 3in. long; stamens twice as long as the segments; peduncle 10ft. to 12ft. long, including the thyrsoid panicle. *l.* about thirty, oblong-spathulate, 1½ft. to 2ft. long, 4½in. to 5in. broad, nearly flat on the face, green, the dark brown end-spine 1in. long, the distant prickles ¼in. long. Mexico. Stemless. SYN. *A. Beauleuriana.*

A. univittata variegata (variegated). *l.* deep bronzy green, margined with white, and having a band of bright green running down their centre. 1893. A handsome seedling.

A. Villarum (Villa Brothers'). *l.* quite spineless, as in *A. filifera,* but much longer, more spreading, and less dense. 1886. An Italian hybrid between *A. filifera* and *A. zylonacantha,* the former being the seed-bearer.

A. vivipara. This name is also applied in gardens to *A. sobolifera* (G. C. 1877, ii., f. 150).

A. weissenburgensis (Weissenburg). *fl.* erect, tubular, 1½in. long, disposed in clusters along the side of a long flower-stalk, which, with the panicle, measures 7ft. to 8ft. *l.* thirty to forty, 8in. to 9in. long, 2½in. broad, upwards of ¼in. thick, oblong-lanceolate, mucronate, with remote, spiny teeth on the margins. Probably Mexico, 1885.

AGENORA. Included under **Hypochæris** (which *see*).

AGERATUM. SYN. *Carelia* (of Adanson). Bentham and Hooker include here *Cœlestina,* which has been described on p. 356, Vol. I. This genus embraces about sixteen species of herbs and shrubs, natives of tropical or sub-tropical America, one being broadly distributed over the warmer regions of the globe.

Ageratum—*continued.*

Few bedding-plants are superior to Ageratums alike as regards their freedom of colour of flowers, and the time over which their beauty extends. Frequently they are the last of the summer occupants of beds and borders to succumb to frost; while they are most useful in providing cut-flower material throughout the season. Where it is not desired to utilise them as bedding-plants they may be effectively employed as edgings—the Imperial Dwarf Azure and the Imperial Dwarf Blush White being very suitable on account of their compactness of habit—a quality which is wanting in some few of the garden varieties.

To the species described on p. 42, Vol. I., the following should be added:

A. corymbosum (corymbose). The correct name of *Cœlestina ageratoides.*

A. strictum (erect). A synonym of *Adenostemma viscosum.*

A. Wendlandi (Wendland's). *fl.* blue, with rosy reflections, produced in abundance. *l.* cordate, dark green. Stems hairy. Mexico, 1885. A dwarf, compact species.

AGLÆA. A synonym of **Melasphærula** (which *see*).

AGLAONEMA. About a score species—all tropical—are included here. Spadix sessile or stipitate; spathe straight, at length marcescent; peduncles fascicled. Leaves ovate- or oblong-lanceolate. To the species described on p. 42, Vol. I., the following should be added:

A. acutispathum (acute-spathed). *fl.*, spadix sessile, 1¾in. long; spathe light green, 3¼in. long, 1¼in. broad, ovate-lanceolate, acuminate, widely expanded; scape as long as the petioles. *l.* 6in. to 8in. long, 2½in. to 3½in. broad, elliptic-ovate, acuminate, slightly oblique, rounded and slightly cuneate at base, the apex gradually attenuated into a fine point 1in. long; petioles 3in. to 4½in. long, sheathing. Hong Kong (?), 1885. Nearly hardy.

A. angustifolium (narrow-leaved). *fl.*, spathe whitish, 1½in. long, ellipsoid; spadix, including the stalk, 1½in. long. *l.* 5in. to 9½in. long, ½in. broad, elongated-linear-oblong, acuminate, cuneate-rounded at base, the margins undulated; petioles 1½in. to 2in. long. Stem ¼in. thick, erect, shining. Penang, 1895.

A. costatum (ribbed). *fl.*, spathe light green, 1in. long; spadix very large, protruding. *l.* 4in. to 5in. long, 2½in. to 3in. broad, ovate, acute or cuspidate, retuse or somewhat cordate at base, dark green, spotted and veined with white; midrib stout. Perak, 1892.

A. Curtisii (Curtis's). A variety of *A. oblongifolium.*

A. Hookerianum (Hooker's). *fl.*, spathe dark green, cymbiform, 1½in. to 2in. long, oblong, cuspidate. *l.* 8in. to 11in. long, 3½in. to 4½in. broad, elliptic-ovate or elliptic-oblong, acuminate. Stem elongated, ½in. thick. Khasia Hills, 1874.

A. integrifolium (entire-leaved). A synonym of *A. oblongifolium.*

A. Lavallei (Lavalle's). A synonym of *Schismatoglottis Lavallei.*

A. nebulosum (clouded). *l.* 5in. to 8in. long, 1in. to 1½in. broad, oblong or obovate-oblong, obliquely cuspidate-acuminate at apex, obtuse at base, green, irregularly marked with greenish-white above; petioles 1½in. to 2in. long, channelled above, sheathed. Java, 1887. (I. H. ser. v. 24).

A. nitidum (shining). A synonym of *A. oblongifolium.*

A. oblongifolium (oblong-leaved). *fl.*, spathe green, margined with white, 2in. to 4in. long, cuspidate; spadix stout, nearly as long as the spathe; peduncle 4in. to 8in. long. *l.* 8in. to 2ft. long, 2in. to 4in. broad, linear-oblong, acuminate, acute at base, dark green, shining; petioles 4in. to 6in. long. Stem 1ft. to 3ft. high. Penang, &c. SYNS. *A. integrifolium, A. nitidum.*

A. o. Curtisii (Curtis's). *l.* variegated with white along the principal lateral veins. Penang, 1897.

A. pictum compactum (compact). *fl.* spathe green, pointed, the outer surface shining. *l.* short, oblong-ovate, acuminate, unequal-sided, dark sap-green, sparingly blotched grey; petioles sheathing, green, with a membranous, whitish margin. Stems very short, erect. Java, 1883. There is another variety, *gracile.*

A. pumilum (dwarf). *fl.*, spathe ⅜in. long. *l.* 3in. to 4½in. long, ovate or ovate-lanceolate, acuminate, rounded at base, deep sea-green, marbled and blotched with white; petioles shorter than the blades. Caudex rooting. Birma, 1894.

A. rotundum (round). *fl.*, spathe green, hooded, 2½in. long. *l.* roundish-ovate, 5in. long, dark green tinged with pink above, purple beneath. Stems short. Malaya (?), 1893. (J. H. xxvii., p. 379, f. 56.)

A. versicolor (variously coloured). *l.* ovate, green in two shades, with white patches. East Indies, 1893. The genus of this plant is uncertain.

AGNUS-CASTUS. *See* **Vitex Agnus-castus.**

AGONIOPTERIS. *See* **Acrostichum.**

AGONIS (from *agon*, a gathering, a collection; in allusion to the number of the seeds). SYN. *Billiottia* (of Brown). ORD. *Myrtaceæ.* A genus comprising ten species of greenhouse, evergreen shrubs or small trees, natives of West Australia. Flowers rather small, sessile, in dense, globose, axillary or terminal heads; calyx segments five, often scariose; petals five, spreading; stamens free, sometimes ten, opposite and alternate with the petals, sometimes twenty or more; bracts imbricating, often involucrate. Leaves alternate, often crowded on the branchlets, small or narrow and coriaceous, entire. *A. flexuosa* and *A. marginata* are rare in this country, but are grown at Kew. They should be firmly potted in a compost of turfy loam and peat, with a liberal addition of sand. Water must be frequently given during the growing season, but more sparingly during winter. In autumn the plants may be placed in a sheltered and sunny position, to ripen their wood and induce the formation of buds. In the South of England these plants may prove hardy. Propagation may be effected by cuttings of the half-ripened shoots, inserted in sandy peat, under a bell glass.

A. flexuosa (flexible). *fl.-heads* white, axillary, surrounded by broad bracts, which, with the numerous long, white stamens, are the most attractive features of the inflorescence. Summer. *l.* lanceolate, like those of the Willow, smooth, dark green, the margins tinged with purple. *h.* (in Australia) 40ft.; may be limited to the size of a small pot shrub. (Gn. xxix. 534.)

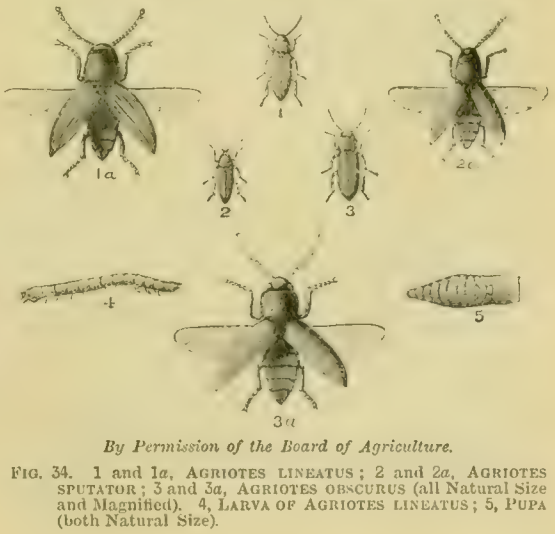
A. marginata (margined). *fl.-heads* white, axillary and terminal, about twenty-flowered; petals small; stamens long, hair-like. Summer. *l.* coriaceous, slightly hairy, in other respects like those of the common Box. Branches twiggy, numerous, the youngest ones silky-hairy. SYN. *Fabricia stricta.* (L. B. C. 1219.)

AGOSERIS. A synonym of **Troximon** (which *see*).

AGRICOLÆA. A synonym of **Clerodendron** (which *see*).

AGRILUS. ORD. *Coleoptera.* Out of some 500 known species only five are found in Britain. They usually inhabit the stems of young Beech; but one species, a most beautiful insect, is credited with inflicting damage upon Roses. It is, however, such a rare insect that the likelihood of a severe attack is very remote.

AGRIOTES. ORD. *Coleoptera.* To this genus belong several most destructive species in the garden, as their larvæ, together with those of a few others, are popularly known as "Wireworms." The worst offenders are *A. sputator*, ⅓in.; *A. obscurus*, ⅓in.; and *A. lineatus*, ⅓in. The female beetles deposit their eggs, which are of a dirty white, either in the soil close to the food-plants on which they have elected the larvæ when hatched



By Permission of the Board of Agriculture.

FIG. 34. 1 and 1*a*, AGRIOTES LINEATUS; 2 and 2*a*, AGRIOTES SPUTATOR; 3 and 3*a*, AGRIOTES OBSCURUS (all Natural Size and Magnified). 4, LARVA OF AGRIOTES LINEATUS; 5, PUPA (both Natural Size).

Agriotes—*continued.*

shall feed, or else in the plants themselves, towards the base. The larvæ live a long time as grubs, three to even five years. Finally, they become yellowish-white pupæ in cells of soil. See Fig. 34. *See* **Wireworms.**

AGRIPHYLLUM. A synonym of **Berkheya** (which *see*).

AGROPYRUM. A genus of Grasses, comprising one or two British species. *See* **Triticum.**

AGROSTEMMA. Bentham and Hooker include this genus under **Lychnis** (which *see*), the specific names remaining unchanged. To the species described on p. 43, Vol. I., the following should be added:

A. Walkeri (Walker's). *fl.* richly coloured, compact, and very freely produced. 1890. A garden hybrid between *A. coronaria* and *A. flos-Jovis.*

AGROSTICULA. A synonym of **Sporobolus** (which *see*).

AGROSTIS. Syn. *Vilfa* (of Adanson). Nearly a hundred species are embraced in this genus; they are broadly dispersed over the globe, but are mostly found in North temperate regions. *See also* **Sporobolus.**

A. algeriensis (Algiers). A garden synonym of *Aira capillaris.*
A. capillaris (hair-like), of gardens. A synonym of *A. nebulosa.*
A. capillaris, of Thore. A synonym of *A. elegans.*
A. Spica-venti. The correct name is *Apera Spica-venti.*

AGROTIS. A very large genus of moths, several of whose Caterpillars are amongst the most destructive of garden insects. The chief depredators, however, are *A. segetum*, or Turnip Moth, and *A. exclamationis*, the Heart and Dart Moth. In this country the larvæ are amongst those popularly known as Surface Caterpillars, because of their habit of feeding just beneath the surface of the soil. In America some near allies are known as Cutworms, and are, if anything, more destructive than their English relatives. The latter popular name is a very appropriate one, and is in allusion to the insects' habits of severing the stems of their food-plants. All the members of the family seem practically omnivorous, and by reason of their very accommodating tastes they are most objectionable visitors to flower-gardens, market-gardens, and agricultural lands. The Moths are on the wing in summer, and the eggs are deposited on the leaves of the plants on which they have elected to feed, but close to the ground. As stated in Vol. III., the larvæ of the two species are very difficult to distinguish. The chief point of distinction, however, lies, according to Buckler, in the fact that in *A. exclamationis* the black spiracles are always larger than the spots before and behind them; while upon each of the first five segments there is a pear-shaped blotch which is rather darker than the body-colour. Again, if carefully examined, it will be seen that the larvæ of *A. exclamationis* are darker than those of the other species.

Less destructive than the two species already noted are *A. suffusa* (*A. ypsilon*) and *A. nigricans.* In America the former is a great pest in certain seasons, the Cabbage and Tomato crops being the chief sufferers. Here it chiefly lives upon such coarse weeds as Plaintain, Cow Parsley, and the like; but like its congener already named it is not very fastidious in its tastes. In wing expanse it is about 1½in., blackish as to fore-wings, relieved by a slight tinge of red, with blackish spots and dots; the hind-wings are greyish-white. The larva is brown, with a paler stripe at the sides; it feeds from April to June, the perfect insect appearing in July and August. *A. suffusa* is a slightly larger insect, having brown and yellowish fore-wings, with black outlined spots and other black markings; the hind-wings are greyish. The larva is yellowish-brown, with light greenish sides, and feeds from May to July.

Turnips, swedes, and mangels are often badly attacked; and, less often, celery, potatoes, carrots, beet, cabbage, radishes, and lettuce; while the roots of corn and grass are

Agrotis—*continued.*

also laid under contribution by these pests. Auriculas, Polyanthuses, Asters, and herbaceous plants generally are frequently quite spoilt by the caterpillars, though the insects actually responsible for the mischief seldom get the credit.

Soot which has not been exposed has been found of great benefit for dusting round infested plants. Kainit has also been successfully employed. The object of the cultivator should be to get the plants to grow quickly; and this may be done by the judicious employment of artificial manures suitable to the particular crop. Nitrate of soda is most useful in the case of mangels. The hoe should be frequently employed, as this stirring of the soil exposes the larvæ (which, as a rule, feed some 2in. or 3in. beneath the soil) or their pupæ to the eyes of insectivorous birds, some of the most useful of which are the much-abused rook and its relative the starling, partridges, and plovers. In the case of gardens the use of an illuminated Moth trap (as employed by collectors) might be tried with success on summer evenings, as the Moths are readily attracted by light. If this trap were set early in the summer, doubtless many females would be captured before they had a chance of depositing their eggs. A powerful lamp, such as an electric or acetylene, would be equally useful. The time at which each species is found upon the wing would have to be taken into account, as *A. segetum* and *A. exclamationis* are earlier Moths than the other two mentioned. See also **Surface Caterpillars** and **Turnip Fly.** The Moths are seldom seen in the daytime, as they are so well protected by their colouring.

AGYLOPHORA. A synonym of **Uncaria** (which *see*).

AILANTHUS [not *Ailantus*]. Four species of somewhat fœtid, tall trees, natives of India, China, and Australia, are included in this genus. Flowers small, polygamous, on bracteolate pedicels; calyx short, five-lobed; petals five, spreading; disk ten-lobed, panicles terminal, branched. Samaræ rather large. Leaves alternate, imparipinnate; leaflets alternate.

A. erythrocarpa (red-fruited). A form of *A. glandulosa*, with fruits more brightly coloured than usual.
A. flavescens (yellowish). A synonym of *Cedrela sinensis.*

AIPHANES. A synonym of **Martinezia** (which *see*).

AIRA. Syn. *Fussia.* Four or five species, all European, are included in this genus. To those described on p. 44, Vol. I., the following should be added. Several plants formerly placed hereunder are now referred to **Deschampsia** (which *see*).

A. capillaris (thread-like). This plant possesses all the general characters of *A. pulchella*, but is of larger proportions, attaining a height of 1½ft. under cultivation; the branches of the panicle being long, irregular, and divaricate. It is very useful in the making-up of bouquets. Provence, &c. Syns. *A. provincialis* (R. H. 1892, f. 21), *Agrostis algeriensis* (of gardens).
A. provincialis (Provence). A synonym of *A. capillaris.*

AIZOON. Ord. *Ficoideæ.* This genus embraces about eight species, natives of South Europe, North and South Africa, Arabia, Australia, &c.

A. canariensis. A synonym of *Sesuvium Portulacastrum.*

AJUGA. Including *Chamæpithys.* The species of this genus number about thirty, and are distributed over extra-tropical regions. To those described on p. 45, Vol. I., the following varieties should be added:

A. reptans variegata (variegated). *l.* glaucous-green, with a broad, white edging. There are also purple-leaved and white-flowered forms of this species.

AKEBIA. Tribe *Lardizabaleæ* of Ord. *Berberideæ.* Four species of climbing shrubs, natives of China and Japan, are referred to this genus. Flowers violet, monœcious, in axillary, few-flowered racemes; sepals three, somewhat valvate; petals wanting. Leaves digitately

Akebia—*continued.*

three- to five-foliolate. To the species described on p. 45, Vol. I., the following should be added:

A. lobata (lobed). *fl.* pale purple, in a nodding or pendulous raceme; males numerous, ¼in. across; females few, below the males, ¼in. to 1in. across. January. *l.* long-petiolate, trifoliolate, 3in. to 5in. long; leaflets petiolulate, 1in. to 2in. long, broadly ovate, repand-lobulate. China and Japan, 1895. A tall, climbing shrub. (B. M. 7485.)

ALA (*pl.* Alæ). A wing.

ALANGIUM. ORD. *Cornaceæ.* This genus embraces eight or ten species, natives of tropical Asia and Africa.

ALARÇONIA. A synonym of **Wyethia** (which *see*).

ALATERNUS. *See* **Rhamnus Alaternus.**

ALBERTA (named in honour of Albertus Magnus, of the house of Bolstadt, a famous philosopher and theologian of the thirteenth century, who wrote a treatise in seven books entitled "De Vegetabilibus et Plantis"). ORD. *Rubiaceæ.* A small genus (two species) of ornamental, stove or greenhouse shrubs or small trees, one native of Madagascar and the other of Natal. Flowers small or rather large, in terminal panicles; calyx often coloured when fruiting, ten-ribbed, five-lobed; corolla tubular, elongated; stamens five. Fruit small, dry, two-celled. Leaves opposite, sub-sessile or petiolate. For culture of the only species introduced, *see* **Vangueria.**

A. magna (large). *fl.*, corolla reddish-purple, silky-pubescent, 1in. long, the segments obliquely ovate, acute. January and February. *fr.* oval, ¼in. long; calyx lobes scarlet, nearly 1in. long. *l.* shortly petiolate, oblong or elliptic-oblong, 4in. to 5in. long, 1½in. to 2in. broad, flat, with recurved margins. Young branches reddish-brown. Natal, 1891. (B. M. 7454.)

ALBIKIA. A synonym of **Hypolytrum** (which *see*).

ALBINA. A synonym of **Alpinia** (which *see*).

ALBIZZIA. This genus embraces about two dozen species, natives of the warmer regions of Asia, Africa, and Australia. Flowers generally five-parted, hermaphrodite or rarely polygamous; stamens white, pink, or (rarely) purple, elongated, usually numerous; peduncles axillary or paniculate at the tips of the branches, bearing globose heads or cylindrical spikes. Pods broadly linear, straight, flat-compressed, slender. Leaves bipinnate; leaflets small and many pairs or ample and few.

A. Lebbek (Lebbek). The correct name of *Acacia Lebbek.*

ALBUCA. About thirty species are known, all natives of South and tropical Africa. To those described on p. 45, Vol. I., the following should be added. They are Cape plants, and require greenhouse treatment except where otherwise stated. *See also* **Urginea.**

A. Allenæ (Mrs. Allen's). *fl.* greenish-white, about ¾in. long, disposed in a lax raceme. *l.* about six, lanceolate, flaccid, glabrous, 1ft. to 1½ft. long, 1½in. to 2in. broad. Stem 3ft. to 4ft. high. Bulb globose, 2in. or more in diameter. Zanzibar, 1887. A stove species, allied to *A. Wakefieldii.*

A. Buchanani (Buchanan's). *fl.* yellow, racemose, borne on a long, thin scape. *l.* linear. Bulb small, ovoid. Nyassaland, 1891. A stove species, nearly allied to *A. Wakefieldii.*

A. corymbosa (corymbose-flowered). *fl.* five or six in a lax corymb; perianth yellow, banded green, the inner segments hooded, connivent; outer stamens having no anthers; peduncle 6in. long. July. *l.* six to eight, terete, 1ft. or more in length. 1895.

A. fibrosa (fibrous). *fl.* three or four in a lax raceme; perianth pale yellow, broadly keeled with green, less than 1in. long; peduncle flexuous, glaucous, 1ft. long. August. *l.* two, terete, bright green, glabrous, 1ft. or more in length, ¼in. in diameter at base. Bulb small, the outer tunics clothed with persistent bristles, 1½in. to 2in. long. 1874.

A. Gardeni (Garden's). A synonym of *Speirantha convallarioides.*

A. glandulosa (glandular). *fl.* very fragrant, permanently erect; perianth white, banded with green, ¾in. long; raceme corymbose, three-flowered; peduncle 1ft. long, densely glandular. April. *l.* two or three, 6in. long, linear at base, ¼in. to ½in. broad, rounded at back. Bulb globose, 1in. in diameter. 1875.

A. juncifolia (Rush-leaved). *fl.* greenish-yellow, inodorous, drooping, ten to fifteen in a deltoid panicle 4in. to 5in. long; perianth 1in. long. August. *l.* twenty to thirty, sub-terete, 1ft. long, ¼in. to ½in. in diameter, tapering to a point. 1876. (B. M. 6395.)

Albuca—*continued.*

A. polyphylla (many-leaved). *fl.* few in a corymbose raceme; perianth white, banded with green, permanently erect; peduncle terete, 6in. long. March. *l.* twelve to fifteen, subulate, bright green, glabrous, 2in. to 3in. long, half a line broad. Bulb ovoid, 1½in. to 2in. in diameter. 1874.

A. trichophylla (hair-leaved). *fl.* few, arranged in a lax raceme 6in. long; perianth bright yellow, ¾in. long; peduncle as long as the leaves. *l.* seven or eight, erect, sub-terete, 9in. to 10in. long, ⅛in. in diameter, deeply channelled down the face. Bulb ¾in. in diameter. 1889.

A. Wakefieldii (Wakefield's). *fl.* pale green, ten to twelve in a lax raceme 6in. to 9in. long; perianth 1in. long, the inner segments bordered white; scape longer than the leaves. Autumn. *l.* four or five, linear-ensiform, flaccid, glabrous, 1ft. to 1½ft. long, 1in. broad at base, tapering to a point. Eastern tropical Africa, 1878. Stove. (B. M. 6429.)

ALCHORNEA (commemorative of Stanesby Alchorne, Assay-master in the Mint, who died in 1799 or 1800). Including *Cœlebogyne.* ORD. *Euphorbiaceæ.* A genus comprising about thirty species of stove or greenhouse trees or shrubs, inhabiting the warmer regions. Flowers diœcious or rarely monœcious, apetalous, in axillary or lateral spikes. Leaves alternate, entire or toothed. Only one species, *A. ilicifolia*, calls for mention here, and that not for any particular horticultural merit, but on account of the curious fact of its having reproduced itself from seed in European gardens (including Kew) through several generations from female plants alone, without the intervention of any male flowers.

ALECTOROLOPHUS. A synonym of **Rhinanthus** (which *see*).

ALEGRIA. A synonym of **Luhea** (which *see*).

ALETRIS. SYN. *Stachyopogon.* About eight species are included in this genus; they are found in North America, Japan, China, India, and Borneo.

ALEURITOPTERIS. *See* **Cheilanthes.**

ALEURODES, also called **ALEYRODES.** ORD. *Hemiptera.* A genus of very minute insects (about ¼in.) allied to the Aphides and the Scales. From the former, however, they differ in having broad powdery wings, as well as in their life-cycle; and from the latter in being four-winged in both sexes. The head is minute, and the eyes are divided. The antennæ, contrary to the general belief, are seven-jointed, though the articulations are not readily recognised. Signoret is one of the few naturalists who credit the insect with having seven-joints to the antennæ; the majority, and among them Bouché and Westwood, give but six. Signoret's description is as follows: 1, short, globose; 2, twice as long, clavate; 3, two and a-half times as long as 2, nearly as long as the last four, undulated, very small at its base, afterwards thicker; 4 and 7, of equal length, and shortest; 5 and 6, of equal length, and a little longer than 4 and 7; 5, globose at the extremity; the last five circularly striate. The wings are, as before stated, four in number, oval in shape, and when at rest are disposed nearly horizontally. The legs are short, simple, two-jointed; the tarsi are two-jointed and provided with two hooks. The larva is short, oval, flat, and generally scale-like in appearance. The pupa is fixed, and enveloped in the skin of the larva. There is, however, little to distinguish the one from the other generically. There are about twenty-five species, and all are extremely prolific.

The most noteworthy species is *A. proletella* (*A. chelidonii*) which infests a number of subjects, including such dissimilar ones as the Oak and the Cabbage. It is, however, in connection with the latter that the insect has chiefly been noticed in gardens. Mr. J. W. Douglas a few years ago described a new species, *A. ribium*, which he found on both Red and Black Currants. Fortunately this has not occurred in sufficient numbers to be regarded as pests. See also **Cabbage Powdered Wing** and **Snowy Fly.**

ALFONSIA. A synonym of **Elæis** (which *see*).

ALGA. A synonym of **Zostera** (which *see*).

ALIBERTIA. SYN. *Cordiera.* About a score species of trees and shrubs, restricted to tropical America, are included in this genus.

ALIBERTIA INTERMEDIA. A synonym of **Agave Alibertii** (which *see*).

ALIBREXIA. A synonym of **Dolia** (which *see*).

ALIPSA. A synonym of **Liparis** (which *see*).

ALISANDERS. *See* **Smyrnium.**

ALISMA NATANS. The correct name is *Elisma natans.*

ALKANNA (an Arabic name). SYNS. *Baphorhiza, Camptocarpus.* ORD. *Boragineæ.* A genus embracing nearly forty species of hispid or glutinous, mostly hardy, perennial herbs, natives of South Europe, North Africa, and Western Asia. Flowers yellow, blue, violet, or white, in simple racemes or cymes; calyx five-parted; corolla tube cylindrical, the five lobes imbricated. Leaves alternate. Roots often tinged with red. Only two species call for mention here. For culture, *see* **Lithospermum.**

A. orientalis (Eastern). *fl.* yellow; corolla tube twice as long as the calyx. June. *l.*, radical ones attenuated at base; cauline ones very narrow, decurrent; floral ones somewhat cordate-ovate at base. Stem ascending. Levant, 1813. SYN. *Lithospermum orientale* (B. M. 515).

A. tinctoria (dyers'). The correct name of *Anchusa tinctoria.* SYN. *Lithospermum tinctorium* (A. B. R. 576).

ALKEKENGI. *See* **Physalis Alkekengi.**

ALLAGOPTERA. A synonym of **Diplothemium** (which *see*).

ALLAMANDA. SYN. *Orelia.* A dozen species have been referred to this genus, but the rank of some of them is very uncertain; they inhabit South America, one extending as far as Central America. To those described on pp. 47-8, Vol. I., the following should be added:

A. Blanchetii (Blanchet's). A synonym of *A. violacea.*

A. cathartica Hendersoni (Henderson's). *fl.* orange-yellow, with five white spots at the throat, tinged brown outside, the lobes finely formed, immensely thick and wax-like. (R. G. 1887, pp. 560-1, f. 142.) SYNS. *A. Hendersoni* (F. M. 1866, 263; I. H. 1865, 452), *A. Wardleyana.*

A. c. Williamsii (Williams's). This form differs from the others in being of erect habit. 1891. (J. H. 1891, xxiii., f. 14, and Gn. xl., t. 832, under name of *A. Williamsii.*)

A. Hendersoni (Henderson's). A variety of *A. cathartica.*

A. magnifica (magnificent). A variety of *A. Schottii.*

A. Schottii magnifica (magnificent). *fl.* clear yellow, with a deep orange-yellow throat, about 5in. in diameter, freely produced in clusters. 1888.

A. violacea (violet). *fl.* rosy-purple, large, axillary and in few-flowered, tomentose cymes. October. *l.* three to five in whorls, sessile, oblong or obovate-oblong, cuspidate-acuminate, puberulous above, tomentose beneath. Branches pubescent-tomentose. Brazil, 1839. Plant erect or climbing. (B. M. 7122.) SYN. *A. Blanchetii.*

A. Wardleyana (Wardley's). A synonym of *A. cathartica Hendersoni.*

A. Williamsii (Williams's). A variety of *A. cathartica.*

ALLANTODIA. Like the strong-growing Asplениums, the Allantodia requires a substantial yet light soil, in which its fleshy roots delight to run: a mixture of equal parts fibrous peat, leaf mould, turfy loam, and silver sand, suits it best. The plant has a great objection to being potted hard, and to imperfect drainage. If there is stagnation of water about the roots the foliage soon becomes flabby and begins to show unmistakable signs of ill-health. The Allantodia is also averse to strong light, and to preserve the bright green colour peculiar to its fronds it is necessary to protect them from the strong rays of the sun. The waterings must be copious during the summer, and gradually lessened, until in winter the roots are kept only sufficiently moist to prevent the plant from shrivelling. The propagation of this species is effected exclusively from spores, which are produced in abundance and germinate freely.

A. australis. A synonym of *Asplenium umbrosum.*

ALL-HEAL. *See also* **Valeriana officinalis.**

ALLIONIA (named in compliment to C. Allioni, an Italian botanist). SYN. *Wedelia* (of Linnæus). ORD. *Nyctagineæ.* A monotypic genus. The species, *A. involucrata,* is a prostrate, dichotomously branched, American annual, allied to *Mirabilis,* with small, purple flowers, and opposite, entire leaves. It has no particular horticultural value.

ALLIONIA (of Loefler). A synonym of **Oxybaphus** (which *see*).

ALLIUM. Including *Nectaroscordum* and *Ophioscorodon.* This genus embraces about 250 species, mostly inhabiting Europe, North Africa, Abyssinia, and extra-tropical Asia, but many are found in North America and Mexico. Our garden Leek (*A. Porrum*) is a cultivated form of *A. Ampeloprasum;* Chives, of *A. Schœnoprasum;* and Rocambole, of *A. Scorodoprasum,* all of which are British plants.

A. neapolitanum, the well-known South European species, may be employed as a pot plant, and is useful for forcing. The bulbs should be potted up in autumn, using well-drained pots and a sandy soil. They should then be stood in a bed of ashes outside and covered with cocoa-fibre. When well-rooted, and top growth is evident, they should be transferred to a cold frame, and shaded for a few days, after which they may be stood in the greenhouse. *A. neapolitanum* is one of the flowers which is sent into this country in vast quantities in early spring, and is commonly, but erroneously, called Star of Bethlehem.

To the species described on pp. 48-9, Vol. I., the following should be added:

A. Akaka (Akaka). *fl.* rose-coloured, ¼in. long; umbel dense, many-flowered, convex. Spring. *l.* usually in pairs, flat, ovate or ovate-oblong, ¾in. to 1¼in. broad, obtuse or with a short point at apex. Stem very short. Bulb ovate. North Persia, 1894. Allied to *A. karataviense.*

A. album (white). A synonym of *A. neapolitanum.*

A. Alexianum (Alexis'). *fl.* whitish, striped with brownish-purple; umbel many-flowered, somewhat fastigiate, convex. *l.* two, three, or more, elliptic-oblong or oblong-lanceolate, 1in. to 2in. broad, the inner ones often narrower, glabrous. Bulb sub-globose. Turkestan, 1889.

A. amblyophyllum (obtuse-leaved). *fl.* lilac; perianth segments lanceolate, acute; umbel about 1½in. in diameter, globose. Summer. *l.* five or six, broad, linear, obtuse, flat, spaced along the stem. Bulb small. Turkestan, 1885. A rather distinct species, of dwarf habit. (R. G. 1190.)

A. anceps (two-edged). *fl.* purple or greenish-white, ¼in. long; umbel very many-flowered, fastigiate. May. *l.* broadly linear, attenuated at both ends, falcate or more or less curved. Stems erect, ancipitous, shorter than the leaves. Bulb ovate. North-west America, 1875. (B. M. 6227.)

A. Backhousianum (Backhouse's). *fl.* white, in a dense, globose head; perianth segments narrow-linear and totally reflexed; stamens united into a cup at the base. *l.* radical, bluish-white. *h.* 3ft. to 4ft. Himalayas, 1885. A tall species, resembling *A. giganteum.* (R. G. 1885, 215.)

A. cabulicum (Kabul). *fl.* whitish, with keels of reddish-brown; umbel dense, globose, many-flowered, about 2in. in diameter. *l.* single, lorate-oblong, glabrous, 6in. to 8in. long, 2in. broad, gradually narrowed to the clasping base. Kabul, 1893. (B. M. 7294.)

A. ciliatum (ciliated). A synonym of *A. subhirsutum.*

A. cyaneum (blue). *fl.* very numerous, in a hemispherical or sub-globose umbel; perianth blue, campanulate. *l.* narrow-linear or filiform, channelled above. Stems erect or slightly nodding at apex, 6in. to 12in. high. Bulbs tufted, elongated. Kansu, China, 1890. (R. G. 1316.)

A. c. brachystemon (short-stamened). A synonym of *A. kansuense.*

A. clatum (tall). *fl.* purple, numerous, disposed in a large, globose head; perianth segments spreading, oblong, obtuse; scape stout, 3ft. or more high. *l.* oblong, obtuse, 8in. to 12in. long, 2in. to 4in. broad. Central Asia, 1887. (R. G. 1251.)

A. Fetisowi (Fetisow's). *fl.* of a rosy-lilac; umbel many-flowered, at first hemispherical, at length sub-globose. *l.* oblong- or linear-lanceolate, flat, 10in. to 16in. long. Stems erect, 2ft. high, terete, smooth, with one or two leaves at the base. Turkestan, 1879.

A. fragrans (fragrant). A synonym of *Nothoscordum fragrans.*

A. giganteum (gigantic). *fl.* numerous, forming a dense globose umbel 4in. in diameter; perianth bright lilac, ¾in. long, the segments widely spreading; peduncle erect, 3ft. to 4ft.

Allium—*continued.*

long. June. *l.* six to nine, springing from the base of the peduncle, lorate, flaccid, glaucescent, 1½ft. long, 2in. broad in the middle. Bulb globose, 2in. to 3in. in diameter. Merv, 1883. (B. M. 6823; R. G. 1113.)

A. Holtzeri (Holtzer's). *fl.* many, in a capitate, hemispherical umbel 1½in. in diameter; perianth white, the segments elliptic-oblong, acute, with a green middle nerve; anthers red; ovary green, prominent; scape flexuous, 5in. to 7in. long. *l.* filiform, more or less terete, equalling or exceeding the scape, glabrous. Bulbs fascicled-tufted, oblong-cylindrical. Turkestan, 1884. (R. G. 1169, a-c.)

A. kansuense (Kansu).* *fl.* blue, with the stamens shorter than the perianth segments; umbel hemispherical, many-flowered. *l.* linear, channelled in the lower part, having the margins rough. Stem leafy to near the middle. Bulbs slender, cylindric, tufted. Kansu, China, 1889. (R. G. 1870, 1317.) SYN. *A. cyaneum brachystemon.*

A. lacteum (milky). A synonym of *A. neapolitanum.*

A. Macleanii (Maclean's). *fl.* in a dense, globose umbel 3in. to 4in. in diameter; perianth mauve-purple, ¾in. long, the segments oblong-lanceolate, acute; spathe valves two, membranous; peduncle flexuous, 2ft. to 3ft. long. Summer. *l.* four or five, evanescent, lanceolate, about 1ft. long, 1in. to 1½in. broad, glabrous. Kabul, 1882. (B. M. 6707.)

A. macranthum (large-flowered). *fl.* fifty or more in a loose, globose umbel 3in. to 4in. in diameter; perianth bright mauve-purple, nearly ¾in. long, permanently campanulate; pedicels 1½in. to 2in. long; scapes several in a tuft, 2ft. to 3ft. long. July. *l.* numerous, linear, thin, 1ft. to 1½ft. long, tapering gradually to a long point. Rootstock indistinctly bulbous, with a dense tuft of fleshy root-fibres. Eastern Himalayas, 1883. (B. M. 6789.)

A. narcissiflorum (Narcissus-flowered).* *fl.* of a beautiful rose-colour, campanulate, ¾in. long; umbel at first nodding, then erect, few-flowered, fastigiate or almost hemispherical. *l.* linear. Stems erect, terete, striated, 4in. to 15in. high. Bulbs tufted. Italy, &c., 1875. (B. M. 6182.)

A. oreophilum (mountain-loving). *fl.* reddish-purple, nearly ¼in. long; umbel very many- (or rarely few-) flowered. *l.* linear, broadly linear, or narrowly linear-lanceolate, channelled above, convex beneath. Stems 1½in. to 4in. above the ground. Bulb sub-globose, white-skinned. Caucasus, Siberia, &c. (R. G. 1873, t. 775, f. 1-3.)

A. orientale (Oriental). *fl.* white, with greenish or reddish nerves; umbel many-flowered, almost hemispherical. *l.* linear-lanceolate, ¼in. to ¾in. broad, very flexuous or undulated, attenuated-acute. Stems erect, 4in. to 8in. high, with one or two leaves at base. Bulb large, roundish-ovate, white-skinned. Syria.

A. o. rubellum (reddish). *fl.* bright rose-coloured. *l.* small, glaucous. 1889.

A. Ostrowskianum (Ostrowsky's).* *fl.* rose-coloured, disposed in a many-flowered umbel; scape 8in. to 12in. high. *l.* two or three, linear, flat, flaccid, acute, glaucous. Turkestan, 1883. (R. G. 1089.)

A. oviflorum (ovate-flowered). *fl.* deep violet-purple, ovate-conical, nodding; sepals connivent; umbel lax, roundish; scape acutely four- to six-angled. *l.* produced at the apex of the short, bulbless stems, sub-biseriate, lax, keeled, glabrous. Chumbi Valley, India, 1883. A pretty and interesting plant. (R. G. 1134.)

A. parciflorum (scanty-flowered). *fl.* purple, small, three to six in an umbel. *l.* two to four, slender, filiform, placed at from one-third to half-way up the stems. Stems one to three, slender, 4in. to 10in. high. Bulb ovoid. Corsica and Sardinia, 1838. SYN. *A. pauciflorum.*

A. pauciflorum (few-flowered). A synonym of *A. parciflorum.*

A. Przewalskianum (Przewalski's). *fl.* rosy-lilac; umbel many-flowered, hemispherical or fascicled. *l.* semi-terete-filiform. Stems terete, slender, 6in. to 10in. high, leafy below. Bulbs tufted, conico-cylindrical. Kansu, China, 1889.

A. pulchellum (rather pretty). *fl.* violet; perianth obconical-campanulate; filaments one-and-a-half times longer than the perianth; umbels many-flowered; scape tall, terete, leafy to the middle. *l.* narrow-linear, channelled above, striated beneath, equalling the scape. Orient.

A. Schuberti (Schubert's).* *fl.*, perianth rose-red, the segments connate at base, lanceolate, acute, twice exceeding the stamens; umbel very large (sometimes 1ft. in diameter when bearing seed), sub-globose, containing fifty to 200 flowers; scape terete, thick, about 1ft. high. *l.* broadly lorate-lanceolate, flat, more or less undulated. Bulb ovate, thick. Orient, 1898. (B. M. 7587-8.)

A. Semenovi (Semenow's). *fl.* yellow, on very short pedicels; outer perianth segments longer than the inner ones; stamens very short, united in a tube round the ovary; umbel small, dense; scape usually shorter than the leaves. *l.* glaucous, fistular, flat on the face, rounded at back. Alatau Mountains, 1884. (R. G. 1156.)

A. semiretschenskianum (name not explained). *fl* flesh coloured, 1½in. long; umbel many-flowered, hemispherical. *l.* linear, channelled above, convex beneath. Stems erect, terete, 1½ft. high. Bulb tunics entire. Wernoe, 1879.

Allium—*continued.*

A. Sprengeri (Sprenger's). *fl.* yellowish, many in an umbel. *l.* flat, linear. Bulbs ovoid, crowded on a short rhizome. Jaffa, Syria. 1889.

A. stipitatum (stalked). *fl.* rosy-lilac, odorous; umbel hemispherical or sub-globose, bractless. *l.* all radical, narrow-linear-lanceolate, slightly hairy on the margins, glabrous above. Stem 2½ft. to 3ft. high. Bokhara, 1881.

A. subhirsutum (somewhat hairy). *fl.* white, or with the middle nerve more or less purplish; umbel few- or many-flowered, convex. July. *l.* broadly linear, more or less villous or hairy, attenuated-acute towards the apex. Stems erect, 4in. to 12in. high. Bulb ovate-globose. South Europe. (L. B. C. 943.) SYN. *A ciliatum* (B. M. 774).

A. Suworowi (Suworow's). *fl.*, perianth dark mauve-purple, ¼in. long, the segments keeled with green; umbel very dense, globose, 2in. to 3in. in diameter; scape stout, erect, 2ft. long. May and summer. *l.* six or seven in a basal rosette, ensiform, 1ft. to 1½ft. long, 1in. broad, glaucous-green, flaccid. Central Asia. (B. M. 6994.)

ALLOMORPHIA (from *allos*, diverse, and *morphe*, form; application not obvious). ORD. *Melastomaceæ.* A small genus (two or three species) of stove, branched shrubs or under-shrubs, natives of the Malayan Peninsula and islands. Flowers small, whorled, in terminal or almost radical panicles; calyx obtusely four- or five-toothed, persistent; petals four or five, acute, small; stamens eight or ten, almost equal. Leaves long-stalked, ample, ovate, ovate-oblong, or orbicular, entire or slightly toothed. Only one species has been introduced. For culture, *see* **Melastoma.**

A. Griffithii (Griffith's). *fl.* white, numerous, spreading; panicle elongated, narrow; scape red, erect, 8in. long. June. *l.* ample, orbicular, deeply cordate, leathery, glandular-toothed, seven- to nine-ribbed, bronzy green above, reddish beneath. Malayan Peninsula, 1893. (B. M. 7324.)

ALLOPHYLLUS. A synonym of **Schmidelia** (which *see*).

ALLOPLECTUS. SYNS. *Crantzia* (of Scopoli) *Lophia.* Including *Heintzia* and *Macrochlamys.* About thirty species have been referred to this genus, all natives of tropical America, from Brazil to the West Indies and Central America. To those described on p. 49, Vol. I., the following should be added:

A. concolor (one-coloured). A form of *A. dichrous*, with red flowers. Brazil, 1846. (B. M. 4371.)

A. Lynchei (Lynch's). *fl.* yellow, hairy, in axillary clusters, the large calyces tinged with red. July. *l.* oblong-lanceolate, acuminate, unequally crenate-serrate, green above with a red midrib and veins, sanguineous-purple beneath, thickened into a short petiole. Stem robust. Colombia (?), 1890. (B. M. 7271.)

A. Schlimii (Schlim's). *fl.*, calyx cinnabar, spotted with green, large; corolla scarlet or yellowish in the lower part, of a beautiful violet above, urceolate, nearly regular; pedicels, axillary, twin or few. *l.* oblong, acuminate, rounded or almost cordate at base, dark green above, purplish-violet beneath. Colombia, 1851. (F. d. S. 827.)

A. tigrinus (tiger-marked). *fl.* erect or nearly so; calyx yellowish-green, tinged with red; corolla white, funnel-shaped, half as long again as the calyx, the lobes spotted with purple. Midwinter. *l.* large, opposite, fleshy, ovate, acuminate, hoary and pale beneath, strongly veined. *h.* 2ft. to 5ft. Caracas, 1852. SYN. *Heintzia tigrina.* (B. M. 4774.)

ALLOTMENTS. These are readily procured in any district where the demand for such exists, as they are now regulated by Acts of Parliament—the Allotments Act of 1887, the Allotments Act of 1890, and the Local Government Act of 1894—the duty of making enquiries into such demands for allotments being delegated to the sanitary authority. Parish councils also have power to hire land for allotment purposes, and if they are satisfied that allotments are required, and are unable to hire by agreement land suitable for the purpose, they may make representations to the County Council. That body is still further empowered, and may make an order authorising the Parish Council to hire compulsorily such land as they specify. The period over which such hiring extends must not be less than fourteen years, nor more than thirty-five years. It is also provided that the Parish Council

Allotments—*continued.*

may let to one person an allotment or allotments exeeeding one acre; but in the case of compulsorily hired land it must not exceed four acres of pasture or an acre of arable and three acres of pasture. By the Allotments Compensation Act holders are, moreover, compensated for growing crops, labour, and manure expended in anticipation of a crop; and where the previous consent of the landlord has been obtained for fruit-trees, bushes, drainage, and such buildings as are allowed to be erected. This Act applies alike to cottage gardens and to holdings under two acres cultivated as a garden or as a farm, or partly as a garden or as a farm. Another point for which provision is made is to relieve holders of allotments from being assessed for sanitary purposes at a higher rate than other lands under cultivation. At one time England only was included in the Act, but now Scotland also participates.

ALMEIDIA. SYN. *Aruba.* About ten species are known, all natives of Brazil.

ALNUS. Including *Clethropsis.* About fourteen species, broadly dispersed over Europe, Central and North Asia, North America, and the Andes of South America, are here included. The only British species is *A. glutinosa.*

The gold and silver-leaved varieties may be increased by grafting in the open air in March on stocks of the common species *(Alnus glutinosa),* which should have been inserted the previous spring, as the plants should be firmly established before the scions are put on. The latter should be of well-ripened wood and about 4in. in length.

To the species, &c., described on p. 50, Vol. I., the following should be added:

A. acuminata (taper-pointed). *barren catkins* cylindrical, sessile or pedicellate, often racemose and terminal, rarely axillary. *fertile catkins* ovate-oblong, racemose, usually axillary. *l.* ovate or roundish-ovate, usually acuminate, rarely acute, rounded at base, irregularly or doubly toothed. Mountains of tropical America, &c.

A. a. Mirbelii (Mirbel's). *l.* unequally toothed, glaucous beneath, the nerves and veins pale ferruginous-pubescent. Peru, &c.

A. cordata (cordate). A synonym of *A. cordifolia.*

A. glutinosa acutifolia (acute-leaved). *l.* obovate or oblong, almost acuminate at apex, wedge-shaped at base. SYN. *A. oblongata.*

A. incana hirsuta (hairy). *l.* almost orbicular, obtuse, downy on both surfaces.

A. i. pendula nova (pendulous, new). An elegant, weeping variety, adapted for moist places.

A. i. pinnatifida (pinnately cleft). *l.* pinnatifid.

A. i. sibirica (Siberian). *l.* elliptic-orbicular, glabrescent, heart-shaped at base, rounded at the apex.

A. japonica (Japanese). *catkins* ellipsoid, obtuse, ½in. to ¾in. long, nearly or quite ¼in. thick. *l.* elliptic or elliptic-ovate, acuminate, serrated, acute at base, 2in. to 4in. long, 1in. to 2in. broad. Japan, 1836. Tree. (G. & F. 1893, p. 345, f. 53.)

A. Mirbelii (Mirbel's). A variety of *A. acuminata.*

A. nepalensis (Nepaul). *barren catkins* 4in. to 10in. long, in terminal, drooping panicles. *fertile catkins* ½in. long, pendulous in flower. *fr.*, spikes in lateral, erect panicles. *l.* elliptic-lanceolate, acute, entire or nearly so, 3in. to 7in. long, 2in. to 4in. broad, slightly glaucous beneath; petioles ½in. to 2in. long. Temperate Himalayas. SYN. *Clethropsis nepalensis.*

A. nitida (shining).* *fl.* appearing after the leaves; barren catkins 2in. long, in terminal, erect racemes; fertile catkins 1in. to 2in. long. *fr.*, spikes solitary or in erect racemes. *l.* elliptic-ovate or elliptic-acuminate, 4in. to 8in. long, sometimes 3½in. broad, obscurely crenate or entire, cuneate or rarely rounded at base. Branchlets pubescent. Trunk sometimes 15ft. in girth. *h.* 100ft. Temperate Himalayas. (B. M. 7654.)

A. oblongata (oblong). A synonym of *A. glutinosa acutifolia.*

A. oregana (Oregon). A form of *A. rubra.*

A. orientalis (Eastern). *catkins,* young ones of both sexes glutinous, pedunculate. *l.* ovate-elliptic or ovate-oblong, rounded or rarely almost cordate at base, the margins simply or doubly crenate-toothed. Orient, &c.

A. pubescens (downy). A hybrid between *A. glutinosa* and *A. incana.*

A. rhombifolia (rhomb-leaved).* *l.* ovate or ovate-oblong, 2in. to 3in. long, obtuse or acute, cuneate at base, irregularly glandular-toothed, smooth above, slightly pubescent beneath.

Alnus—*continued.*

California, 1888. An ornamental tree, similar to *A. rubra,* but having slenderer branches, the dark brown bark scarcely dotted with white, and the nutlets with a thickened margin, not winged. (Sargent, Silva of N. America, p. 456—California, &c.)

A. rubra (red). *catkins* ovate-elliptic. *fr.*, nutlets winged. *l.* ovate-elliptic, obtusely lobulate or crenate, large, petiolate, acute or obtuse, glaucescent and prominently reddish on the nerves beneath, highly glabrous on both sides. *h.* 20ft. Vancouver Island, &c. *A. oregana* is a form of this species.

A. serrulata (slightly serrated). *barren catkins* elongated, drooping. *fertile catkins* ovoid, shortly pedunculate. January to March. *l.* obovate, obtuse or abruptly pointed, 2in. to 4in. long, thickish, usually pubescent beneath, acute at base, shortly petiolate; stipules oval, obtuse. *h.* 3ft. to 12ft. North America, 1769.

A. sibirica (Siberian), of Fischer. A form of *A. incana.*

A. sibirica, of gardens. A synonym of *A. glutinosa.*

A. virescens (greenish). A handsome Alder, allied to *A. incana.* Colorado, 1897.

ALOCASIA. In addition to the score of species, natives of tropical Asia, the Malayan Archipelago, &c., there is now a good selection of hybrid Alocasias. To those described on pp. 50-1, Vol. I., the following should be added:

A. æquiloba (equal-lobed). *fl.*, spathe shining green, the tube 1½in. long, the limb 2½in. long, oblong, acute, reflexed, with revolute margins; peduncle 9in. or more in length. *l.* hastate-sagittate, the terminal lobe 7in. to 12in. long, 3in. to 6in. broad, shortly cuspidate at apex, the basal lobes 6½in. to 12½in. long, 1½in. to 2½in. broad. German New Guinea, 1895. Plant glabrous.

A. albo-violacea (white and violet). A synonym of *Xanthosoma maculatum.*

A. argyræa (silvery). *l.* hastate-lanceolate, very large, dark green, with a silvery sheen, and having a prominent midrib. 1895.

A. argyroneura (silvery-nerved). A synonym of *Caladium Schomburgkii.*

A. Augustiana (Auguste Linden's). *l.* peltate, repand, green, the primary nerves paler, as is also the under-surface; petioles 1ft. to 1½ft. long, ¾in. to 1¼in. thick at base, terete, rosy, with brown hieroglyphic spots. 1886. (I. H. 1886, 593).

A. Chantrieri (Chantrier's).* *l.* about 1ft. long and 6in. broad, oblong-sagittate, peltate, with undulated margins, deep olive-green above, the veins narrowly bordered with silvery white; under-surface deep violet-red; petioles slightly dilated, with sheathing base, cylindrical, green, lightly barred with olive. A hybrid between *A. metallica* and *A. Sanderiana.* (I. H. xxxv. t. 64; R. H. 1887, p. 465.)

A. coriacea (leathery). *l.* dark green, with clear green ribs; petioles rose-coloured when young, then rosy-white, marbled with green. 1893.

A. Curtisii (Curtis's). *fl.*, spathe pale yellow, 6in. long; spadix yellow, as long as the spathe; peduncle 1ft. long. *l.* 1½ft. long, 1ft. broad, with long basal lobes, light and dark green above, purple on the lower surface; petioles about 2ft. long. Penang, 1894.

A. denudata (denuded). *fl.* on a long, slender peduncle. *l.* triangular-sagittate, shortly acuminate, about one-third as broad as long, the basal lobes nearly as long as the anticous, the costæ marginal. India and Singapore.

A. Dussii (Duss's). *l.* large, olive-green, with brownish-red nerves and petioles. 1893.

A. eminens (eminent). *fl.*, spathe tube light green, 1½in. long, the lamina greenish-white, veiny, 3½in. to 4in. long, reflexed; spadix light green and creamy-white, 3½in. to 4½in. long; peduncles in pairs (? always), 1ft. to 1½ft. long. *l.* peltate, ovate-sagittate, 20in. to 22in. long, 9in. to 10½in. broad, dark green above, the under-surface purple, with very pale midrib and primary veins; petioles 3½ft. to 4½ft. long, terete, 1in. thick at base, olive-green, with a coppery hue, and barred blackish-green. Malaya, 1887.

A. erythræa (red). A synonym of *Caladium Schomburgki Schmitzii.*

A. Gaulainii (Gaulain's). *l.* cordate, dark green above with a violet hue along the nerves, beneath light violet with blackish nerves. 1890. A robust plant.

A. gigas (gigantic). *l.* 5ft. high, of an intense green above, paler beneath, deeply cut; petioles pale green, mottled. 1897. A handsome plant, remarkable for its size.

A. grandis (large).* *fl.*, spathe white, marked with carmine lines on the outside, having a short, mottled green tube; peduncles about 10in. long. *l.* ovate-sagittate, 1¾ft. to 2ft. long, 1ft. broad, bright green above, blackish-green beneath; petioles blackish, 3ft. to 3½ft. long. East Indian Archipelago, 1886. A noble and ornamental plant.

A. guttata imperialis (imperial). *fl.*, spathe white, spotted red on the tube. *l.* elliptic-sagittate, acute, 1ft. to 1½ft. long,

Alocasia—*continued.*

¾ft. to 1¼ft. broad, dark green above with slightly paler spaces between the nerves, purplish beneath. Borneo, 1885. A fine foliage plant. (I. H. 1884, 541.)

A. indica (Indian). *fl.*, spathe pale yellow-green, 8in. to 12in. long; spadix as long. *l.* 2ft. to 3ft. long, ovate, deeply sagittate-cordate, repand, the tip a deflexed cusp, the basal lobes sometimes shortly connate; petioles stout, traversely clouded. Stem 8ft. high, 3in. to 8in. in diameter. Tropical Asia.

A. Johnstoni. The correct name is *Cyrtosperma Johnstoni.*

A. Lindeni (Auguste Linden's).* *l.* 8in. long, 4½in. to 6in. broad, glabrous, green above, with yellowish-white midrib and principal veins, paler beneath, cordate-ovate, very long-acuminate, the sinus large, triangular; petioles white or greenish-white, 10in. to 12in. long, ½in. to ¾in. thick, erect, terete, channelled, amplexicaul, with decurrent sheaths half their length. Malaya, 1886. (I. H. 1886, 603.)

FIG 35. ALOCASIA LOWII GRANDIS.

A. Lowii grandis (large). *l.* broader than in the type, of a deeper metallic brownish-green; veins greyish-green, showy. 1895. A fine variety. See Fig. 35.

A. Luciani (Lucien Linden's). *l.* peltate, ovate, cuspidate at apex, obcordate at base, dark green above, with pale cinereous veins and margins, purple beneath; basal lobes ovate-deltoid; petioles very long, thick, pale, dotted and spotted brown. 1887. A hybrid between *A. Thibautiana* and *A. Putzeysi.* (I. H. ser. v. 27.)

A. Margaritæ (Marguerite's). *l.* large, obcordate, peltate, repand, rather thick, bullate, highly glabrous above, except on the blackish midrib and primary veins; sinus triangular, the apex at the junction of the petiole; petioles terete, puberulous, brownish-purple, sheathing at base, the sheaths rosy-margined. Java, 1886. (I. H. 1886, 611.)

A. marginata (margined). *fl.*, spathe tube green, 1in. to 1½in. long, the lamina pale greenish-white, usually striped and spotted dull purple at back; spadix white, 6in. to 7in. long. *l.* 1½ft. to 2ft. long, 11in. to 14in. broad, broadly cordate-ovate, slightly sinuate-margined, rounded into a shortly-pointed apex; petioles 2ft. to 3½ft. long, with zigzag marks of blackish-brown, the sheaths broadly margined with blackish-brown. Brazil. 1887.

A. odora (odorous). The correct name of *Colocasia odorata.*

A. Portei. *See* **Schizocasia Portei.**

A. princeps (foremost). *l.* sagittate, the hinder lobes narrow and spreading, forming a triangular, open sinus, the margins deeply sinuate, the upper surface of a metallic olive-green, with darkened midribs and primary veins, the under-surface greyish-green, with dark chocolate-brown veins and margin; petioles slender, greyish-green, heavily marbled chocolate-brown. Malayan Archipelago, 1888.

A. Pucciana (Signor Pucci's). *l.* peltate, oval-sagittate, 1½ft. long, about 9in. broad, deep green above, the pure white veins surrounded by a silvery-white zone; under-surface glossy purplish; petioles fleshy, smooth, cylindrical, pale purplish, marked with wavy, irregular zones of dull crimson-red; in the upper portion these markings disappear. 1887. Garden hybrid.

A. Putzeysi (Putzeys').* *l.* similar in shape to those of *A. longiloba*, dark green, the midrib, primary and secondary veins, and margins bordered with white; under-surface dark purple. Sumatra, 1882. (I. H. 445.) SYN. *A Watsoniana* (G. C. 1893, xiii., p. 442, f. 83).

A. Regina (queen). *fl.*, spathe tube ovoid, 1in. long, 3in. to 4in. in diameter, ivory-white, spotted purple, the blade white,

Alocasia—*continued.*

2in. to 2½in. long, reflexed; spadix sessile, rather shorter than the spathe. *l.* ovate-cordate, repand, somewhat fleshy, glabrous above, except the pubescent midrib and veins, dull brownish-purple beneath; petioles terete, spotted fuscous-purple. Borneo, 1885. (I. H. 1885, 544.)

A. Regnieri. *See* **Schizocasia Regnieri.**

A. reversa (reversed). *l.* ovate-sagittate, greyish-green, the primary veins broadly bordered with dark green. *h.* less than 1ft. Philippine Islands, 1890. An attractive foliage plant. (B. M. 7498.)

A. Sanderiana (Sander's).* *l.* deflexed, glossy, arrow-shaped, with three lateral lobes on each side, peltately affixed, the midrib and borders ivory-white, the surface bright green, with metallic-blue reflections; petioles erect, brownish-green, striately mottled. Philippines, 1884.

A. S. gandavensis (Ghent). *l.*, young ones purplish, with vermilion-tinted veins, these colours remaining constant above, but changing to green beneath. 1896. (I. H. 1896, t. 65.)

A. S. nobilis (noble). *l.* large, dark metallic green, with bronzy-red reflections; midrib and prominent veins greenish-white, margined on either side with a band of greyish-rose. 1893.

A. singaporensis (Singapore). This mainly differs from *A. denudata* in having triangular-ovate-hastate leaves with divaricate lobes. *h.* 1½ft. Singapore.

A. sinuata (sinuate). *fl.*, spathe light green, 3in. long; spadix shorter than the spathe; peduncle as long as, or longer than, the petioles. *l.* sagittate, with sinuate margins; upper side of the young ones very dark green along the principal veins, with a lighter green between; older ones dark green above, the under-side whitish-green. Philippines, 1885.

A. Veitchii (Veitch's). A synonym of *A. Lowii.*

A. Villeneuvei (Comte de Villeneuve's). *l.*, blades very unequal; petioles wholly spotted with brown. Borneo, 1887. Closely allied to *A. longiloba.* (I. H. ser. v. 21.)

A. Watsoniana (Watson's). A synonym of *A. Putzeysii.*

A. intermedia, *A. Kerchovei*, and *A. Martin Cahuzac* are other forms in cultivation.

Other garden hybrids are: *conspicua*, *gibba*, *mortfontanensis*, *nobilis*, *Rex*, *Rodigasiana*, and *Uhinki.*

ALOË. Including *Bowiea* (of Haworth), *Pachidendron*, and *Rhipodendron.* The name *Aloë* is in common use for *Agave*, which belongs to a different natural order; there is a widespread, but totally erroneous, belief that the *Aloë* (meaning the *Agave*) flowers only once in 100 years. *See* **Agave.**

These succulents are largely employed for the decoration of the greenhouse, their foliage varying considerably, and being, in some cases, very ornamental. To the species described on pp. 51-3, Vol. I., the following should be added. Several plants formerly classed hereunder are now referred to **Haworthia.**

A. abyssinica. In addition to *Peacockii*, the following varieties exist in Continental gardens: *erecta* (erect), *glauca* (bluish-green), *maculata* (spotted), *pygmæa* (dwarf), *recurvata* (recurved), and *robusta* (stout).

A. aurantiaca (orange). *fl.* all deflexed; perianth bright yellow, tinged with red when young, 1½in. long; raceme very dense, 5in. to 6in. long, 2in. in diameter; peduncle as long as the leaves. *l.* lanceolate, 8in. to 9in. long, 1½in. broad, plain green, with small pale teeth. Stems sub-erect, several feet long, ¾in. thick. 1892.

A. brachystachys (short-spiked). *fl.* pink and yellow, tubular, tipped with green, 1½in. long, the lobes lingulate, shorter than the tube; raceme dense, simple, oblong, 6in. long; peduncle flexuous, about as long as the leaves. *l.* about twenty, crowded at the top of the stem, ensiform, 1½ft. to 2ft. long, ½in. thick; marginal prickles deltoid. Stem long, slender, erect, simple. Zanzibar, 1884. (B. M. 7399.)

A. Buchanani (Buchanan's). *fl.* pale reddish and greenish, 1in. long, on very long pedicels; raceme dense, few-flowered; scape simple, 1½ft. long. *l.*, produced ones eight to ten, 1in. to 1½ft. long, ½in. broad at base, linear-subulate, distichous, deeply channelled, often white-spotted towards the base; marginal prickles few, very minute. Shiré Highlands, Tropical Africa, 1894.

A. ciliaris (ciliated). The correct name of *A. ciliata.*

A. ferox (fierce). *fl.*, perianth red, clavate, 1½in. long; raceme very dense, 1ft. or more in length; pedicels very short; peduncle 2ft. long, branched near the base. *l.* thirty to fifty, densely aggregated, lanceolate, 1½ft. to 2ft. long, 4in. to 6in. broad, with thick, brown marginal prickles. Stem 10ft. to 15ft. high, 4in. to 6in. thick. (B. M. 1975.)

A. heteracantha (variable-spined). *fl.* bright coral-red, 1½in. long; spike elongated, dense; flower-stem branching. *l.* in a rosette, lanceolate, acuminate, 6in. to 12in. long, 1½in. to 2½in. broad, unarmed, or with a few teeth on the margins, and with one or two raised lines down the face. Native country unknown. 1886. (B. M. 6863.)

Aloë—*continued.*

A. Hildebrandtii (Hildebrandt's). *fl.*, perianth cylindrical, less than 1in. long, the outer segments red, the inner ones reddish-yellow, with a green keel; panicle lax, 1½ft. long; peduncle short, compressed. *l.* loosely disposed, spreading, lanceolate, 6in. to 10in. long, 1½in. to 2in. broad at the clasping base, gradually tapering to an acuminate point, rounded at back, the margins toothed. Stem simple, erect, 1½ft. to 2ft. long. Eastern tropical Africa, 1882. (B. M. 6931.)

A. insignis (remarkable). *fl.* racemose, numerous; perianth whitish, lined green towards the apex, straight, fifteen to sixteen lines long; stamens exserted; peduncle 18in. to 20in. high, clothed with whitish bracts. *l.* thirty to forty, ascending, often incurved and slightly falcate, glaucous-green, 7in. to 11in. long, 1in. to 1½in. broad at base, tapering to a fine point, with tubercular points on the convex back. Stem about 3in. high. 1885. Hybrid. (G. C. n. s., xxiv., p. 41.)

A. Kirkii (Kirk's). *fl.* reddish-yellow, tipped with brown, above 1in. long; inflorescence 2ft. long, with three branches; racemes dense, the end one nearly 1ft. long. *l.* thirty to forty in a dense rosette, spreading, lanceolate, nearly 1ft. long, 2in. broad, ¼in. thick, very smooth, with large marginal teeth. Caudex short, stout, erect. Zanzibar, 1893. (B. M. 7386.)

A. longiaristata (long-awned). A synonym of *A. aristata.*

A. longiflora (long-flowered). *fl.*, perianth primrose-yellow, cylindrical, 1½in. long; raceme dense, simple, 6in. to 8in. long; pedicels erecto-patent; peduncle shorter than the raceme. *l.* spreading, ensiform, 1¼ft. to 1½ft. long, 1½in. broad, gradually tapering to a long point, glossy-green, unspotted, with crowded marginal teeth. Stem simple, 1½ft. long below the rosette. 1885. (G. C. 1883, iv., p. 756.)

A. Luntii (W. Lunt's). *fl.* reddish-green at the tips, less than 1in. long; panicle consisting of four or five long, lax, racemes, the side ones spreading horizontally. *l.* seven or eight in a dense rosette at the top of the stem, ensiform, 1ft. long, 2in. broad, unarmed, thick, recurved. Southern Arabia, 1894. Plant shortly caulescent. (B. M. 7448.)

A. Monteiroi (Mrs. Monteiro's). *fl.*, perianth dull red, cylindrical, 1in. long; raceme moderately dense, 4in. to 6in. long, 2½in. in diameter; pedicels ascending, ½in. long; peduncle simple, 1½ft. long. *l.* about a dozen in a dense rosette, ensiform, 1ft. long, 1in. broad, gradually tapering to a point, copiously spotted, armed with medium teeth. Stem very short. 1889. (G. C. 1889, vi., p. 523.)

A. penduliflora (pendulous-flowered). *fl.* pale yellow; raceme dense, turned up at the extremity of the pendulous scape. *l.* lax, attenuated, pale green, flattish above, having small marginal prickles. Zanzibar, 1883. A distinct plant, remarkable for the way in which the pendulous scape appears to arise from the base of the back of the leaves. (G. C. 1888, iv., p. 178.)

A. pratensis (meadow-loving).* *fl.*, perianth bright red, tipped green, cylindrical, 1¼in. long; segments lanceolate, united only at the base; pedicels ascending; raceme dense, cylindrical, 6in. to 12in. long; peduncle stout, simple, 1ft. or more long, with copious, empty bracts. *l.* sixty to eighty in a dense rosette, oblong-lanceolate, acuminate, the outer ones 5in. to 6in. long, the inner ones smaller, 1½in. broad at base, margined with red-brown spines. Plant stemless. (B. M. 6705.)

A. Schweinfurthii (Schweinfurth's). *fl.* orange and yellow, disposed in tall, much-branched, many-flowered panicles. *l.* tufted, fleshy, lanceolate, acuminate, remotely toothed on the margins. North-east tropical Africa, 1893. A magnificent species. (B. M. 7667.)

A. striata is the correct name of *A. albocincta.*

A. s. oligospeila (few-stained). This differs from the type in its narrower leaves with a broad white border, taller stem, and more erect habit. 1894.

A. volubilis. *See* **Bowiea volubilis.**

HYBRIDS. A number of Aloë hybrids have been raised within the last few years, of which the following may be mentioned, the names of the parents, where known, being given in parentheses.

A. Bedinghausii (*Gasteria nigricans* and *A. longiaristata*).

A. Beguinii (*Gasteria verrucosa* and *A. longiaristata*).

A.(?) Chludowii (probably *Gasteria scaberrima* and *G. verrucosa*).

A. cyanea (*A. glauca* and *A. incana*).

A. de Laetii (*A. ciliaris* and *A. succotrina*).

A. Derbetzi (*Gasteria acinacifolia* and *A. rubro-cincta*).

A.(?) Holtzei (*Gasteria verrucosa* and *Haworthia Radula*).

A. Hoyeri (*A. serrulata* and *Lomatophyllum borbonicum*).

A.(?) hybrida gloriosa (*Lomatophyllum borbonicum* and *Gasteria maculata*).

A. imbricata (parentage not stated).

A. Lapaixii (*Gasteria maculata* and *A. longiaristata*)

A.(?) Lauchei (*Gasteria pulchra* and *G. scaberrima*).

A. Nowotnyi (*A. longiaristata* and ?).

A.(?) Quehlii (*Gasteria maculata* and *G. picta*).

A. Simoniana (*Gasteria disticha* and *A. longiaristata*).

ALONA belongs to TRIBE *Nolaneæ* of ORD. *Convolvulaceæ.* It embraces half-a-dozen species, confined to Chili.

ALONSOA. SYN. *Hemimeris* (of Humboldt, Bonpland, and Kunth). About a dozen species of this genus have been described; they are found on the Andes of tropical America, from Peru to Mexico. To those given on p. 53, Vol. I., the following should be added:

A. acutifolia (acute-leaved). *fl.* scarlet; anterior lobe of the corolla three or four times as long as the calyx; raceme long and loose. June. *l.* petiolate, ovate-lanceolate, serrated, narrowed at base. Branchlets elongated. Peru, 1790. (R. G. 849.)

A. intermedia (intermediate). A synonym of *A. incisifolia.* SYNS. *Celsia urticæfolia* (B. M. 471), *Hemimeris intermedia* (L. B. C. 1456).

A. linifolia gracilis (slender). The bright orange-scarlet flowers and graceful foliage combine to make this more effective than the type.

ALOYSIA. Bentham and Hooker include this under **Lippia** (which *see*).

ALPINE. Growing on mountains above the timber-line.

ALPINE GARDENS. Below is given a selection of plants which are suitable to the Alpine or rock garden. Many of them are also adapted for the front row of a select border, and the majority are free-growing. Shade-lovers are distinguished by an asterisk (*), and border-plants by a dagger (†).

Acæna microphylla, A. repens, and *A. myriophylla; Acantholimon glumaceum; Achillea rupestris, A. tomentosa, A. umbellata,* and *A. Clavennæ;* †*Adonis vernalis* and *A. pyrenaica;* †*Æthionema coridifolium* and *Æ. saxatile; Ajuga genevensis;* †*Allium* in variety; †*Alyssum montanum, A. saxatile,* and *A. s. compactum; Androsace carnea, A. lanuginosa,* and *A. sarmentosa;* †*Anemone apennina,* †*A. narcissiflora,* **A. Pulsatilla,* †*A. fulgens,* **A. Hepatica,* and **A. vernalis;* †*Antennaria tomentosa,* useful for dry, hot places; *Anthyllis montana;* **Aquilegia glandulosa;* †*Arabis albida, A. procurrens,* and *A. graminifolia;* †*Armeria* in variety for dry places; †*Aster alpinus;* †*Aubrietia deltoidea Campbelli,* †*A. d. græca,* †*A. d. grandiflora,* †*A. d. Hendersoni* and *A. d. Leichtlinii; Auricula* (Alpine) in variety. *Brodiæa,* all the species; *Bulbocodium vernum. Callirhoe involucrata; Calochortus* in variety; *Campanula garganica,* and many other species; *Cerastium tomentosum; Chionodoxa Luciliæ, C. Alleni,* and *C. sardensis; Colchicum,* many species; †*Corydalis lutea,* dry places; *Crocus* species, especially *C. speciosus,* and the winter-flowering kinds; **Cyclamen europæum,* **C. hederæfolium,* and *C. repandum. Daphne Blagayana;* †*Dianthus neglectus,* †*D. cæsius,* and †*D. alpinus;* **Dodecatheon Meadia alba,* **D. Hendersoni,* and *D. Jeffreyi; Draba Mawii* and *D. pyrenaica;* and *Dryas octopetala. Eranthis hyemalis; Erica* in variety; *Erinus alpinus; Erysimum pulchellum,* for dry places; and *Erythronium* in variety. *Fritillaria,* all the small kinds. *Geum montanum;* and *Gnaphalium Leontopodium. Helianthemum,* for very hot, dry banks; and †*Heuchera sanguinea* and *L. s. grandiflora. Iberis correæfolia* and Little Gem; *Ionopsidium acaule;* and *Iris reticulata, I. Bakeriana, I. persica,* and many other species. *Leucoium,* several species; *Linaria alpina* and *L. pallida; Lithospermum graminifolium* and *L. prostratum;* and *Lychnis alpina.* †**Meconopsis cambrica;* †*Muscari,* all the species; *Morisia hypogæa;* and *Myosotis alpestris* and *M. semperflorens. Narcissus minimus,* and other small species and varieties. *Œnothera macrocarpa;* **†Omphalodes verna;* and *Onosma echoides. Phlox,* various kinds; *Phyteuma Scheuchzeri,* and var. *Charmelii* and *P. Michelli;* †*Primula cortusoides,* †*P. denticulata,* †*P. cashmiriana* and *P. marginata;* and †*Prunella grandiflora.* **Ramondia pyrenaica. Saxifraga Sempervivum,* and *Sedum* in variety; **Shortia galacifolia; Silene,* many species; *Soldanella alpina, S. minima, and*

Alpine Gardens—*continued.*

S. montana; and *Statice tatarica.* †*Tiarella cordifolia;* and **Trillium grandiflorum. Veronica prostrata,* and *V. Teucrium. Wahlenbergia tenuifolia. Zauschneria californica.*

ALPINE ROSE APPLE. This is the popular name for a very characteristic gall-like excrescence occurring on the leaves of *Rhododendron hirsutum* and *R. ferrugineum,* two of the most extensively planted of alpine shrubs. They vary considerably as to size and texture, but are of a dirty creamy-white, tinged on the sunny side with a bright pink, and in summer are covered with a kind of bloom. The fungus responsible for the malformation is *Exobasidium Rhododendri,* of the group *Basidiomycetes,* to which belong several of the most destructive tree-fungi in *Agaricus* and *Polyporus,* as well as some of the most useful, considered from an economic point of view—the edible Mushrooms. The galled parts should be removed and burned as soon as they are noticed. They are also called Rhododendron Galls.

ALPINIA. SYNS. *Albina, Buekia, Catimbium, Galanga, Heritiera* (of Retz), *Languas,* and *Martensia.* Including *Hellenia.* ORD. *Scitamineæ.* This genus comprises nearly forty species, natives of tropical and subtropical Asia, Australia, and the Pacific Islands. To those described on p. 54, Vol. I., the following should be added:

A. Allughas (Allughas). *fl.* small, crowded; corolla segments greenish-white, linear-oblong; lip pink, cuneate, distinctly emarginate; panicle erect, 6in. to 12in. long, narrow. February and March. *l.* oblong-lanceolate, 1ft. to 1½ft. long, 3in. to 6in. broad, glossy on both surfaces. Stem 3ft. to 6ft. high. India, &c., 1796. SYN. *Hellenia Allughas* (A. B. R. 501).

A. auriculata (auricled). *fl.* reddish-yellow, smaller than in *A. nutans;* raceme nodding, many-flowered. Spring. *l.* lanceolate, unequal-sided, 2ft. long, reddish-pilose on the margins and on the nerves beneath. Stems pubescent, 10ft. to 12ft. high. Southern Asia, 1814.

Alpinia—*continued.*

A. cærulea (blue). *fl.* reddish-purple, less than 1in. long; thyrse terminal, 4in. to 8in. long, appearing as a simple raceme at first, but most of the peduncles developing two to six flowers. May. *l.* oblong-lanceolate, often above 1ft. long and 2in. broad, acutely acuminate, shortly petiolate above the sheath. Stem 4ft. to 5ft. high. Australia, 1820. SYN. *Hellenia cærulea.*

A. calcarata (spurred). *fl.* medium-sized; corolla segments greenish-white, oblong; lip beautifully variegated with red and yellow on a pale ground, the edges slightly incurved, the base spurred; panicle dense, 3in. to 4in. long. September. *l.* lanceolate, 6in. to 12in. long, 1in. to 2in. broad, acuminate, glossy on both surfaces. Stem slender, 2ft. to 4ft. high. India and China, 1800. (B. R. 141.) SYN. *A. cernua* (B. M. 1900).

A. cernua (drooping). A synonym of *A. calcarata.*

A. magnifica (magnificent). A synonym of *Amomum magnificum.*

FIG. 36. ALSOPHILA ASPERA.

A. malaccensis (Malaccan). *fl.*, corolla segments white, oblong, 1in. long; lip ovate, emarginate, 1½in. to 2in. long, the margins pale, the centre beautifully variegated with red and yellow; raceme erect, simple, 6in. to 12in. long. April. *l.* 2ft. to 3ft. long, oblong-lanceolate, pubescent beneath. Stem 6ft. to 10ft. high. India, &c., 1799. (B. R. 328.)

A. officinarum (officinal). *fl.* white, sessile in a simple spike; lip oblong, obtuse, entire or emarginate, the disk nerved with blood-red. Winter. *l.* narrow-lanceolate, caudate-acuminate, highly glabrous, narrowed to a sessile sheath at base; sheath elongated, produced in an erect ligule. Stem tuberous at base, erect, leafy. South China, 1883. (B. M. 6995.)

A. pumila (dwarf). *fl.* about 1in. long, in a short, rather dense spike, about two to each bract, sessile, sub-erect; calyx bright red; corolla pink, the lip recurved or almost revolute; scape or flowering stem radical, about 2in. long. April. *l.* two or three together, erect from the rootstock, 4in. to 6in. long, elliptic or elliptic-lanceolate, acuminate, green, with whitish stripes, pale green beneath; petioles 2in. to 4in. long, sheathing below. Lo-fan-Shan Mountains, China, 1883. (B. M. 6832.)

Alpinia—*continued.*

A. zingiberina (Zingiber-like). *fl.* erect, 1in. long; calyx about ¼in. long; lateral and dorsal lobes of the corolla pale green; lip white, veined crimson, broadly ovate, obtuse; panicle nearly erect, 10in. to 12in. long. July. *l.* 10in. to 12in. long, 3in. broad, oblanceolate-oblong, acute and abruptly cuspidate, glabrous. Stems 4ft. to 5ft. high. Rhizomes 1in. in diameter, resembling ginger. Siam, 1824. (B. M. 6944.)

ALSEUOSMIA (from *alsos*, a grove, and *euosmia*, a grateful odour; the powerful fragrance of the flowers scents the woods in their native haunts). ORD. *Caprifoliaceæ*. A small genus (four species) of highly glabrous, polymorphous, greenhouse shrubs, confined to New Zealand. Flowers greenish or reddish, axillary, solitary or fascicled, sweetly scented; calyx tube ovoid, the limb four- or five-lobed; corolla tubular or funnel-shaped, the tube elongated, the limb of four or five equal, spreading lobes; stamens four or five; pedicels bracteolate at base. Fruit a purple, ovoid, many-seeded berry. Leaves alternate, rarely opposite, petiolate, membranous, linear-lanceolate, ovate, or rhomboid, entire or toothed, with minute tufts of hairs in the axils of the nerves beneath. *A. macrophylla* is the only species introduced to cultivation. It thrives in well-drained, peaty soil, and likes plenty of air and light. Propagated by cuttings of half-ripened growths, inserted under a bell glass.

A. macrophylla (large-leaved).* *fl.* in small, axillary clusters, drooping; corolla dull red, or creamy-white with dull red streaks, the tube cylindric, funnel-shaped above, the lobes ovate, recurved, toothed. February. *l.* 3in. to 6in. long, elliptic-lanceolate or oblanceolate, acute, entire or serrated, narrowed into petioles ¼in. to ½in. long. *h.* 6ft. to 10ft. 1824. Plant glabrous. (B. M. 6951.)

ALSINE. Included under **Arenaria** (which *see*).

ALSOMITRA (said to be derived from *alsos*, a grove, and *mitra*, a mitre; probably in allusion to the plant crowning the trees). ORD. *Cucurbitaceæ*. A small genus (three to five species) of large, stove, climbing shrubs, extending from Nepaul through Malaya to North Australia. Flowers white, small, dicœcious, in compound panicles; calyx and corolla both rotate and five-parted; stamens five. Fruit often large, elongated. Leaves having three oblong, entire leaflets. Tendrils simple or bifid. Only one of the species has been introduced. It thrives in a rich loamy compost and requires an abundance of water during the period of growth. It may be propagated by seeds, or by cuttings inserted over bottom-heat.

FIG. 37. ALSOPHILA ATROVIRENS.

A. sarcophylla (fleshy-leaved). *fl.* very numerous, in nodding panicles. Winter. *fr.* 1¾in. long, ⅝in. broad. *l.* very fleshy, 2½in. long, 1⅜in. broad, obtuse; petiolules scarcely ¼in. long. Birma, 1870. SYN. *Zanonia sarcophylla.*

ALSOPHILA. Including *Lophosorus*, *Trichopteris*, and *Trichosorus*. Upwards of ninety species have been referred to this genus; they are found in Australia, New Zealand, South America, India, tropical Africa, Eastern Asia, &c.

Nearly all the Alsophilas are found inhabiting moist glens, and have a tendency to assume large proportions. Some of them, such as *A. australis*, *A. conjugata*, *A. contaminans*, *A. Cooperi*, *A. Leichardtiana*, *A. pycnocarpa*, &c., are frequently seen in their native habitats with stems varying between 20ft. and 30ft. in height; while

Alsophila—*continued.*

A. excelsa, perhaps the most rapid grower of all, is said to have a trunk or stem between 60ft. and 80ft. high.

To induce them to make good growth under artificial conditions, it is necessary that the Alsophilas, as well as all other Tree-Ferns, should have an abundant supply of water during the summer, but taking care to moderate the sprinklings during the winter—without, however, suspending them altogether in any case. Occasional waterings with weak liquid manure are beneficial to them, especially in the spring when the new fronds are unfolding. Although Alsophilas grow well in a light conservatory, where they produce fronds of a hardy and very substantial texture, it is under the combined influences of shade and moisture that their most vigorous growth is produced; they should therefore be sufficiently shaded to prevent the sun from burning the fronds as they unfold, as well as to keep them from being discoloured when fully developed. As is the case with all arborescent Ferns, very little pot room will suffice for Alsophilas. They should be potted, tubbed, or, better still, planted out in the houses, in a compost of three-parts peat, one part fibrous loam, and one part sand as coarse as procurable: in this they will grow luxuriantly for years without requiring further attention than constant moistening.

A. capensis, *A. Van Geertii*, and perhaps a few other kinds, produce on their stems young growths, from which they can be propagated; but Alsophilas are usually increased from spores, which are abundantly produced and germinate freely under warm treatment.

A. excelsa is essentially a decorative Fern, growing larger and quicker than *A. australis*; young plants of it are extensively employed for indoor decoration, as very little time is required from the seedling state to get them sufficiently strong to be useful for that purpose; but those home-raised seedlings which are kept and grown on, soon form short stems or trunks, producing fine heads of massive yet gracefully-arching fronds, often reaching 4ft. in length. When in that state, *A. excelsa* is a most effective plant for sub-tropical gardening.

Although very scarce in cultivation, *A. pruinata* deserves every attention, if only on account of its distinctive and ornamental characters, for its fronds, of a particularly elegant habit, are quite as silvery underneath as those of the better-known *Cyathea dealbata*; while the stem or trunk from which they are produced, and which under cultivation seldom attains large proportions, usually forms several crowns or heads, and by the division of these the plant can be increased. To those described on pp. 54-6, Vol. I., the following should be added:

FIG. 38. ALSOPHILA PYCNOCARPA.

A. Andersoni (Anderson's). *fronds* large, tripinnatifid, rough on their under-surface; rachis dark chestnut-colour; pinnæ oblong-lanceolate, 1½ft. to 2ft. long; pinnules numerous, almost stalkless, cut down to a narrow wing 4in. to 6in. long and 1in. broad; ultimate segments closely set, spear-shaped, bluntish, about ¼in. broad, distinctly toothed, their ribs densely bristly. *sori* very small, inframedial. Sikkim. A distinct, stove species.

A. aspera (rough). An illustration of this fine West Indian species is given in Fig. 36.

A. atrovirens (dark green).* *sti.* about equal to the fronds, stout, and slightly scaly. *fronds* large, tripinnatifid; pinnæ spear-shaped, 9in. to 15in. long, 3in. to 4in. broad; pinnules cut down half-way to the midrib; segments entire, ¼in. broad. *sori* small, numerous, medial. South Brazil, 1883. Stove. See Fig. 37.

Alsophila—*continued.*

A. a. Keriana (Ker's). *sti.* 6in. to 8in. long, dull brown, muricated. *fronds* oblong-lanceolate, bipinnate, 1¼in. to 1½in. long, 6in. broad, firm, pilose on the main veins beneath; lower pinnæ 3in. to 4in. long, cut down to the rachis. 1884.

A. capensis (Cape). A synonym of *Hemitelia capensis.*

A. Colensoi (Colenso's). *cau.* 4ft. to 5ft. high, spineless. *sti.* short, densely clothed with silvery-white scales and smaller brown ones. *fronds* slightly hairy, 2ft. to 4ft. long, 1ft. or more broad; primary pinnæ 12in. to 14in. long, acuminate; pinnules 2in. long and ¼in. broad, deeply pinnatifid; ultimate segments strongly serrated. *sori* small, round, nearer the midrib than the margin. New Zealand and Otago. Greenhouse.

A. crinita (hairy).* *sti.* strongly muricate, of a peculiar brown colour. *fronds* when young densely covered with long, chaffy hairs of a light colour; primary pinnæ 2ft. long, 10in. broad; pinnules sessile, cut nearly to the midrib; ultimate lobes sickle-shaped, narrow, the margins recurved and toothed. *sori* covering the whole under-side of the lobes and mixed with scales. Java, Ceylon, &c. A singular and very shaggy-looking, stove species.

A. infesta phalerata (white). *fronds* having the segments ¼in. broad, close, blunt, entire. *sori* larger than in other forms, confined to the lower veins.

A. latebrosa (dark, shady). *sti.* prickly at base, muricated upwards, dark mahogany-brown. *fronds* bipinnate; pinnæ 1ft. to 2ft. long, 6in. to 8in. broad, acuminate; pinnules lanceolate, acuminate, 3in. to 4in. long, ½in. broad, cut down nearly to the rachis into numerous narrow, blunt, slightly-toothed lobes, dark green and smooth above, slightly hairy and scaly beneath. *sori* elevated and conspicuous, often occupying the lower two-thirds of the fertile lobes. India, &c. Stove. According to Beddome, this is the commonest Tree Fern throughout India.

A. Marshalliana (Marshall's). *fronds* of a dark, shining green; pinnæ very much crisped and gracefully waved. 1894. A plant of dwarf habit.

A. phalerata (white). A variety of *A. infesta.*

A. podophylla (footstalk-fronded). *sti.* spiny, and, as well as the rachis, purplish-brown. *fronds* ample, somewhat leathery; pinnæ 2ft. or more in length, pinnatifid at their summit; pinnules distinctly stalked, 4in. to 8in. long, ½in. to 1in. broad, variable, being either sub-hastate, cordate, or truncate at base, sometimes either toothed towards their tip, entire, slightly lobed, or more or less deeply cut to the midrib. *sori* in a single row parallel with the primary vein of the fertile pinnules. Chusan and Hong Kong, 1881. Greenhouse.

A. pycnocarpa (densely-fruited). *cau.* thorny, seldom exceeding 6ft. in height. *fronds* ample, coriaceous, bipinnate; pinnæ borne on short, articulated stalks; pinnules nearly stalkless, dented at the base, blunt at the tip, dark green on both surfaces. *sori* set so closely together in two rows as to be almost contiguous on the fertile pinnules. Peru. Stove. See Fig. 38.

A. tomentosa (downy). *sti.* and main rachis palish brown, strongly muricated. *fronds* coriaceous, dark green above; pinnules sessile, divided nearly to the midrib into narrow-oblong lobes which are conspicuously cobwebby on their under-side with small, white, ragged, woolly scales. *sori* covering the whole under-surface. Java and Formosa. Stove. This resembles *A. crinita*, but is scarcely hairy in any part.

A. truncata (truncate). *fronds* ample, tripinnate, with a glossy, dark purple rachis; pinnæ 10in. to 15in. long, 4in. to 5in. broad, oblong, acuminate; pinnules very small, stalkless, set at a little distance apart, truncate at base, firm, coriaceous, bright green above, paler beneath, the margins slightly lobed and recurved. *sori* small, dark orange-colour, close to the midrib of the fertile pinnules. Fiji and Samoa. A distinct, stove species.

A. Van Geertii (Van Geert's). A garden name for *Cyathea mexicana.*

ALSTRÖMERIA. According to J. G. Baker, this genus camprises about forty-four species, confined to Brazil and Chili.

For affording cut-flower material, such species as *A. aurantiaca*, *A. chilensis*, and *A. psittacina*, are highly esteemed. Many cultivators experience difficulty in growing these useful plants. The chief point to observe is in the planting. This should take place in October, inserting the roots from 6in. to 8in. deep. If, as is commonly done, they are planted at, say, a depth of 3in. or 4in., they are almost certain to be killed if severe weather sets in. Plenty of water when growing, and a summer mulching, will also be found beneficial.

To the species, &c., described on p. 58, Vol. I., the following should be added. Several plants formerly included here are now classed under **Bomarea.**

A. aurea (golden) (B. M. 3350). A synonym of *A. aurantiaca* (B. R. 1843; S. B. F. G. ser. ii. 205).

A. bicolor (two-coloured). A synonym of *A. Ligtu pulchra.*

Alströmeria—*continued.*

A. brasiliensis (Brazilian). *fl.*, perianth reddish-yellow, 1¼in. long, the inner segments spotted with brown; umbel of five one- to three-flowered rays. *l.* of the fertile stem linear, erecto-patent, 3in. to 4in. long; those of the sterile stem lanceolate, 3in. to 4in. long, ¾in. broad, mainly confined to the upper half. Sterile stem 2ft. long. Central Brazil.

A. densiflora. The correct name is *Bomarea tomentosa.*

A. hæmantha (blood-coloured). The correct name of *A. Simsii* (B. G. 264; S. B. F. G. ser. ii. 158). SYN. *A. pulchella* of Sims (B. M. 2354; B. R. 1008; H. E. F. 64).

A. h. Simsii (Sims's blood-flowered). A synonym of *A. Simsii.*

A. Hookeri, of Loddiges. A form of *A. Ligtu.*

A. Ligtu (Ligtu). *fl.* whitish, pale lilac, or pale red, obliquely streaked with purple; perianth about 1½in. long, the outer segments obovate-unguiculate, the inner ones narrower and more acute; umbel three- to eight-rayed. *l.* twenty to thirty, thin, linear or lanceolate, the largest 2in. to 3in. long. Stem 1½ft. to 2ft. long. Chili. (B. R. 1839, t 3). *A. Hookeri* (L. B. C. 1272), *A. pallida* (B. M. 3040), and *A. rosea* (H. E. F. 221), are forms of this species.

A. L. pulchra. The correct name of *A. pulchra* (B. M. 2421). SYN. *A. bicolor* (H. E. F. 65; L. B. C. 1147).

A. Ligtu, of Curtis. A synonym of *A. caryophyllæa.*

A. Neillii (Neill's). A form of *A. spathulata.*

A. oculata (eyed). A synonym of *Bomarea Salsilla.*

A. ovata (ovate). A synonym of *Bomarea edulis ovata.*

A. pallida (pale). A form of *A. Ligtu.*

A. pulchella, of Linnæus, is the correct name of *A. psittacina*, which is quite distinct from *A. Simsii* (*hæmantha*).

A. rosea, of Hooker, is a form of *A. Ligtu.*

A. Salsilla (Salsilla), of Gawler. A synonym of *Bomarea edulis.*

A. spathulata (spathulate). *fl.* reddish, few in a simple umbel; perianth 1in. to 1½in. long, the outer segments obovate-unguiculate, the inner ones acute. *l.* crowded in the upper part of the stem, oblong-spathulate, thick, crisped, and scarious at the edges, 1in. to 2in. long, ¼in. to ¾in. broad. Stem 6in. to 12in. long. Andes of Chili. *A. Neillii* (B. M. 3105) is "probably a robust cultivated condition" of this species (Baker).

ALTERNANTHERA. Leaves opposite, sessile or petiolate, obovate, oblong, or linear, entire or obscurely toothed. To the species described on p. 59, Vol. I., the following should be added:

A. chromatella (yellowish). This is probably identical with *A. paronychioides major aurea.*

A. sessilis (stalkless). *l.* 1in. to 3in. long, linear, oblong, lanceolate, or elliptic, obtuse or slightly acute, rather fleshy, sometimes obscurely denticulate. Branches many, 3in. to 18in. long, glabrous, prostrate or ascending. India, 1778. Biennial.

A. s. amœna (pleasing). In this variety the upper leaves are reddish. (I. H. 1865, t. 447.)

A. spathulata (spoon-shaped). A handsome form, having spathulate leaves varying in colour from green, through pink, to dark brown. 1865. (I. H. 1865, t. 445.)

ALTHÆA. About a dozen species, natives of the temperate regions of the globe, form this genus, two of them—*A. hirsuta* and *A. officinalis*—being natives of Britain. To the species described on p. 59, Vol. I., the following should be added:

A. rosea is not a native of China, as stated in Vol. I., but of the Orient.

A. sulphurea (sulphur-coloured).* *fl.* sulphur-yellow, on thick, solitary, tomentose peduncles; petals more than twice as long as the calyx, ciliated to the claws; raceme short, lax, few-flowered. Summer. *l.* thick, ovate, obtuse, crenulate, entire or very slightly repand-trilobed, the lower ones obtuse and rounded at base, the upper ones slightly acute and cuneate at base. Stems erect, rigid, simple or slightly branched. Persia, &c. Plant shrubby at base.

ALTINGIACEÆ. Included under **Hamamelideæ** (which *see*).

ALTITUDE. Elevation or altitude has a great influence on all vegetation. The higher the altitude the lower the temperature. At the same time, this does not prove that the less the elevation is above sea-level the warmer and more suited is the place for plant-life. An altitude of 500ft. above sea-level is considered by some authorities to be best for hardy fruit-culture; while in this country ordinary timber grown at a moderate elevation is more durable than the same kind grown nearer the sea-level.

ALTORA. A synonym of **Cluytia** (which *see*).

ALUM. *See* **Symphytum officinale.**

ALYSSUM. Including *Anodontea*, *Berteroa*, *Meniocus*, *Odontarrhena*, *Psilonema*, and *Schivereckia*. This genus comprises from eighty to ninety species, natives of Asia Minor, South Europe, Persia, North Africa, the Caucasus, and Siberia, *A. calycinum* and *A. maritimum* being natives of the British Islands. To those described on pp. 60-1, Vol. I., the following should be added:

A. gemonense sulphureum (sulphur-coloured). This is the most distinct in colour of all the Alyssums, being of a nice pale lemon.

A. pyrenaicum (Pyrenean). *fl.* white, with chocolate-coloured anthers. June to August. *l.* obovate, attenuated at base, cano-tomentose. Stem shrubby; branches unarmed. Habit dwarf, tufted.

A. saxatile citrinum (citron-yellow). This has lemon-yellow flowers.

A. s. flore-pleno (double flowered).* This is a double-flowered form of considerable merit. The flowers are bright yellow, and borne in sprays.

A. s. nanum compactum (dwarf, compact).* A dwarf variety, forming dense tufts, composed of a great number of short stalks producing yellow flowers much more freely than the type. June to August. An excellent plant for borders or for carpet-bedding, popularly known as Gold Dust.

A. spinosum (spiny). The correct name of *Kœniga spinosa*.

A. utriculatum (bladder-like). A synonym of *Vesicaria græca*.

ALYXIA (said to be the native Indian name of one of the species). SYN. *Gynopogon*. ORD. *Apocynaceæ*. A genus embracing about thirty species of stove, often glabrous shrubs, inhabiting Eastern tropical Asia, the Malayan Archipelago, Ceylon, Madagascar, tropical Australia, and the Pacific Islands. Flowers rather small, twin or cymose; calyx five-parted, glandless; corolla salver-shaped, with a cylindrical tube and five twisted lobes; stamens included. Leaves whorled in threes or fours, or rarely opposite, coriaceous, shining, penniveined. The best-known species are here described. They thrive in a mixture of sandy loam and a little peat. Cuttings of ripened wood will root freely if inserted in pots of sand, under glass, and plunged in heat.

A. bracteolosa (slightly bracteate). *fl.* pale yellow, with a long tube; cymes axillary, many-flowered, shortly pedunculate. *l.* in threes, oblong or sub-lanceolate, obtuse or acuminate at apex, rounded or acute at base. Fiji, 1887. Climber.

A. daphnoides (Daphne-like). *fl.* yellowish-white, sessile, axillary and terminal, solitary. April. *l.* in fours, obovate-oblong, elliptic, or rhomboid, obtuse, shining, ¼in. to ¾in. long. *h.* 4ft. Norfolk Island, 1831. (B. M. 3513.)

A. ruscifolia (Butcher's-Broom-leaved). *fl.* white, small, sessile, in sessile, terminal heads. July. *l.* whorled, broadly ovate-elliptic to narrow-lanceolate, acute, with a short, pungent point, ¾in. to 1¼in. long, shortly petiolate, the margins recurved or revolute. Australia, 1820. A tall, handsome shrub. (B. M. 3312; L. B. C. 1811.)

ALZATEA (named after Alzaty, a Spanish naturalist). ORD. *Celastrineæ*. A monotypic genus. The species, *A. verticillata*, is a greenhouse, evergreen, highly glabrous tree, with yellowish flowers, opposite whorled leaves, and purple branches. It was introduced in 1824, but is probably lost to cultivation.

AMALIAS. A synonym of **Lælia** (which *see*).

AMARABOYA (the native name). ORD. *Melastomaceæ*. A small genus (three species) of erect, glabrous, stove or greenhouse, evergreen shrubs, natives of Colombia. Flowers showy, cymose; petals usually six, cordate; stamens twelve to fifteen. Leaves large, opposite, sessile, with three very prominent nerves, green above, reddish-carmine beneath. Branches as thick as the thumb, bluntly four-angled. The species will probably thrive under the same treatment as that recommended for **Pleroma** (which *see*).

A. amabilis (lovely). *fl.* white, margined with carmine, large; petals broad; style red, elongated; umbels terminal. *l.* 10in. to 12in. long, 8in. broad, opposite, elliptic, canescent beneath, the three nerves brownish or reddish. Stems terete, purplish. 1837. (I. H. ser. v. 9.)

Amaraboya—*continued.*

A. princeps (foremost). *fl.* of a uniform bright carmine, very showy; petals usually six, broadly cordate; stamens white; cymes terminal, few-flowered; peduncles stout. *l.* elliptic, sessile, apiculate, 7in. to 10in. long, 3in. to 5in. broad, green above, reddish-brown beneath. 1887. (I. H. ser. v. 4.)

A. splendida (splendid). *fl.* 6½in. across, very beautiful; petals sub-triangular, 3in. long, nearly 2½in. broad, at first reddish-pink, becoming white in the lower part; stamens yellowish; style red, elongated. *l.* very large, ovate-oblong, green above, coppery-pink with three red nerves beneath. 1886. A gorgeous plant. (I. H. ser. v. 34.)

AMARALIA. This name is kept up by the authors of the "Genera Plantarum"; but according to the "Index Kewensis," the older name for the genus is **Sherbournia** (which *see*).

AMARANTUS [also spelt *Amaranthus*]. Including *Euxolus*. About forty-five species have been described, but many of these have no claim to specific rank; they are broadly distributed in both Old and New Worlds. Leaves small or minute. To the species, &c., described on p. 61, Vol. I., the following should be added:

A. atropurpureus nanus (dark purple, dwarf). A form of *A. caudatus*.

A. caudatus atropurpureus nanus. *fl.* in rather long, erect, cylindrical spikes. *l.* of a dark reddish-brown. *h.* about 1½ft.

A. c. gibbosus (swollen). *fl.* red, clustered in groups about the size of a nut and more or less spaced. Plant smaller and slenderer than the type, and singular in appearance.

A. Dussii (Duss's). *fl.* and *l.* brightly coloured. West Indies, 1896. A handsome, hardy annual, probably a variety of *A. spinosus*.

A. paniculatus (panicled), The correct name of *A. speciosus*. (B. M. 2227).

A. sanguineus nanus (dwarf). A dwarf garden variety, with leaves of an intense red.

A. spinosus (spiny). *fl.* greenish; terminal spike elongated, bending, the lower axillary ones short and roundish. July to October. *l.* ovate or ovate-oblong, obtuse or emarginate, long-petiolate, often blotched with purple, spiny in the axils. Stem 1ft. to 3ft. high, stout, succulent, often purplish. United States.

A. splendens (splendid). Joseph's Coat. *l.* regularly variegated with brown, dark green, red, and golden-yellow. Branches furnished at the extremities with loose panicles of brilliant red flowers, surrounded by leaves of the same tint. Stem vigorous, erect, and much-branched. *h.* 3ft. 1885. A garden form.

A. superbus (superb). *l.* elliptic, blood-red on the upper surface, crimson beneath. 1896. Half-hardy. Probably a variety of *A. melancholicus*. (I. H. 1896, p. 141, f. 15.)

AMARYLLIS. As mentioned on p. 62, Vol. I., the species formerly included here are now classed under various genera. The following synonyms and varieties may be noted:

A. aurea (golden). A synonym of *Lycoris aurea*.

A. Belladonna. There are numerous handsome varieties in cultivation, including *alba*, *carminea*, *magnifica*, *O'Brieni*, and *stenopetala*.

A. B. blanda (beautiful).* *fl.* lighter in colour, larger, and opening wider than in the type; segments 3in. to 4in. long, 1in. to 1¼in. broad. *l.* more sheathing at the base, longer, and broader. (B. M. 1450, under name of *A. blanda*.)

A. ciliaris (ciliated). A synonym of *Buphane ciliaris*.

A. citrina (citron-coloured). A synonym of *Sternbergia colchiciflora*.

A. crispa (curled). A synonym of *Hessea crispa*.

A. disticha (two-ranked). A synonym of *Buphane disticha*.

A. hyacinthina (Hyacinth-like). A synonym of *Griffinia hyacinthina*.

A. stellaris (star-like). A synonym of *Hessea stellaris*.

A. tatarica (Tartary). A synonym of *Ixiolirion tataricum*.

AMASONIA. The correct name of *A. punicea* (SYN. *Taligalea punicea*) is *A. calycina* (B. M. 6915). To the species described on p. 62, Vol. I., the following should be added:

A. erecta (erect). *fl.* white, marked with pink on the inside of the segments, hairy, drooping, 1in. long, disposed in a racemiform, elongated, terminal panicle; bracts scarlet, golden at base, subtending the flowers, ovate or nearly orbicular, serrulate. July. *l.* alternate and somewhat whorled, 4in. to

Amasonia—*continued.*

6in. long, crenate-serrate, oblong, dark green above, pale beneath; petioles 2in. to 3in. long. South America. A small, slender, sparingly-branched shrub.

A. e. latebracteata (broad-bracted). *fl.*, bracts orbicular, 1in. long, shortly petiolate, remotely denticulate. 1895. (B. M. 7445.)

AMATUNGULA. *See* **Carissa grandiflora.**

AMBERBOA MOSCHATA. A synonym of **Centaurea moschata** (which *see*).

AMBLOSTOMA (from *amblos*, blunt, and *stoma*, a mouth; in allusion to the form of the pollinia). ORD. *Orchideæ*. A small genus (three species) of stove, epiphytal Orchids, one Brazilian, another Peruvian, and the third Bolivian. Flowers small, shortly pedicellate, racemose, disposed in a slender, rigid panicle. Leaves narrow. *A. cernuum* (SYN. *A. tridactylum*) is in cultivation at Kew, but is not often seen elsewhere.

AMBLYANTHERA. A synonym of **Mandevilla** (which *see*).

AMBLYGLOTTIS. A synonym of **Calanthe** (which *see*).

AMBLYOLEPIS. Included under **Helenium** (which *see*).

AMBROSIA BEETLES. *See* **Apple-Bark Beetle.**

AMECHANIA. A synonym of **Agarista** (which *see*).

AMELANCHIER. SYN. *Aronia* (in part). The four species of this genus are natives of South Europe, Asia Minor, Japan, and North America. To the species described on p. 63, Vol. I., the following should be added. *See also* **Peraphyllum.**

A. alnifolia (Alder-leaved). Dwarf June Berry. *fl.* numerous, in dense racemes. *fr.* dark purple, globose, ¼in. in diameter. *l.* roundish, blunt or notched at both ends, serrated towards the apex. *h.* 6ft. to 8ft. North-west America, 1883. An ornamental shrub. (G. and F. 1888, i., p. 185, f. 34.)

A. Botryapium (Botryapium). A synonym of *A. canadensis*.

A. canadensis oblongifolia (oblong-leaved). *fl.* white, shortly-racemose, borne in great profusion. The last variety to blossom.

A. oligocarpa (few-fruited). *fl.* white, ½in. in diameter, on long pedicels, solitary or in pairs, rarely three or four in a raceme. *fr.* dark bluish-purple, obovate or shortly oblong. *l.* oblong, acute, crenulate, glabrous. *h.* 2ft. to 4ft. Eastern United States, 1883. A bushy tree. (G. and F. 1888, i., pp. 245-7, f. 41.)

AMERICAN BLACKBERRY. *See* **Rubus villosus.**

AMERICAN BLIGHT, or WOOLLY APHIS (*Schizoneura lanigera*). Despite the greater attention now given to fruit-trees by the cultivator, this insect continues to increase. And little wonder, considering how readily the white cottony "particles," together with the insects, are wafted by the wind, and the rapid methods of increase. The greatest number are to be found in neglected orchards, where trees are left for years "to take care of themselves." They are not, however, confined to such, for new plantations of young trees are also attacked. The insects generally take up a position in the crevices of the bark, on shoots both large and small, as well as on the foliage. The bark in bad attacks splits, and soft spongy growths are present. After a while these quite break down, exposing a vital part of the tree to injurious wound fungi. Hence it is that canker caused by *Nectria ditissima* is so frequently found. Woolly Aphides also attack the roots, and cause considerable injury if they are allowed to go on unmolested. At one time it was thought that the root-feeding specimens were somewhat different from those infesting the portions of the tree above ground. Such, however, is not the case. Roots attacked by the pests are frequently covered by large warty growths.

The insects' presence above ground is readily told by the woolly material which issues from the dorsal pores. This serves as a shelter for the pests, and especially

American Blight, or Woolly Aphis—*continued.*

stands them in good stead in winter. Woolly Aphides are brown in colour with the exception of the wingless egg-producing, dingy-yellow females, which are produced by the winged females. The eggs are deposited singly in cracks and crevices of the tree; but the insects rely not alone on this means of increasing, for there are individuals which as larvæ live through the winter, and then produce their young alive. It is these which one finds when dressing the trees in winter.

It is not an easy matter to deal with Woolly Aphides except on low-growing trees. The best insecticide in summer is Calvert's Carbolic Soft Soap (1oz. to 1gall. of soft water). This should be made warm, and directed with some force with a garden-engine. Another good recipe is soluble petroleum, 1 wineglassful; water (warm), 1gall.; soft soap, 1lb.; with the addition of a handful of lime. Care must, however, be taken to keep the trees free from extraneous growth like lichen. To prevent this, and also to kill the Aphides, some cultivators spray on (in *winter only*) the following mixture: ½lb. caustic soda (Greenbank's 98 per cent.) and ½lb. crude potash dissolved in 5gall. of water. This must be used with care, or the hands will suffer. Stout gloves should always be used. So much for the tree above ground. For the root-feeders a wash made with the carbolic soft soap above recommended will prove beneficial, first removing the soil. This, too, should be performed in winter. All prunings should be carefully taken away and burnt. *See* also p. 63, Vol. I.

AMERICAN KIDNEY-BEAN TREE. *See* **Wistaria frutescens.**

AMERIMNON. Bentham and Hooker include this under **Dalbergia** (which *see*).

AMETHYSTEA (from *amethystos*, the amethyst; in allusion to the colour of the blossoms). ORD. *Labiatæ*. A monotypic genus. This species, *A. cærulea* (B. M. 2448), is a hardy, erect annual. For culture, *see* **Annuals.**

A. cærula (blue). *fl.* blue, small, cymose; corolla scarcely exceeding the calyx; cymes pedunculate, lax, racemosely panicled. July. *l.* petiolate, three- to five-parted; segments oblong-lanceolate, incised-toothed; floral ones smaller. *h.* 1ft. Temperate Asia, 1759. (B. M. 2448.)

AMIANTHEMUM. Included under **Zygadenus** (which *see*).

AMICIA. This genus embraces four species, natives of the Andes, from Bolivia to Mexico. Flowers yellow, rather large, in short, axillary racemes, rarely solitary; bracts and bracteoles broad. Leaves abruptly pinnate; leaflets usually two pairs, obovate or obcordate, exstipellate; stipules usually large, deciduous.

AMISCHOTOLYPE. A synonym of **Forrestia** (which *see*).

AMMOCHARIS (from *ammos*, sand, and *charis*, love; the species are found in sandy ground). SYN. *Palinetes*. ORD. *Amaryllideæ*. A monotypic genus. The species is a greenhouse, bulbous plant, requiring similar culture to **Brunsvigia** (which *see*).

A. falcata (sickle-shaped). *fl.* bright red, fragrant, twenty to forty in an umbel; perianth funnel-shaped, with a stout, cylindrical tube ¼in. long, and six equal, ascending, oblanceolate-unguiculate segments; peduncle lateral, 6in. to 12in. long. Winter. *l.* bifarious, lorate, spreading, 1ft. to 2ft. long, produced before the flowers. Bulb 6in. to 9in. in diameter. South Africa. SYNS. *Amaryllis coranica* (B. R. 139 and 1219, var. *pallida*), *Brunsvigia falcata*.

AMMODENDRON. *Sophora* is not synonymous with this genus. *S. bifolia* is a synonym of *A. Sieversii*

AMMOGETON. Included under *Troximon*, the correct name of *A. scorzoneræfolium* being **T. glaucum dasycephalum** (which *see*).

AMMOLIRION. A synonym of **Eremurus** (which *see*).

AMMOPHILA ARUNDINACEA. A synonym of **Psamma arenaria** (which *see*).

AMOMUM. About fifty species are included in this genus; they are mostly found in tropical Africa and Asia, but extend as far as Australia and the Pacific Islands. To those described on pp. 64-5, Vol. I., the following should be added:

A. Clusii (Clusius'). *fl.* golden-yellow; lateral lobes spreading, lanceolate-subulate, the dorsal one longer; lip broadly obovate-spathulate, the margins entire; scape radical, few-flowered. December. *l.* linear- or oblong-lanceolate, long-acuminate. Fernando Po. (B. M. 5250.)

A. C. purpureum (purple). The correct name of *A. Danielli.*

A. hemisphæricum (hemispherical). *fl.* green, with the exception of the lip, which is reddish-brown margined with yellow, borne in a dense, globose head; peduncle short, rising from the rootstock among the stems. *l.* distichous, oblong-lanceolate, 1ft. or more in length, 3in. broad. Stems 10ft. to 12ft. high. Japan, 1893. Greenhouse. (B. M. 7592.)

A. magnificum (magnificent). *fl.* deep purplish-red, shorter than the bracts, cylindrical; bracts deep rose-red, narrowly margined with white, the outer ones often reflexed, 3in. to 4in. long; scape 5ft. to 6ft. high, leafless. July and August. *l.* few, oblong, acute. Stems 10ft. to 12ft. high, rigid. Mauritius, 1830. SYN. *Alpinia magnifica* (B. M. 3192).

A. Melegueta minor (lesser). *fl.*, lip orbicular; bracts appressed, convolute. Western Tropical Africa, 1869. Plant smaller than the type in all its parts. (B. M. 5937.)

AMOORA (*Amoor* is the Bengali name). SYNS. *Andersonia, Aphanamixis.* ORD. *Meliaceæ.* A genus embracing about ten species of stove, evergreen, often tall shrubs, natives of tropical and sub-tropical Asia and Australia. Flowers small, polygamo-dicœcious, the males paniculate, the females often spicate or racemose; inflorescence axillary. Leaves imparipinnate. Two species —*A. cucullata* and *A. Rohituka*—have been introduced, but they are probably lost to cultivation.

AMORPHOPHALLUS. Bentham and Hooker include hereunder *Brachyspatha, Conophallus, Corynophallus, Proteinophallus,* and *Tapeinophallus;* but *Brachyspatha* and *Corynophallus* have been kept distinct in Vol. I. This genus comprises about twenty-five species, inhabiting tropical Asia and Africa, the Malayan Archipelago, Australia, and the Pacific Islands.

These curious plants should not be planted out until all danger of severe frost is past. April is usually early enough, and 6in. is none too great a depth at which to insert the roots. *A. Rivieri*, an illustration of which appears in Vol. I., is frequently potted up and used as a room plant; its stout white-spotted scape, rose-marbled leaf stalk, and large leaves, make a very effective whole. Equally decorative are they as foliage plants in the greenhouse.

To those described on p. 65, Vol. I., the following should be added:

A. Afzelii (Afzelius'). A synonym of *Corynophallus Afzelii.*

A. bulbifer (bulb-bearing). *fl.*, spathe dirty green, spotted with rose on the outside, red within but yellowish-green towards the apex, about 5in. long; spadix green and pink; peduncle 10in. to 12in. long. *l.* tripedatisect, bearing tubers at the ramifications of the ribs; primary segments 8in. to 12in. long; petiole 3ft. long. Tuber sub-globose. India. (R. G. 1871, t. 688.) SYN. *Arum bulbiferum* (B. M. 2072, 2503).

A. dubius (doubtful). *fl.*, spathe tube green, 3in. long, the limb ovate, 3in. to 5in. in diameter, waved, the disk dark purple with a green border; spadix 4in. long, the appendage chestnut-brown, 1½in. in diameter; peduncle very short. *l.* one or two, 1ft. to 3ft. broad; segments simple or forked; leaflets oblong, acute. Malabar and Ceylon, 1857. (B. M. 5187.)

A. Eichleri (Eichler's). *fl.*, spathe dirty white, 1½in. high and across, the limb dull reddish-brown, waved and crenate or lobulate; spadix 6in. long, erect; peduncle very short. April. *l.* trisected; divisions shortly petiolulate, 9in. long, the lateral ones bisected, the middle one trisected, the segments pinnatifid; leaflets two or three pairs, sessile, elliptic-ovate, the terminal one 3in. to 4in. long. Western tropical Africa, 1882. (B. M. 7091.)

A. Elliottii (Elliott's). *fl.*, spathe pink and green, with blotches and zones of brownish-purple, short, broad-hooded, with a small aperture; spadix purple, shorter than the spathe; peduncle 1ft. high. *l.* trisected-pinnatifid, 1ft. high. Tuber fleshy. Sierra Leone, 1894. (B. M. 7549.)

Amorphophallus—*continued.*

A. glabra (smooth). *fl.*, spathe olive-green outside, mottled with brown, white within, about 6in. long, rather closely rolled round the spadix in the cylindrical part; spadix shorter, sulphur-yellow, black-dotted; peduncle upwards of 1ft. in height. Queensland. 1895.

A. Lacourii. The correct name is *Pseudodracontium Lacourii.*

A. Leopoldianus (Leopold II.'s). *fl.*, spathe reddish-violet, expanded, shortly pedunculate, the lamina oval-lanceolate, long-acuminate, the margins undulated; spadix 2ft. to 2½ft. long, cylindrical. *l.* horizontally spreading, 2½ft. to 3ft. in diameter, trifariously palmately divided, the divisions bisected; segments oblong-lanceolate, loosely and irregularly bi-tripinnatisect, the ultimate segments 1½in. to 2½in. long; petioles about 1½ft. high, terete, dotted. Congo, 1837. SYN. *Hydrosme Leopoldiana* (I. H. ser. v. 23).

A. Mulleri (Muller's). *fl.*, spathe pale fuscous-yellow and spotted with white outside, yellow within, 10in. long; spadix about 12in. long; peduncle marked with white. *l.* olivaceous, white-spotted, measuring (together with the petioles) 15ft. high; segments variable in shape, undivided or bifid, often dimidiate. Java, 1875. (R. G. 1875, t. 842.)

A. oncophyllus (swollen-leaved). *fl.*, spathe tube whitish, streaked and spotted with green, 3in. long, the limb dull reddish-purple blotched with yellow, 8in. long, 5in. broad; spadix 8in. to 18in. long, the appendage creamy-yellow; peduncle 1ft. to 1½ft. long. *l.* 3½ft. broad; leaflets 6in. to 8in. long; petioles 2ft. to 3ft. long, blotched with greenish-white. Tuber 5in. to 9in. in diameter, bulbilliferous. India, 1893. Odour very disagreeable. (B. M. 7327.)

A. Teuszii (Teusz's). *fl.*, spathe green outside, dark purple-brown within, 6in. long, with a short, ovoid tube, and an open, trifid limb; spadix rather shorter than the spathe, with a greenish, cylindric appendix; peduncle very short. *l.* solitary, tripartite, with bipinnatifid-branched divisions; ultimate segments linear-lanceolate. Western tropical Africa, 1884. SYN. *Hydrosme Teuszii* (R. G. 1142).

A. variabilis (variable). A synonym of *Brachyspatha variabilis.*

A. virosus (venomous). *fl.* fetid; spathe large, green, suffused with purple and with large pale spots outside, lurid-purple within; spadix having a thick, conical, dark purple appendix; peduncle short and thick. *l.* trisected, 6ft. across; segments dichotomously pinnatifid or bipinnatifid; pinnules very unequal; petioles 4ft. high, 3½in. thick. Siam (?). (B. M. 6978.)

A. zeylanicus (Cingalese). A synonym of *Synantherias sylvatica.*

AMPELANUS. A synonym of **Enslenia** (which *see*).

AMPELIDEÆ. A natural order of mostly climbing shrubs, with jointed stems and leaf-opposed tendrils; they are chiefly found in the tropics of both hemispheres, none being indigenous in Europe. Flowers usually green, minute, regular, hermaphrodite or unisexual; petals four or five; stamens opposite the petals; inflorescence paniculately cymose, racemose, or rarely spicate, leaf-opposed. Fruit a berry, often watery, five- or six-celled. Leaves alternate, petiolate, simple or digitately three- to five-foliolate, or pedate, or rarely bipinnate. The Grape Vine (*Vitis vinifera*) is the most important plant of the order; *V. discolor, Vitis (Ampelopsis) quinquefolia* (Virginian Creeper), and *Vitis inconstans (A. tricuspidata,* Veitch's Creeper) are other well-known species in gardens. The *Ampelideæ* number about 250 species, and in the "Genera Plantarum" of Bentham and Hooker are classified in three genera.

AMPELOPSIS. Botanically, this is merely a section of the genus *Vitis.* To the information given on pp. 65-6, Vol. I., the following should be added. *See also* **Ampelovitis.**

A. Hoggi (Dr. Hogg's). This name is given in gardens to the Japanese form of *Rhus Toxicodendron.*

A. muralis (wall-loving). A self-clinging climber, of quick growth, and having brilliantly-coloured leaves.

A. sempervirens (evergreen). A garden synonym of *Vitis striata.*

A. tricuspidata. The correct name is *Vitis inconstans.*

AMPELOVITIS (from *Ampelopsis* and *Vitis*). For culture of the following, *see* **Ampelopsis.**

A. Davidi (David's). *fr.* black, borne in loose bunches. *l.* either simple, lobed, or digitate, shining green above, glabrous and glaucous beneath; petioles short, red, glabrous. North China, 1889. Hardy. (R. H. 1889, p. 204.)

Ampelovitis—*continued.*

A. intermedia (intermediate). *l.* large, coriaceous, varying from cordate and entire to palmately five-lobed; petioles, as well as the stems, beset with stout bristles. 1891. Hardy.

A. Romaneti (Romanet's). A synonym of *Vitis Romaneti.*

AMPELYGONUM. Included under **Polygonum** (which *see*).

AMPHEREPHIS. A synonym of **Centratherum** (which *see*).

AMPHIBESIS. A synonym of **Centratherum** (which *see*).

AMPHIBLEMMA (from *amphi*, both, and *blemma*, the eye; in allusion to the ambiguous character of the flowers). ORD. *Melastomaceæ.* A small genus (three species) of stove herbs or small shrubs, natives of Western tropical Africa. Flowers pink, in simple or branched cymes; calyx-limb dilated, five-toothed; petals five; stamens ten, very unequal. Leaves petiolate, membranous, ovate or ovate-oblong, acuminate, serrulated, five-nerved. Only one species calls for mention here. For culture, *see* **Melastoma.**

A. cymosum (cymose). The correct name of *Melastoma corymbosum.*

AMPHICARPÆA. SYN. *Cryptolobus* (in part). This genus embraces about seven species, natives of North America, Japan, and the Himalayas.

AMPHICOSMIA. Included under **Hemitelia** (which *see*).

AMPHIDONAX. A synonym of **Arundo** (which *see*).

AMPHIGLOTTIS. Included under **Epidendrum** (which *see*).

AMPHILOBIUM. *See* **Amphilophium.**

AMPHISCOPIA. The species formerly classed under this name are now referred to **Dianthera** and **Justicia** (which *see*). *A. Pohliana* is a synonym of *D. Pohliana.*

AMPHITHALEA (from *amphithales*, flowering round the branch). SYN. *Ingenhoussia.* ORD. *Leguminosæ.* A genus embracing nine species of small, Heath-like, greenhouse shrubs, confined to South Africa. Flowers purple or rosy, with the keel darkly tinted, axillary and sub-sessile or crowded in a leafy spike; calyx almost equally five-cleft; standard reflexed; wings oblong. Leaves alternate, simple, entire, sessile, exstipulate. *A. ericæfolia* is the only species that has been introduced, and it is doubtful if that is still in cultivation.

AMPHODUS. Included under *Kennedya. A. ovatus* (B. R. 1101) is synonymous with **K. rubicunda** (which *see*).

AMYGDALEÆ. Included under **Rosaceæ** (which *see*).

AMYGDALOPSIS. Included under *Prunus*, the correct name of *A. Lindleyi* being **P. triloba** (which *see*).

AMYGDALUS. Now included under **Prunus.** *See also* **Persica.** *A. Persica* and *Persica vulgaris* are synonyms of *Prunus Persica.*

AMYRIS ELEMIFERA. A synonym of *A. Plumieri.*

ANABASIS AMMODENDRON. A synonym of **Haloxylon Ammodendron** (which *see*).

ANACAMPSEROS. This genus includes about nine species.

A. arachnoides grandiflora (large-flowered). The correct name of *A. rufescens.*

A. rubens is a variety of *A. arachnoides.*

A. Telephiastrum is the correct name of *A. varians.* SYN. *A. rotundifolia* (L. B. C. 591).

ANACARDIUM. SYNS. *Acajuba, Cassuvium.* This genus includes about half-a-dozen species, natives of tropical America.

A. longifolium (long-leaved). A synonym of *Semecarpus Anacardium.*

ANACHARIS. A synonym of **Elodea** (which *see*).

ANACYCLUS (changed from *Ananthocyclus*, compounded of *a*, privative, *anthos*, a flower, and *kyklos*, a circle; with reference to the circle of ovaries which surrounds the disk.) ORD. *Compositæ.* A genus embracing about ten species of hardy or half-hardy, annual herbs (or with a perennial caudex), inhabiting South Europe, North Africa, and the Orient. Flower-heads radiate, mediocre, pedunculate at the tips of the branches; involucre hemispherical or broadly campanulate, the bracts in few series; receptacle convex or conical; ray florets white, yellow, or purplish, in one series, fertile or sterile, sometimes deficient; disk yellow, fertile; achenes obovate, glabrous, the outer ones two-winged. Leaves alternate, twice or thrice pinnatisect. *A. radiatus purpurascens*, the only plant of the genus in general cultivation, is a very attractive and floriferous, hardy annual, thriving under ordinary treatment.

A. radiatus purpurascens (rayed, purplish). *fl.-heads* large; ray florets white or yellow above, the under-side purplish. Summer. *l.* bipinnatifid, with small, linear segments. 1883. (R. G. 1074.) SYN. *Anthemis purpurascens.*

ANAGALLIS. This genus embraces about a dozen species, inhabiting Europe, North and South Africa, West Asia, and extra-tropical South Africa, one being scattered over nearly all warm and temperate regions; two are indigenous in Britain. To the species and varieties described on pp. 68-9, Vol. I., the following should be added:

A. collina (hill-loving). *fl.* vermilion, purplish at base; corolla large, with rounded-ovate, argutely crenulate lobes; peduncles axillary, longer than the leaves. August. *l.* spreading, amplexicaul, entire; lower ones opposite, lanceolate or ovate-lanceolate, often reflexed; upper ones lanceolate, acute. Stem shrubby at base, ascending. South-west Europe and North Africa, 1803. Nearly allied to *A. linifolia.* SYNS. *A. grandiflora* (A. B. R. 367), *A. fruticosa, A. Wilmoreana* (B. M. 3330).

A. c. alba (white). *fl.* white, yellow in the centre, abundantly produced. April to June. *l.* small, lanceolate. Stems short, erect, crowded, densely set with leaves. 1883. A charming little plant. (R. G. 1125.)

A. fruticosa is a synonym of *A. collina.*

A. grandiflora is a synonym of *A. collina.*

A. latifolia (broad-leaved). The correct name of *A. indica.* (S. B. F. G. 132.)

ANAMENIA. A synonym of **Knowltonia** (which *see*).

ANANAS. According to J. G. Baker, in his monograph of the *Bromeliaceæ*, this genus embraces only three species, natives of tropical America. Sepals ovate, acute, free to the top of the ovary; petals violet or purplish, lingulate, free, much longer than the sepals; stamens much shorter than the petals; peduncle central, its leaves spine-edged. Fruits fleshy, connate with the bracts into a large, ovoid or sub-globose syncarpium, which is often proliferous from the base (the plants can be propagated from the buds thus produced). Two of the descriptions given on p. 69, Vol. I., are here amplified.

A. bracteatus (prominently bracteate). *fl.*, petals violet; inflorescence a dense, oblong strobilus 4in. to 6in. long; bracts bright red; peduncle 1ft. to 2ft. long, its leaves bright red. April. *fr.*, syncarpium ovoid, yellow when ripe, with a large tuft. *l.* thirty to fifty in a rosette, ensiform, 4ft. to 5ft. long. Brazil (introduced from Portugal in 1820). (B. M. 5025; B. R. 1081.) SYN. *Ananassa bracteata.*

A. crocophylla (Saffron-leaved). A synonym of *Æchmea crocophylla.*

A. macrodontes. The correct name of the plant described as *A. macrodonta.* (B. H. 1878, p. 140, tt. 4, 5.)

A. Mensdorfianus (Mensdorf's). A synonym of *Æchmea Fernandæ.*

A. sativus (cultivated). Pine-apple. *fl.* about 1in. long; inflorescence an ovoid cone 3in. to 6in. long; peduncle stiffly erect, ½in. to 1in. long. April. *fr.*, syncarpium ovoid, 6in. to 12in.

Ananas—*continued.*

long (under cultivation), crowned with a tuft of twenty to thirty leaf-like, empty bracts. *l.* thirty to fifty in a dense rosette, ensiform, 3ft. to 5ft. long, 1½in. to 2in. broad. Tropical America, 1690. There are numerous varieties, including *bracamorensis, debilis, glaber, lucidus, microcephalus, Mordilona, Porteanus,* and *variegatus.* *See* **Pine-apple.**

ANANTHERIX. This is now included under **Gomphocarpus** (which *see*).

ANANTHOPUS. A synonym of **Commelina** (which *see*).

ANARSIA LINEATELLA. *See* **Peach Insect Pests.**

ANAPHALIS (said by De Candolle to be an ancient Greek name of some Gnaphalioid plant, and that it may be taken as an anagram of the very similar genus *Gnaphalium*). Everlasting. SYN. *Antennaria* (in part). ORD. *Compositæ.* This genus comprises about twenty-five species of greenhouse or hardy, erect, perennial herbs, mostly natives of tropical and temperate Asia, one (*A. margaritacea*) being broadly dispersed over North America and Eastern Asia, and also occurring in Europe. Flower-heads rather small, crowded at the tips of the branches or loosely corymbose, heterogamous or unisexual; involucre campanulate, the bracts in many series, often white; receptacle flat or convex. Leaves alternate, entire, petiolate, sessile, or decurrent. Only three species call for mention here. For culture, *see* **Antennaria.**

A. margaritacea (pearly). Pearl Cudweed; Pearly Everlasting. The correct name of *Antennaria margaritacea.*

A. Royleana (Royle's). *fl.-heads* white, ¼in. to ⅓in. in diameter, disposed in rounded corymbs; involucral bracts also white. September. *l.* sessile, ⅜in. to 1½in. long, linear or linear-oblong, obtuse or acute, woolly beneath or on both surfaces, one-nerved, flat or having recurved margins. Stems many, 4in. to 6in. high. Alpine Himalayas, 1832. Hardy.

A. triplinervis (triple-nerved). The correct name of *Antennaria triplinervis.*

ANBURY. *See* **Finger and Toes.**

ANCHOMANES. This genus embraces one or two species, natives of Western tropical Africa. Flowers monœcious, on an inappendiculate spadix; spathe marcescent, open, erect, cymbiform or lanceolate, fleshy, convolute towards the base. Leaves solitary. To the species described on p. 70, Vol. I., the following should be added:

A. dubius (doubtful). *fl.*, spathe purplish outside, cream-coloured within, elongated-oblong-lanceolate; spadix one-fourth shorter than the spathe. *l.* very large, sparsely prickly; primary segments dichotomous; secondary ones pinnatifid or pinnatisect. Rhizome tuberous, oval or oblong. Africa. (G. C. 1885, xiii., p. 669.)

ANCHUSA. SYN. *Buglossum.* This genus embraces about thirty species, natives of Europe, North and South Africa, and Western Asia, one or two of them being also found in other regions (two in Britain). The one usually grown is *A. italica,* a hardy perennial of great value in the border on account of its intense blue flowers; while to beekeepers it has an additional charm. In the wild garden, again, it is very effective, and should always find a place. To the species, &c., described on p. 71, Vol. I., the following should be added:

A. affinis (related). *fl.* blue, like Forget-me-nots, funnel-shaped above, ¼in. to ⅓in. long; racemes short, disposed in a narrow, terminal panicle. Summer. *l.* oblong, entire, slightly obtuse; radical ones 5in. long; cauline ones sessile, 1½in. long. Stem 8in. to 9in. long. Abyssinia, 1895. Perennial.

A. angustifolia (narrow-leaved). A form of *A. officinalis.*

A. hybrida (hybrid). *fl.* purple, with the processes of the throat white; raceme spike-like, at first compact, eventually elongated. June to August. *l.* oblong-lanceolate, sinuate-toothed, slightly undulated. *h.* 1ft. to 1½ft. Italy, 1820. Annual.

A. ochroleuca (yellowish-white). *fl.* yellowish-white; corolla tube as long as the calyx; bracts linear-lanceolate. July and August. *l.* lanceolate, hispid-ciliated, minutely strigillose. Stems erect, minutely villous. *h.* 2ft. Caucasus, &c. Perennial. (B. M. 1603.) The varieties *cærulescens* and *leptophylla* have bluish flowers.

Anchusa—*continued.*

A. officinalis angustifolia (narrow-leaved). *fl.* in a looser spike than in the type. May. *l.* narrower-lanceolate. *h.* 2ft. South Europe, 1640. (B. M. 1897, under name of *A. angustifolia*).

A. tinctoria. The correct name is *Alkanna tinctoria.*

ANCHUSOPSIS. A synonym of **Lindelofia** (which *see*).

ANCISTROPHYLLUM (from *agkistron,* a grapple-hook, and *phyllon,* a leaf; in allusion to the habit of the plants). ORD. *Palmæ.* A small genus (three or four species) of tufted, tall-climbing, stove Palms, natives of Western Africa. Flowers hermaphrodite, mediocre; spadix pyramidal, 4ft. to 6ft. long, distichous, doubly-branched, the branches pendulous; spathes tubular, sheathing. Fruit small, ovoid-globose, one-seeded. Leaves remote, alternate, equally pinnatisect; segments somewhat aggregated or alternate, linear-lanceolate or oblong-falcate. For culture of the species introduced, *see* **Calamus.**

A. læve (smooth). *fl.* alternately distichous, much-spreading, twin; spadix terminal, ovate, 1½ft. to 2ft. high, with six to eight primary branches. *l.* 4ft. to 5ft. long; segments nine to thirteen on both sides, broadly lanceolate-elliptic, narrowed towards the base, acuminate at apex, slightly falcate, unarmed; petioles 8in. to 9in. long. Stem 30ft. to 40ft. long, as thick as a finger, unarmed. Gaboon, &c. SYN. *Calamus lævis* (T. L. S. xxiv., p. 430, pl. 38B).

A. secundiflorum (side-flowering). *fl.* twin; spadix terminal, broadly ovate, 4ft. to 6ft. high; primary branches ten to fifteen, about 3ft. long. *l.* 12ft. to 14ft. long, long-sheathing, shortly petiolate, about 1ft. to 1½ft. apart; segments forty-five to fifty-five on both sides, linear-lanceolate, ciliate-aculeate on the margins. Stem about 1½in. thick, 50ft. to 60ft. long, unarmed. Sierra Leone, &c. SYN. *Calamus secundiflorus* (T. L. S. xxiv., p. 432, pl. 33, 41, 42).

ANCISTRUM. A synonym of **Acæna** (which *see*).

ANDERSONIA. This genus includes about nineteen species, all natives of South-western Australia. Leaves with a shortly-sheathing, often membranous base, the upper ones passing into floral leaves or bracts. To the species described on p. 71, Vol. I., the following should be added:

A. cærulea (blue). *fl.* singly terminating short peduncles or branchlets, usually crowded in a spike-like panicle; sepals pink, about ¼in. long; corolla blue, shorter than the calyx. *l.* from a broad base tapering into a long point, undulated or twisted, pubescent when young; those on the main stems ¼in. long. *h.* 1ft. to 2ft. Plant erect. (R. G. 1180, f. 2.)

A. depressa (depressed). *fl.* solitary at the ends of the branchlets; sepals greenish-white, ⅛in. to ¼in. long, glabrous or hairy; corolla blue, shorter than the calyx. *l.* with a short, broad base, subulate-acuminate, spreading, often twisted, ¼in. to ½in. long. *h.* 6in. to 12in. Plant prostrate or diffuse. (R. G. 1180, f. 1.)

A. homalostoma (flat-mouthed). *fl.* small, in dense, terminal globular heads or oblong spikes, sometimes 1in. long; sepals pink; corolla blue. *l.* spreading and sometimes squarrose, acuminate, straight or twisted, rarely above ¼in. long. *h.* about 1ft., or low and diffuse. (R. G. 1180, f. 3.)

ANDERSONIA (of Roxburgh). A synonym of **Amoora** (which *see*).

ANDREUSIA. A synonym of **Myoporum** (which *see*).

ANDRICUS TERMINALIS and **A. CURVATOR.** These are two of the commonest Galls found upon the oak. The former is the well-known Oak Apple associated with the 29th of May; and the latter, the green globular swelling, about the size of a pea, found in late spring on both sides of the leaves. It is on account of this curling of the leaves that the specific name of *curvator* has been applied. *See* under **Galls** and **Oak Galls.**

ANDROLEPIS is included by J. G. Baker under **Æchmea** (which *see*), the species retaining its specific name *Skinneri.*

ANDROMACHIA. A synonym of **Liabum** (which see).

ANDROMEDA. *See also* **Agarista, Agauria,** and **Enkianthus.**

ANDROMYCIA (name not explained by its author). ORD. *Aroideæ*. A monotypic genus. The species, *A. cubensis*, is the plant described on p. 223, Vol. IV., as *Xanthosoma helleborifolium*.

ANDROSACE. Rock Jasmine. This genus embraces about forty species, confined to the Northern hemisphere. They are alpines of the first water, and in addition to their Primula-like flowers the perennials have neat evergreen (often woolly) foliage to recommend them. Their culture, however, should never be attempted in towns. Once they are established they should remain undisturbed, as they very quickly resent interference. To those described on pp. 72-3, Vol. I., the following should be added:

A. albana (Albanian). *fl.* pinkish, crowded in sub-sessile umbels; scape erect, three or four times the length of the leaves. April to July. *l.* forming small rosettes, lanceolate-spathulate, obtuse, glabrous, deeply toothed, sessile. Eastern Caucasus, 1892.

A. alismoides (Alisma-like). A synonym of *A. lactiflora*.

A. britanica (British). *fl.* white. *h.* 2in. 1890. A hardy alpine, raised by Messrs. Backhouse, of York.

A. caucasica (Caucasian). *fl.* bright pink, produced in clusters, almost stemless. Summer. *l.* narrow, toothed, forming dense rosettes. Caucasus, 1892. A pretty species.

A. cylindrica (cylindrical). *fl.* pure white, solitary; peduncles pilose, longer than the leaves. *l.* densely imbricated, lanceolate-ovate, very obtuse, ⅛in. long, pilose, persistent and reflexed when old. Stems branched. Pyrenees, 1890. Plant tufted.

A. foliosa (leafy). *fl.* many in an umbel; corolla pale flesh-coloured, ⅛in. to ¼in. in diameter; scape solitary, erect, 3in. to 5in. high. May to September. *l.* 2in. to 3in. long, elliptic or elliptic-oblong, obtuse or acute, hairy. Rootstock woody, without stolons, sending up one or more very short stems. Western Himalayas, 1882. (B. M. 6661.)

A. lactiflora (milk-flowered). *fl.* white or blue; calyx urceolate-campanulate; corolla lobes cuneate-ovate, emarginate; scape erect, many-flowered. August. *l.* rosulate, linear-lanceolate, acute; petioles winged. Stem wanting. Siberia, 1806. Biennial. SYN. *A. alismoides*.

A. lanuginosa Leichtlini (Leichtlin's). *fl.* white, with a yellow eye. 1890.

A. macrantha (large-flowered). *fl.* pure white, borne in strong spikes. *l.* produced in rosettes and horned near the tip. Armenia, 1897. A distinct species, belonging to the *coronopifolia* group.

A. Raddiana (Raddi's). *fl.* rose-coloured. *l.* toothed, produced in rosettes. Caucasus, 1897. A pretty, biennial species.

A. rotundifolia macrocalyx (round-leaved, large-calyxed). *fl.* numerous; calyx ¼in. to ⅜in. in diameter; corolla pale rose-coloured, much shorter than the calyx; scapes slender, longer than the leaves. June. *l.* radical, 1in. to 2in. in diameter, orbicular-cordate, lobulate; petioles equalling the blades. Himalayas, 1796. A softly hairy perennial, without stolons. (B. M. 6617.)

A. sarmentosa Chumbyi (Chumby's). From the species this differs chiefly in having very short flower-stalks. It is a gem for the alpine garden.

A. sempervivoides (Sempervivum-like). *fl.* bright purple, in glandular-pubescent umbels; corolla lobes obovate, with rounded tips; scape solitary, 1in. to 3in. long, stout. May and June. *l.* tiny, in a dense rosette ¼in. in diameter, obovate-spathulate, ciliated, curled up so as to resemble a cone. Stolons 1in. to 1½in. long. Western Thibet, 1893. A remarkable species.

A. Vitaliana. The correct name is *Douglasia Vitaliana*.

A. Wulfeniana. This is regarded as a variety of *A. alpina*, with leaves less pubescent than in the type.

ANDRYALA. SYN. *Forneum*. There are about a dozen species, natives of the Mediterranean region, North-west Africa, &c. Flower-heads yellow, homogamous, terminal, on long peduncles; inner involucral bracts in one or two series, the outer ones few and short. Leaves alternate, entire, sinuate-toothed, or pinnatifid.

ANECOCHILUS. A synonym of **Anœctochilus** (which *see*).

ANEILEMA. *Anilema* (of Kunth) and *Aphylax* are synonymous with this genus, which embraces nearly sixty species dispersed over the warmer regions of the globe.

ANEIMIA. *See* **Anemia.**

ANEMAGROSTIS. A synonym of **Apera** (which *see*).

ANEMIA. Including *Coptophyllum*. Owing to the fertile segments being always wholly contracted and having the appearance of flowering spikes, the plants of this genus are popularly known as "Flowering Ferns."

Although many very interesting species have at different times been introduced, comparatively few have survived the effects of the treatment first received after their importation; yet, provided heat and plenty of light are at the disposal of the cultivator, they are not difficult to manage. Anemias will be found to thrive best in a mixture of two parts good fibrous peat, one part leaf mould, and one part sharp coarse silver sand, the plants being kept on a shelf if in a spacious house, or near the glass if in a warm pit or low house. Watering overhead is very injurious to all of them. They prefer being grown in small pots to being planted out in the Fernery, and although they are not what may be thought the ideal of decorative Ferns, as they cannot be used for general purposes on account of their vegetation being too slow, still, when grouped together or used in conjunction with other Ferns of dwarf habit or of medium size, they present a very striking appearance.

Anemias are usually propagated from spores, which germinate very freely, though some species of a naturally tufted habit may be increased by division of their crowns, an operation which should be performed between the middle of March and the end of April.

To the species described on pp. 73-4, Vol. I., the following should be added:

A. cheilanthoides (Cheilanthes-like). A popular name for *A. tomentosa*.

FIG. 39. ANEMIA COLLINA.

A. collina. This is a very distinct species, by reason of the rusty-coloured hairs which clothe the firm, upright stalks, as in Fig. 39.

A. Dregeana is a South African species, illustrated at Fig. 40.

Anemia—*continued.*

FIG. 40. ANEMIA DREGEANA.

A. fraxinifolia (Ash-leaved). A variety of *A. Phyllitidis.*

A. Gardneri (Gardner's). *sti.* firm, upright, naked, 3in. to 4in. long. *fronds* coriaceous; rachis and both surfaces naked; barren portion 4in. long, 2½in. broad, formed of four pairs of imbricated pinnæ, the lowest of which are about 1in. broad, all being borne on short footstalks and conspicuously toothed; panicle about 2in. long; peduncle about the same length. South Brazil. Stove. SYN. *A. Glaziovii.*

A. Glaziovii (Glaziou's). A garden synonym of *A. Gardneri.*

A. rotundifolia (round-leaved). *sti.* slender, erect, 6in. to 9in. long, hairy when young. *fronds*, barren portion 8in. to 12in. long, 1in. to 2in. broad, often prolonged and rooting at the extremity; pinnæ eight to twelve pairs, distantly placed, 1in. long, ¾in. broad, very obtuse, the lower side obliquely truncate at base, the outer edge finely toothed; surfaces and rachises finely hairy; panicle 2in. to 3in. long; peduncle 3in. to 4in. long, slender. South Brazil. Stove.

FIG. 41. ANEMIA TOMENTOSA.

A. tomentosa. This pretty, tropical American species is illustrated in Fig. 41.

ANEMIA (of Nuttall). A synonym of **Houttuynia** (which *see*).

ANEMIOPSIS. A synonym of **Houttuynia** (which *see*).

ANEMONE. Including *Hepatica* and *Pulsatilla.* Of the seventy species comprised in this genus, the great majority inhabit the temperate, frigid, or mountainous regions of the Northern hemisphere; a few are found in South America and South Africa, and one is a native of Australia.

Florists have made great strides with Anemones, and the various strains now upon the market are not a little bewildering to those who wish to take up these charming, hardy flowers. Most improvement is noticeable in the spring flowering kinds, for which there is great demand alike by the garden-loving public and those who grow for market. Even this section is not restricted to spring, for by planting successional batches the season may be prolonged considerably. The autumn-flowering section has also been added to, several varieties of good substance being the result.

Varieties of *A. coronaria*, both single and double, are now very numerous, the most distinct being the Double Chrysanthemum-Flowered kinds. These have beautifully imbricated petals, and remind one forcibly of the Chrysanthemum-Flowered Asters. Then there are the Great French Poppy Anemones, found in a beautiful range of colours; and the very free-flowering strain, known as the

FIG. 42. ST. BRIGID ANEMONES.

St. Brigid Anemones (see Fig. 42) which are characterised by large, mostly semi-double flowers. Seed from these last should be sown in boxes in early spring, and transplanted as soon as they are large enough. By sowing at intervals these charming flowers may be had over a long season. Cutting winds in spring are very damaging to Anemones, and this should be borne in mind when planting.

A. fulgens has now several well-marked varieties—*flore-pleno*, *græca*, and *Leichtlinii*, being the most noteworthy. This species is still one of the most brilliant of early flowers and may be had in blossom in January. For this the roots would need to be planted in autumn. A second display could be obtained by planting a further batch in spring. It must be remembered that a somewhat shaded position must be assigned these plants, more particularly those required to flower in summer. *A. fulgens*, providing it has a suitable warm soil, which

Anemone—*continued.*

it should if it is to be successfully grown, should not be disturbed very often. They may also be grown as pot subjects. Of the pretty Wood Anemone (*A. nemorosa*), there is a most useful double form. These are shade-lovers, and may be grown under trees.

The additions to the Japanese or autumn-flowering section are not numerous, the most meritorious being Lady Ardilaun, an exquisite white with a double series of petals; and Whirlwind, another semi-double, with leafy bracts. One of the most remarkable in this section is a variety with beautifully crispated foliage. These Anemones, as stated in Vol. I., are readily propagated by division of the roots. This should be undertaken in November. Nearly every portion may be relied upon to produce a good plant the next season. Plenty of water is necessary during very dry weather; or, what is still better, a mulching about the roots.

Of the host of species none are more esteemed than *A. blanda* and *A. apennina*, both of which are blue. These are amongst the easiest to increase—the former by seed as well as by division, and the latter by division.

To those described on pp. 74-8, Vol. I., the following should be added:

A. baikalensis (Baikal). *fl.* snow-white inside, suffused rose-pink outside. May to July. *h.* 9in. to 15in. Allied to *A. sylvestris.*

A. blanda scythinica (Scythian). A variety having pale blue and white flowers. Northern Kurdistan, 1895.

A. caffra (Kaffir). *fl.* rosy-white, 1½in. in diameter; sepals twelve to eighteen, sparsely silky or glabrescent; peduncle one-flowered, villous below, densely woolly above the involucre. *l.* several from the woody rootstock, rigid, glabrescent, five- to seven-lobed, the lobes biserrate; petioles 3in. to 4in. long. South Africa, 1890.

A. Eunrenia (Eunrenia). This plant, introduced into European gardens from Persia in 1894, is probably a form of *A. coronaria* or *A. hortensis.*

A. Fanninii (Fannin's).* *fl.* pure white, fragrant, 3in. to 4in. in diameter; sepals twelve to thirty, linear-lanceolate, acuminate; pedicels 8in. to 10in. long or more; scape hairy, 2ft. to 5ft. high. June. *l.* sub-orbicular, 3in. to 2ft. in diameter, coriaceous, five- to seven-lobed, velvety above, villous beneath, the lobes toothed; petioles hairy, 1ft. to 2ft. long. South Africa. A giant Anemone. (B. M. 6958; G. C. n. s., xxv., p. 433.)

FIG. 43. ANEMONE PALMATA.

A. fragifera (Strawberry-bearing). A synonym of *A. baldensis.*

A. Hepatica is a European, but not an English, plant.

A. palmata. This charming rock plant, whose yellow flowers are well known, is illustrated at Fig. 43.

A. polyanthes (many-flowered). *fl.* white, 1in. to 2in. in diameter, in simple or compound umbels, often very numerous; sepals broadly obovate or oblong. May. *l.* 2in. to 4in. in diameter, orbicular-cordate, five- to seven-lobed, but rarely below the middle; lobes coarsely and irregularly crenate; petioles very stout, 4in. to 10in. long. *h.* 1ft. to 1½ft. Himalayas. (B. M. 6840.)

A. stellata fulgens (shining). A variety differing from the type in its vermilion-scarlet flowers.

A. sulphurea (sulphur-coloured). The correct name of *A. alpina sulphurea*, which is a good species.

A. thalictroides (Thalictrum-like). A synonym of *Thalictrum anemonoides.*

ANEMONE, RUE. *See* **Thalictrum anemonoides.**

ANEMOPÆGMA. About a score species, natives of Brazil, Guiana, and Colombia, have been enumerated. Flowers white, yellow, or rarely purplish, usually racemose; calyx truncate or minutely five-toothed; corolla sub-bilabiate, the five lobes rounded or emarginate; stamens four, didynamous; leaves opposite, three- to five-foliolate; leaflets entire, the terminal one often changed to a tendril or wanting. *A. racemosum* and *A. carrerense* are the only species known in gardens.

A. carrerense (Carrera). *fl.* pale citron yellow; corolla tube 6in. long; inflorescence three- to six-flowered; peduncles about 2½in. long. April to September. *l.* opposite; leaflets two, ovate, 2½in. long, glabrous. Branches terete, striated, sparsely pubescent. *h.* 5ft. to 6ft. Island of Carrera, Trinidad, 1898. Closely allied to *A. racemosa.*

A. clematideum (Clematis-like). A synonym of *Pithecoctenium clematideum.*

ANEMONOPSIS. *Xaveria* is synonymous with this genus.

ANETHUM. Now included under **Peucedanum.**

ANETIUM. Included under **Hemionitis.**

ANGELANDRA. A synonym of **Engelmannia.**

ANGELONIA. SYNS. *Physidium* and *Thylacantha.* Twenty-two species, natives of tropical America (mostly Brazilian), are included in this genus. *A. cornigera* and *A. Gardneri* are the correct names of the two species described under **Physidium.**

A. pubescens (downy). A garden name for *A. Gardneri.*

ANGELS' EYES. *See* **Veronica Chamædrys.**

ANGIANTHUS (from *aggeion*, a vase, and *anthos*, a flower; in reference to the inflorescence). ORD. *Compositæ.* A genus embracing twenty-two species of greenhouse, annual or perennial, Australian herbs. Flower-heads numerous, in a dense cluster, spike, or compound head. *A. pusillus* has been introduced, but it is of no horticultural value.

A. aureus (golden). A garden name for *Cassinia aurea.*

ANGIOPTERIS. All *Angiopteris* are exceedingly useful for adorning the warm Fernery the year round, and the cool Fernery during summer. Whether grown in pots or planted out, they should be kept in a mixture of two parts fibrous loam, two parts rough peat, one part chopped sphagnum, and one part coarse sand: in this they thrive luxuriantly, provided that at all times they receive a liberal supply of water at the roots and are allowed plenty of room to fully expand their gigantic foliage. When they are grown in pots, a similar mixture should be used, but it is a good plan to keep the pots in water to the depth of 2in. or 3in.

Although spores of *Angiopteris* are frequently and freely produced, there is no record of any seedlings of these noble Ferns having been raised in England, or, indeed, in any other European country. The propagation of these plants is usually left to their natural disposition of frequently producing at the base of their fronds young plants, which, when sufficiently developed, may be detached without trouble. The most expeditious way of increasing Angiopteris, however, is by means of the scaly appendages with which the base of each frond is surrounded. Each of these fleshy scales contains at least two dormant buds, which, under the influence of heat and constant moisture, soon develop. The scales should be detached in their entirety and not be cut up, then laid in silver sand, covered with chopped sphagnum, and kept in a close propagating-case. Though this may be done at almost any season, February and March are the times most appropriate to such a mode of propagation, which always proves all the more rapid when done early in the spring. According to the season in which this operation is performed, it is known that from three to five months usually elapse before the first indications of growth may be noticed; but after they have made a decided start, these young bulbils rapidly gain in strength, and may soon be considered as so many independent subjects.

Angiopteris—*continued.*

A. evecta. This handsome Fern—the only species recognised by botanists—is found all over the tropics of the Old World, and is very common in sub-alpine jungles on the west side of the Madras Presidency. See Fig. 44.

ANGRÆCUM. SYN. *Ærobion.* Including *Listrostachys.* The species of this genus number about forty, and are nearly all natives of tropical or South Africa and the Mascarene Islands.

FIG. 44. ANGIOPTERIS EVECTA.

FIG. 45. ANGRÆCUM SESQUIPEDALE.

With the exceptions of *A. eburneum* and *A. sesquipedale* (see Fig. 45), all the members of this great genus that are in cultivation are of dwarf habit, and are suitable for basket or shallow-pan culture suspended near the roof-glass. *A. Scottianum* should be placed in a basket, and the terete stems wound around a block stood in the centre, the block having been previously covered with living sphagnum. The potting compost required by the other members of this genus is a layer of good sphagnum, made moderately firm at the top of the basket or pan, the remaining portion having been previously filled with clean broken crocks. Angræcums delight in a liberal amount of moisture at all seasons of the year, both in the atmosphere and at the roots.

To the species described on p. 79, Vol. I., the following should be added:

A. apiculatum (apiculate). A synonym of *A. bilobum.*

A. articulatum (jointed). *fl.* creamy-white, racemose, polymorphous, the filiform spur as long, or sometimes three times as long, as the ovary; peduncles stout. *l.* cuneate-oblong, unequally bilobed, about 6in. long. Madagascar. A dwarf species, allied to *A. bilobum.* (R. ser. i., t. 55.)

A. avicularium. *fl.* snow-white; sepals and petals lanceolate, cuspidate; lip narrow at the base, oblong, cuspidate; spur filiform, 4in. to 5in. long; peduncle more than 9in. high, bearing fifteen flowers. *l.* short and broad, cuneate-oblong-elliptic, bilobed at the point, nearly 4in. long. Probably a native of tropical Africa, 1887.

A. bilobum Dormanianum (Dorman's). A small-flowered variety, having vermilion-flaked ovaries, and vermilion tips to the sepals. 1885.

A. b. Kirkii (Sir John Kirk's). *fl.* pure white, having slender, pale brown spurs 2½in. to 3in. long; racemes drooping. *l.* narrower than in the type, ending in two divergent lobes. Zanzibar, 1882. (W. O. A. iv. 162.)

A. bistortum (twice-twisted). This species is closely allied to *A. arcuatum*, but has much smaller flowers, which are peculiar in being furnished with a loop-curved spur. Western tropical Africa, 1893. SYN. *Listrostachys bistorta.*

A. calligerum (callus-bearing). *fl.* very stiff in texture; sepals ligulate, acute, with a strong, semi-oblong callus on the keel at the very base; petals cuneate-oblong, acute; lip's plate rather ligulate, pandurate, acute, with a long, filiform, acute spur, exceeding the stalked ovary six to seven lines. *l.* slightly glaucous, ligulate, bilobed. 1887.

Angræcum—*continued.*

A. crenatum (crenate). *fl.* resembling those of *A. Chailluanum* in colour and shape, but much smaller (as is also the habit of growth). June and July. West Africa. A rare and distinct species.

A. cryptodon (hidden-toothed). *fl.* white, 1½in. across, in loose racemes; petals ligulate, acute; lip lanceolate; spur reddish at base, thrice as long as the reddish-white ovaries. *l.* three or four, obovate-oblong, 3in. long. Madagascar, 1882.

A. descendens (descending). *fl.* white; lip cuneate-ovate, acuminate; column hairy, shorter than in *A. Ellisii* (to which this fine species is related); spur stronger, more than four times exceeding the pedicels; raceme drooping, many-flowered. *l.* oblong-ligulate, obscurely bilobed at apex. Said to come from Madagascar, 1882.

A. Eichlerianum (Eichler's). *fl.* large, solitary; sepals and petals light green, lanceolate; lip white, large, obcordate, with a triangular apiculus in the notch; spur erect, conical, about as long as the sepals. *l.* distant, oblique, elliptic, obtuse. Stems tall, leafy. Loango, West Africa, 1883

FIG. 46. ANGRÆCUM ELLISII.

A. Ellisii.* The pure white, sweetly-scented blossoms of this dwarf, winter-flowering species are well shown in Fig. 46.

A. fastuosum (proud). *fl.* ivory-white, scented like Tuberoses, numerous, racemose; sepals and petals ligulate-oblong; lip obovate; spur filiform, 2in. to 3in. long. *l.* cuneate-oblong, 3in. broad, blunt and unequally lobed at apex, wrinkled, the margins cartilaginous. Madagascar. (B. M. 7204; G. C. 1885, xxiii., p. 533.)

A. florulentum (dark-flowered). *fl.* one to three in a raceme; sepals lanceolate; petals broader than the sepals; lip oblong-lanceolate, apiculate; spur filiform, one-third longer than the ovary; racemes numerous. *l.* lanceolate, bilobed, 3in. long. Stem zigzag. Comoro Islands, 1885.

A. Fournieræ (Mme. Fournier's). A synonym of *A. stylosum.*

A. Fournierianum (Fournier's). *fl.* resembling those of *A. Eichlerianum*, but pure white and larger (2in. across), the point

Angræcum—*continued.*

of the lip being protracted into a long, acute tongue; raceme long, many-flowered. *l.* 2ft. long, 1½in. to 2in. broad, very fleshy. Madagascar, 1894. (G. C. 1894, xvi., p. 43, f. 7.)

A. fragrans (fragrant). *fl.* pure white, fragrant, 2in. across the sepals, solitary, axillary or supra-axillary; lip about as long as the sepals, hastately lanceolate, acute, grooved down the centre; peduncle and ovary 2½in. long. *l.* few, towards the top of the stem, 3in. to 4in. long, ½in. to ¾in. broad, deeply two-lobed at the tip. Stem 6in. to 10in. long, climbing. Bourbon and Mauritius, 1887. (B. M. 7161.)

A. funale (cord-like). A synonym of *Dendrophylax funalis.*

A. fuscatum (fuscous). *fl.* numerous, in a thin, lax raceme; sepals ochreous, the lateral ones reflexed; petals broader than the sepals; lip white, oblong, acuminate; spur brown, long, filiform, flexuous. *l.* cuneate-oblong, unequally bilobed. Madagascar, 1883. The habit of this plant is much in the way of *A. bilobum.* (R. G. 1234; R. H. 1887, p. 42.)

A. Germinyanum (Comte Adrien de Germiny's).* *fl.* pure white, solitary, on axillary peduncles; sepals and petals long, subulate; lip broad, suddenly contracted in the middle into a filiform, reflexed tail, 1in. long; spur greenish-white, 3in. long. *l.* linear-oblong, 2in. to 3in. long, sessile, unequally bilobed at apex. Stem climbing, 1ft. to 1½ft. long. Madagascar, 1888. (B. M. 7061.)

A. Grandidierianum (Grandidier's). *fl.* ivory-white, about the same size as those of *A. Chailluanum;* sepals cuneate-oblong, acute; petals spathulate, apiculate; lip cordate-pandurate or cordate-oblong, blunt, with a long, filiform spur; raceme one- to three-flowered. *l.* thick, oblong, obtuse and unequally two-lobed at apex. Comoro Islands, 1887. (R. H. 1887, p. 42.) SYN. *Aëranthus Grandidierianus.*

A. Henriquesianum (Henriques'). This is closely allied to *A. bilobum*, but is smaller in all its parts. St. Thomas' Island, 1890.

A. Hildebrandtii (Hildebrandt's). *fl.* orange-yellow; lip oblong, acute; spur filiform, clavate, shorter than the ovary. *l.* ligulate, unequally bilobed. Comoro Islands. An elegant but small-growing plant.

A. Humblotii (Leon Humblot's).* *fl.* ivory-white, comparable to those of *A. sesquipedale*, but having a much shorter spur, which is funnel-shaped at the base, then filiform and bent abruptly upwards. *l.* numerous, sword-like, stout, falcate, 8in. to 9in. long. Comoro Islands, 1885. A grand plant. SYN. *Aëranthus Leonis* (G. C. n. s., xxiv., pp. 80-81; R. 70; W. O. A. 213).

A. hyaloides (crystal-like). *fl.* of a transparent white, small, distichous and alternate, on short pedicels; sepals, petals, and lip similar, oval-oblong, acute; racemes ten- to fifteen-flowered. *l.* five to seven, oval-oblong, spreading, obtuse or two-lobed at apex. Stems about 1in. high. Madagascar, 1879. A tiny plant.

A. ichneumoneum (ichneumon-like). *fl.* loosely arranged on a long axis; sepals and petals dirty ochre-white, ligulate, with a curious spur. *l.* ligulate, dark green, 1ft. long, 2in. broad, unequal at apex. Western tropical Africa, 1887.

A. imbricatum (imbricated) *fl.* sweet-scented, in cluster-like racemes; sepals and petals creamy-white, lanceolate; lip orange and yellow, flabellate, retuse, apiculate, convulute, the spur recurved, blunt, not half as long as the blade of the lip, which it nearly touches. *l.* leathery, cuneate-oblong, bluntly bilobed. Stem tall, strong. 1887. SYN. *Saccolabium Barbeyæ.*

A. Kimballiana (Kimball's). A garden name for *Æonia polystachya.*

A. Leonis (Leon Humblot's). A. synonym of *A. Humblotii.*

A. Mooreanum (Moore's). This is described as "a pretty little species, with salmon-coloured flowers." 1897.

A. Obrienianum (O'Brien's). *fl.* greenish-white, with a long spur. *l.* thick. 1893. Allied to *A. Chailluanum.*

A. ophioplectron (snake-spurred). *fl.*, sepals and petals greenish-yellow, narrow, acuminate; lip white, triangular, acuminate, with an ochre-reddish, filiform spur four times as long as itself. Madagascar, 1888. SYN. *Aëranthus ophioplectron.*

A. pachyurum (thick-tailed). *fl.*, sepals and petals ½in. long; lip ½in. long, elliptic, apiculate; spur curved, 2½in. to 3in. long; racemes pendulous, 6in. to 9in. long, many-flowered. *l.* sub-spathulate, oblong, bilobed, 3in. to 3½in. long. Stems short. British Central Africa, 1891.

A. pallidum (pale). *fl.* white, disposed in numerous long spikes. *l.* 2ft. long. West Africa, 1890. Allied to *A. pellucidum.*

A. polystachyum (many-spiked). A synonym of *Æonia polystachya.*

A. porrigens (extended). *fl.* creamy-white. 1894. SYN. *Listrostachys porrigens.*

A. primulinum (Primrose-like). Probably a natural hybrid between *A. hyaloides* and *A. citratum*, with the characters of the latter predominating, except in the spur, which is lin. long, twice sharply bent, and pendulous. Madagascar, 1890.

Angræcum—*continued.*

A. rostellare (beaked). *fl.* resembling those of *A. fuscatum* in shape, but having a distinct, long-linear, ascending, rostellar process, and spathulate, apiculate petals; peduncles numerous, many-flowered. *l.* cuneate-oblong, bilobed at apex, unusually soft. 1885.

A. Sanderianum (Sander's).* *fl.* snow-white, 1¼in. across; sepals and petals spreading; lip triangular; spur 3in. to 4in. long; spikes 1ft. long, gracefully drooping, bearing two rows of flowers. Early spring. *l.* tongue-shaped, about 6in. long, shining green, the margins tinged with red. Madagascar, 1888.

A. Smithii (Smith's). *fl.* brownish, very small; racemes slender, short, 1in. long, eight- to ten-flowered. Stems very short, leafless. German East Africa, 1895.

A. stylosum (having a prominent style). This species is closely related to *A. bilobum*, but the flowers are about twice as large; they are white, with a brownish spur. Madagascar, 1895. SYN. *A. Fournieræ* (R. H. 1896, p. 256).

A. tridactylites (three-fingered). *fl.* buff, distichous, ¼in. in diameter; sepals and petals ovate, acute; lip three-lobed, with two fleshy, marginal teeth at the base; racemes lateral, about 2in. long. *l.* linear, 3in. to 5in. long, unequally bidentate. Sierra Leone, 1888.

A. Veitchii (Veitch's). A hybrid between *A. sesquipedale* and *A. eburneum.*

ANGUILLARIA (named in honour of Luigi Anguillara, a professor of botany at Padua, who died in 1570). ORD. *Liliaceæ*. A small genus (two species) of Australian, bulbous plants, only differing from *Wurmbea* in having the perianth segments distinct from the base. *A. dioica* (SYN. *A. biglandulosa*) has been introduced, but is probably not now in cultivation.

A. indica (Indian). A synonym of *Iphigenia indica.*

ANGUILLILIDÆ. *See* **Eelworms** and **Nematoid Worms.**

ANGUINA. *See* **Trichosanthes anguina.**

ANGULOA. The Peruvian and Colombian Andes are the home of these plants. They are best accommodated in the intermediate house during the growing season, when they require a liberal amount of moisture at the roots. After the growth has matured, less moisture will be required—sufficient only, in fact, should be given to keep the "bulbs" in a plump condition. A cool, brighter, and a more airy position should also be afforded. To ensure satisfactory flowering, a thorough ripening is a necessity. The plants are deciduous when properly ripened. To the species and varieties described on p. 79, Vol. I., the following should be added:

FIG. 47. FLOWER OF ANGULOA CLOWESII.

A. Clowesii macrantha (large-flowered). *fl.* bright yellow, spotted red, larger than in the type. July. Colombia. A fine but scarce variety. A flower of the typical species is shown in Fig. 47.

A. dubia (doubtful). *fl.* yellow, the sepals and petals covered on the inside with small, purple spots; lip white, blotched purple inside at base. Colombia. Supposed to be a hybrid between *A. uniflora* and *A. Clowesii.*

A. Hohenlohii (Hohenlohe's). A synonym of *A. Ruckeri sanguinea.*

A. intermedia (intermediate). A synonym of *A. media.*

A. Madouxiana (Madoux'). A garden hybrid, supposed to be between *A. Ruckeri* and *A. uniflora.* 1894. (L. 434.)

Anguloa—*continued.*

A. media (intermediate). *fl.*, sepals and petals orange-yellow outside, brownish-purple internally, the lateral sepals being marked with a central, orange line; side lobes of the lip reddish-brown, the disk ochre, the anterior lobe short. A garden hybrid, probably between *A. Clowesii* and *A. Ruckeri.* SYN. *A. intermedia.*

A. purpurea (purple). A synonym of *A. Ruckeri sanguinea.*

A. Ruckeri alba (white), *fl.* pure white. 1883.

A. R. media (medium). *fl.*, sepals and petals yellow, strongly dotted with carmine over the whole of the inner surface; lip carmine. Colombia. 1887. A pretty variety. (L. 53.)

A. R. retusa (retuse). *fl.* yellowish outside, spotted dark purple within; lateral lobes of the lip rectangular, the middle lobe small, reflexed, hairy. 1883. A remarkable variety.

A. Turneri (Turner's). *fl.* pink, the sepals and petals densely spotted inside with bright rose-colour. May and June. Colombia. A beautiful plant.

A. uniflora eburnea (ivory-coloured). *fl.* ivory-white, 1892. (L. 348.)

A. u. Mantini (Mantin's). *fl.* slightly tinted with rose. 1895.

A. u. Treyerani (Treyeran's). *fl.* having the base of the lip marked with more numerous rosy bars than in the type. 1892. (L. 310.)

A. u. Turneri (Turner's). *fl.* bold; sepals pink, lighter on the back; petals bright rose-pink on the inside. 1896. A tall-growing form.

A. virginalis (virgin-white). *fl.* white, spotted dark brown. June and July. Pseudo-bulbs dark green. *h.* about 1ft. Colombia.

ANGURIA. This genus embraces about forty species, natives of tropical America. *A. Warscewiczii* is worth growing. It thrives in a rich soil of loam and peat, and may be propagated either by seeds or by cuttings.

A. Warscewiczii (Warscewicz's). *fl.* of a rich scarlet, spicate; calyx of the male flowers cylindrical; petals spreading, orbicular. Winter. *l.* petiolate, cordate, trifoliolate, dark green; leaflets stalked, the lateral ones somewhat hastate, the middle one obovate-oblong, all shortly acuminate, sinnate-angled. Panama, 1862. (B. M. 5304.)

ANHALONIUM (from *an*, without, and *helos*, a nail or spike; in allusion to the spineless tubercles). ORD. *Cacteæ*. A genus embracing about a dozen species of greenhouse, succulent perennials, natives of the Andean regions, from Northern Mexico to Peru. They are closely allied to *Mammillaria*—indeed, are included under that

FIG. 48. ANHALONIUM FISSURATUM.

Anhalonium—*continued.*

genus by Engelmann and by the authors of the "Genera Plantarum"—but for garden purposes may well be kept distinct. Seeds rather large, tubercled. Tubercles almost leaf-like, triangular, smooth, or warted and fissured above. For culture of the species introduced, *see* **Mammillaria.**

A. Engelmanni (Engelmann's). A synonym of *A. fissuratum.*

A. fissuratum (fissured). *fl.* rose-coloured, 1½in. wide, growing from the middle of the stem. September and October. Stem and rootstock shaped like a top, the rootstock being thick and woody; tubercles arranged in a thick layer, spreading from the centre, rosette-like. Mexico, 1885. This species resembles some of the Gasterias. SYN. *A. Engelmanni.* See Fig. 43.

A. furfuracea (scurfy). *fl.* lin. long; sepals brownish; petals white or pinkish. Tubercles shorter and more pointed, the surface irregularly mamillate, and the apex a cup-like depression containing the little cushion of hairs. Otherwise like *A. prismaticum.*

A. prismaticum (prismatic). *fl.* white, terminal, copiously woolly at the base. Stem wanting; tubercles radical, lin. broad, spirally imbricated, cartilaginous outside, deltoid, obtuse or retuse, somewhat prism-like in section; axils woolly. Mexico, 1888. SYNS. *Mammillaria aloides, M. prismatica* (B. M. 7279).

A. Williamsii (Williams'). A synonym of *Echinocactus Williamsii.*

ANIA. A synonym of **Tainia** (which *see*).

ANIGOSANTHUS. *See* **Anigozanthos.**

ANIGOSIA. A synonym of **Anigozanthos** (which *see*).

ANIGOZANTHOS. SYN. *Anigosia.* Eight species, confined to South-western Australia, are included in this genus. To the information given on pp. 79-80, Vol. I., the following should be added:

A. coccinea is synonymous with *A. flavida.*

A. fuliginosus (blackish-brown). A synonym of *Macropidia fumosa.*

A. Manglesii angustifolia (narrow-leaved). *l.* linear, strongly acuminate. (B. R. 2012.)

A. rufa (red). The correct name of *A. tyrianthina.*

ANILEMA. *See* **Aneilema.**

ANIMAL MANURES. Under this term is included all manure from cattle, poultry, fish, &c., whether obtained directly or indirectly. Farmyard manure is usually a mixture of animal and vegetable manure, as the voiding of the animals is mixed with straw, peat-moss, litter, or whatever is employed for bedding. If this latter be kept under cover and fairly dry, it is a perfect plant-food, and also acts chemically on the soil; but if exposed to wet much of the fertilising matter is lost, and the manure becomes of little value. From five to ten tons, according to the state of the land and the crop to be grown, is a moderate application per acre. Market-gardeners occasionally manure much heavier, but they crop their land in proportion.

Bone-meal, and bones in a coarser form, are valuable fertilisers; and the same may be said of fish manure in any form. Both are applied to various crops at the rate of 3cwt. to 5cwt. per acre. The best time for applying this manure is early in the season, when growth is commencing. Blood, again, is a powerful animal manure if properly prepared. Horn-shavings, hoof-parings, hair, and tanners' waste (consisting of hair and skin-scrapings) are all more or less rich, and are invigorating to nearly all crops. Shoddy has found much favour with hop-growers and others, and is made of cut woollen rags. Ground oyster-shells also constitute valuable manures, especially for Vines and stone-fruit bearing trees. In fact, almost everything belonging to animal life may be utilised for manure if it is available for nothing else.

ANISACANTHA (from *anisos*, unequal, and *akanthos*, a spine; application not clear). ORD. *Chenopodiaceæ.* A small genus (six species) of branched, greenhouse shrubs or under-shrubs, all Australian. Flowers solitary in the axils. Leaves linear, alternate, sessile. One species—*A. divaricata*—has been introduced, but is probably no longer cultivated.

ANISANTHERA (of Griffith). A synonym of **Adenosma** (which *see*).

ANISANTHERA (of Rafinesque). A synonym of **Caccinia** (which *see*).

ANISANTHUS. Included under *Antholyza. A. splendens* is synonymous with **Antholyza caffra** (which *see*).

ANISOCALYX. A synonym of **Herpestis** (which *see*).

ANISOCAMPIUM. Included under **Nephrodium** (which *see*).

ANISOGONIUM. Included under **Asplenium** (which see).

ANISOLOBUS. A synonym of **Odontadenia** (which *see*).

ANISOMERIS. A synonym of **Chomelia** (which *see*).

ANISOPTERYX ÆSCULARIA. *See* **Plum Insects.**

ANNESLEA (of W. Hooker). A synonym of **Calliandra** (which *see*).

ANNESLEA (of Roxburgh). A synonym of *Euryale, A. spinosa* being identical with **E. ferox** (which *see*).

ANNUAL MULLEIN. *See* **Verbascum Boerhaavii.**

ANNUAL RING. The ring or cylinder of wood produced by exogens during one year.

ANNUALS. The value of these plants in the outside garden is frequently discounted owing to the way in which they are treated by the cultivator. It is commonly supposed that because of their somewhat ephemeral nature these plants do not require as much attention to bring them to perfection as do the more permanent occupants of bed and border with which they are associated. Such is a mistake, and it is the slipshod culture which Annuals frequently receive that more than anything else tends to bring them into disrepute. Most important, for instance, is the soil. This should always be fairly rich and friable, the latter condition being very essential at seed-time. A pasty soil at the time of seed-sowing is responsible for many failures. Then the actual depth at which to sow ought to be considered alike in relation to the soil and the sorts under cultivation. The seeds of Annuals, like those of all other plants, vary considerably, and a depth that would be suitable to one kind would be absolutely fatal to the chances of another. The smallest seeds, of which Mignonette is a familiar example, should only have the lightest of covering sifted over them, whereas Sweet Peas and Nasturtiums should have three or four times their bulk of soil to cover them—¼in. or more.

In all cases, the gardener should bear in mind that, although a certain amount of thinning is absolutely necessary, much of the labour involved might be saved by judicious sowing. Light and air are very important factors in the production of sturdy plants, and with those Annuals sown in autumn to provide an early spring display it is very essential, otherwise growth will be sappy and the seedlings will damp off. For autumn work the seeds should be sown in drills, as then the hoe can be more vigorously applied to keep down weeds and to maintain an open condition of the soil, while, of course, thinning is facilitated. Now as to the thinning. The first should be made as soon as the seedlings are large enough to handle; the second should take place a fortnight or so later, leaving the plants some 2in. or so apart; and the third when the plants again show signs of overcrowding. In the last weeding out the gardener will have to be guided by the habit of the plant under consideration. With large-growing kinds from 9in. to 1ft. will not be too much space. Opinions differ as to the best means of employing Annuals, and after all it is largely a question

Annuals—*continued.*

of individual taste. They may be effectively introduced into beds, either alone or in conjunction with perennials, or in the mixed border; while not a few make pretty rockwork plants. Though not often practised by the amateur, Annuals may be readily grown in pots for greenhouse, room, and window decoration; and several make charming basket subjects. There are many ways which will occur to the ingenious gardener of showing off to advantage the various members of this much-abused group. Some Annuals will be best displayed by allowing them to trail over window-boxes; others will look well when growing up wire, twisted into various shapes, or when climbing over an informal arch, or the more formal trellis; and yet others look well simply as edging plants. In very poor soils the gardener is often puzzled to know what floral subject to try. There is nothing better than the Nasturtium, which will blossom luxuriantly in a spot which would be fatal to the chances of almost any other subject. On the score, too, of cheapness Annuals generally should appeal; while the ease with which they are increased adds another point of interest. To obtain, however, a maximum of blossom from Annuals they must not be allowed to seed. The flowers should be removed directly they are past their best. They must also be kept watered should a period of drought set in. At such times, too, it will be found of very great advantage to provide plants like Sweet Peas with a mulch. This tends to preserve the soil in a moist condition, and is better than the too frequent use of the watering-pot. Stakes must be provided for plants needing such support as early as possible; there is no necessity nowadays to use anything unsightly for this, as the light-looking bamboo sticks can be employed for most; while for graceful subjects, like Gypsophilas, the support may consist of small branches of birch, which are soon hidden by the luxuriant growth of the subject under cultivation. Sweet Peas may be usefully employed for window-boxes by allowing the plants to droop over instead of providing them with stakes. Slugs are the greatest enemies to the majority of Annuals, and they must be either trapped by means of lettuce-leaves or bran-heaps, or prevented by surrounding the plants with coarse sand and soot.

Annuals—*continued.*

For providing a display of varied flower and foliage the gardener should look to the following genera: *Abronia, Acroclinium, Adonis, Ageratum, Alonsoa, Amarantus, Alyssum, Ambrosia, Asperula, Aster* (Victoria, Comet, Chrysanthemum-flowered, Bouquet, and Quilled), *Bartonia, Bidens, Brachycome, Cacalia, Calendula* (Meteor and Orange King), *Campanula, Centaurea, Chrysanthemum, Clarkia, Collinsia, Convolvulus, Coreopsis, Cosmos, Delphinium, Dianthus, Erysimum, Eucharidium, Gilia, Godetia,* Grasses in variety *(Bromus, Briza, Coix, Eragrostis, Lagurus, &c.), Gypsophila, Helianthus, Helichrysum, Impatiens, Ionopsidium* (for foot of rockwork this is excellent), *Jacobæa, Lavatera, Leptosiphon, Limnanthes, Linaria, Linum, Lupinus, Martynia, Mathiola, Nasturtium, Nemophila, Nicotiana, Nycterinia, Papaver, Perilla, Phlox, Portulaca, Reseda, Rhodanthe, Salpiglossis, Salvia, Sanvitalia, Saponaria, Scabiosa, Schizanthus, Schizopetalon, Silene, Statice, Tagetes, Torenia, Whitlavia, Xeranthemum,* and *Zinnia.*

ANODA (from *a*, privative, and *nodus*, a knot; the pedicels are without the articulation observable in the allied genus *Sida*). ORD. *Malvaceæ*. A genus embracing about eight species of greenhouse or half hardy, hispid or glabrescent herbs, with the habit of *Malva*. A few of them have been introduced, but none are of any horticultural value.

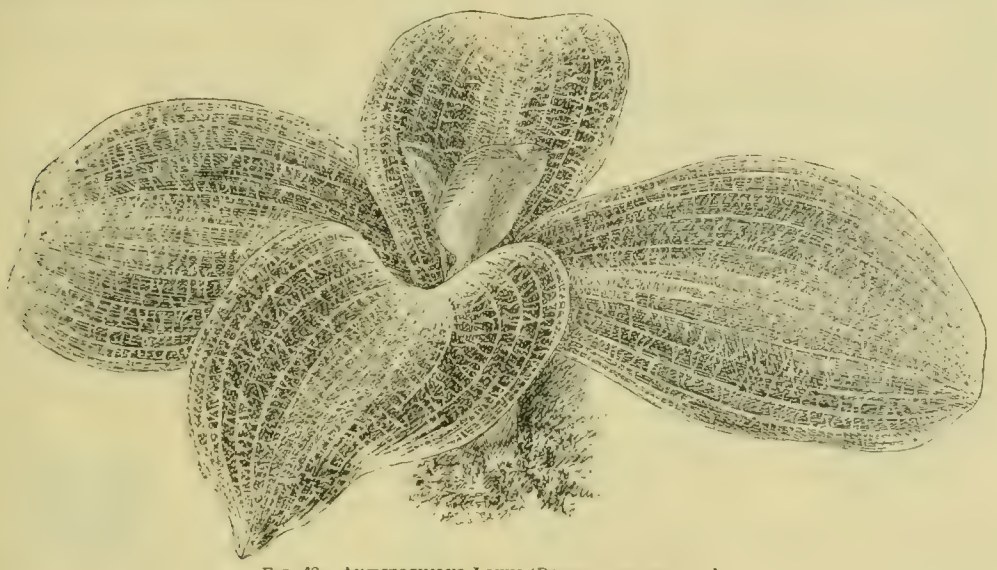


FIG. 49. ANŒCTOCHILUS LOWII (DOSSINIA MARMORATA).

ANODONTEA. Included under **Alyssum** (which *see*).

ANŒCTOCHILUS. SYNS. *Anecochilus, Chrysobaphus.* According to the authors of the "Genera Plantarum," there are only about eight really distinct species, natives of the East Indies and the Malayan Archipelago.

The numerous species and varieties of this genus are grown principally for their gaudy foliage. They are usually difficult subjects to manage; but when a suitable position is found to meet their requirements, there are few plants that are grown more easily or need less attention. Spacious bell-glasses are suitable for their culture. These should be kept close, placed on a bed of ashes or coke breeze, which should be always moist. Under these conditions, there will be a constant condensation on

Ancectochilus—*continued.*

the inside of the glass, so that very little water will be required at the roots of the plants at any time.

To the species and varieties described on pp. 81-2, Vol. I., the following should be added. Several species formerly included here are now classed under **Physurus.**

A. Boylei (Boyle's). *l.* ovate, acuminate, 2in. long and broad, olive-green, netted and pencilled over the entire surface with gold. India.

A. concinnus (neat). *l.* ovate, acuminate, rounded at base, dark olive-green, striped and netted with shining coppery-red. Assam.

A. Dominii (Dominy's).* *l.* dark olive-green, the centre marked by a pale coppery-yellow streak, and the main ribs by pale lines. A vigorous garden hybrid between *Goodyera discolor* and *Anœctochilus xanthophyllus.*

A. Eldorado (Eldorado). *l.* dark green, with small tracery of a lighter colour, deciduous. Central America. This species is difficult to cultivate; it must never be allowed to get dry at the roots, even when the leaves have died down.

A. Friderici-Augusti (Frederick Augustus'). This is identical with *A. xanthophyllus.*

A. Heriotii (Heriot's). *l.* 3½in. long, 2½in. broad, dark mahogany-colour, with golden reticulations, a shadow of network showing through the surface. India.

A. hieroglyphicus (hieroglyph-marked). *l.* ovate-elliptic, small, dark green, marked with silvery-grey blotches of hieroglyphic character. Assam.

A. javanicus (Java). A synonym of *Argyrorchis javanica.*

A. Lansbergiæ (Mme. van Lansberge's). *l.* larger than those of *Dossinia marmorata;* groundwork of upper surface dull velvety-maroon, median nerve and smaller veins emerald, lines near margin dull gold; under-surface light salmon-colour. A vigorous species. (I. H. ser. v. 1.)

A. latimaculatus (broadly-spotted). *l.* dark green, with silvery markings. Borneo.

A. lineatus (lined). A synonym of *Zeuxina regia.*

A. Lobbianum (Lobb's). A synonym of *A. Roxburghii.*

A. Lobbii (Lobb's). A synonym of *A. argyroneura.*

A. Lowii. This large and beautiful species (the correct name of which is *Dossinia marmorata*) is illustrated in Fig. 49. The under-surface of the leaves is pale yellow, tinged with rose.

A. Nevillianus (Neville's). *l.* oblong-ovate, 1½in. long, of a rich, dark, velvety, coppery or bronzy hue, marked with two rows of pale, oblong blotches. *h.* 3in. Borneo.

A. Petola (Petola). A synonym of *Macodes Petola.*

A. querceticola (Oakwood-dwelling). A synonym of *Physurus querceticolus.*

A. regalis (royal). The correct name of *A. setaceus.*

A. Reinwardtii (Reinwardt's). *l.* deep velvety-bronze, intersected with bright golden lines. Java, 1861. A handsome species, somewhat resembling *A. regalis.* (B. H. 1861, 18.)

A. Sanderianus (Sander's). A synonym of *Macodes Sanderiana.*

A. Veitchii (Veitch's). This is identical with *Macodes Petola.*

ANOGRAMME. Included under **Gymnogramme** (which *see*).

ANOIGANTHUS (from *anoigo*, to expand, and *anthos*, a flower; in allusion to the shape of the perianth). ORD. *Amaryllideæ.* A monotypic genus. The species is a greenhouse, bulbous plant, requiring similar culture to **Hæmanthus** (which *see*). It will, however, succeed outside if protected in the winter.

A. breviflorus (short-flowered). *fl.* two to ten in an umbel; perianth bright yellow, about 1in. long, regular, erect, the tube about a quarter or a third as long as the oblong-lanceolate segments; peduncle 6in. to 12in. long. October to February. *l.* three or four, contemporary with the flowers, lorate, 1ft. or more in length. South Africa, 1888. (B. M. 7072.) SYN. *Cyrtanthus lutescens,* of gardens. The variety *minor* is a dwarf, mountain form, with narrow perianth-segments.

ANOMA. A synonym of **Moringa** (which *see*).

ANOMALA FRISCHII. *See* **Vine Animal Pests.**

ANOMALA VITIS. *See* **Vine Animal Pests.**

ANOMALOPTERIS. A synonym of **Acridocarpus** (which *see*).

ANOMATHECA. This genus of three species is included, by Bentham and Hooker, and by J. G. Baker, under **Lapeyrousia** (which *see*), the specific names

Anomatheca—*continued.*

remaining unchanged; but for garden purposes it has been kept distinct in this work. To the species described on p. 82, Vol. I., the following should be added:

A. grandiflora (large-flowered). *fl.*, perianth tube 1in. long; limb bright scarlet, 2in. in diameter, the segments oblong or oblong-lanceolate; spikes lax, five- or six-flowered; peduncle (including the inflorescence) 1ft. long. October. *l.*, produced ones six to eight in a distichous, nearly basal rosette, linear, 1ft. or more in length. Eastern tropical Africa, 1883. (B. M. 6924, under its correct name, *Lapeyrousia grandiflora.*)

ANOMOCHLOA (from *anomos*, lawless, and *Chloa*, Grass; the genus differs from most other Grasses in having four stamens instead of three). ORD. *Gramineæ.* A monotypic genus. The species, *A. marantoidea* (B. M. 5331), is a stove, perennial Grass, having distinctly stalked leaves 4in. to 5in. long and 1in. to 2in. broad. It is more of a curiosity than an object of beauty from a horticultural standpoint.

ANOMORHEGMIA. A synonym of **Stauranthera** (which *see*).

ANONA. This genus embraces nearly fifty species, natives of tropical America, Africa, and Asia.

A. chrysopetala (golden-petaled). A synonym of *Guatteria Ouregou.*

A. triloba (three-lobed). A synonym of *Asimina triloba.*

ANONIS. A synonym of **Ononis** (which *see*).

ANONYMOS BRACTEATA. A synonym of **Zornia tetraphylla** (which *see*).

ANREDERA (a commemorative name; but of Anreder nothing is known). SYNS. *Beriesa, Clairisia, Siebera.* ORD. *Chenopodiaceæ.* A monotypic genus. The species is a slender, highly glabrous, greenhouse, tuberous-rooted, perennial herb, allied to *Boussingaultia.*

A. scandens (climbing). A synonym of *A. spicata.*

A. spicata (spiked). *fl.* white, small, in long, flexuous, cylindrical, axillary spikes. *l.* alternate, narrowed into the petioles, ovate, acute, entire, somewhat fleshy. Stems angular. Subtropical America, from Peru to Texas, 1889. SYN. *A. scandens.*

ANSELLIA. This genus consists of only three or four species, broadly dispersed through tropical Africa, one extending as far as Natal. *A. gigantea* and *A. nilotica,* described in Vol. I. as varieties of *A. africana,* are good species. To the species and varieties described on p. 83, Vol. I., the following should be added:

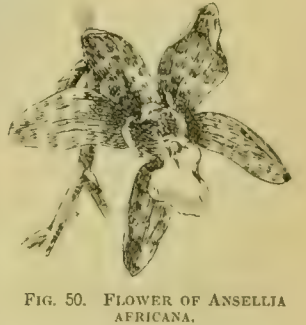

FIG. 50. FLOWER OF ANSELLIA AFRICANA.

A. confusa (confused). This differs from *A. africana* (a flower of which is illustrated at Fig. 50) in having the petals scarcely broader than the sepals. Western tropical Africa.

A. congoensis (Congo). *fl.* produced in racemes, with erect, not spreading, pedicels; sepals and petals light greenish-yellow, with dark purplish-brown spots; side lobes of the lip whitish, veined purple, the narrow front lobe yellow, the two keels on the disk almost vanishing before reaching the middle of the front lobe. Congo, 1886. A handsome plant, similar to *A. africana,* but more floriferous.

A. humilis (dwarf). *fl.* lemon-yellow, blotched and barred with chocolate, about 2in. in diameter, disposed in large panicles. Zambesi, 1891. A compact, free-growing species. The variety *pallida* differs from the type in having the ground-colour of the flowers milk-white.

ANT. *See* **Ants.**

ANTENNARIA. This genus embraces about ten species, inhabiting the mountainous regions of Europe, Asia, and North America, one being found in Australia. To the information given on p. 83, Vol. I., the following should be added. *See also* **Anaphalis.**

Antennaria—*continued.*

A. alpina (alpine). *fl.-heads* pink, sub-sessile, in a cymose cluster, or sometimes solitary; involucre livid-brownish, ¼in. long. June. *l.* radical ones spathulate, ½in. long; cauline ones linear. Flowering stems 1in. to 4in. high, bearing two to five heads, or, in the variety *monocephala*, one head. Europe, North America, &c., 1775. Plant tufted, suitable for the rockery.

A. candida (white). A garden synonym of *A. tomentosa.*

A. margaritacea and **A. triplinervis** are now classed under *Anaphalis.*

ANTHEMIS. Including *Chamomilla* (in part). Over eighty species have been described (but this number may be reduced), natives of Europe, Asia, and North Africa. Though the members of this genus known to the old-time gardener had little to recommend them, the newer kinds are excellent border plants, and furnish a quantity of useful material for cutting. They require neither special soil nor special culture, and are readily increased. The best kinds to grow are the garden forms of *A. tinctoria*, *Kelwayi*, *Kelwayi alba*, Canary Bird, and Mrs. H. T. Brooks. These are various shades of yellow and white. All are worthy of being included amongst showy, hardy, border flowers, as they last a long time in good condition, and their period of flowering extends over several months.

To the species described on p. 83, Vol. I., the following should be added. *See also* **Achillea** and **Anacyclus.**

A. Aizoon. The correct name is *Achillea ageratifolia.*

A. chia (Chio). *fl.-heads* white, with a yellow disk, solitary, on long peduncles; involucral scales oblong, with fuscous margins, April to June. *l.* petiolate, glabrous, pinnatipartite; lobes incised or pinnatifid; lobules mucronate; petioles somewhat sheathing at base. *h.* 8in. to 12in. Chio, &c. (S. F. G. 884.)

A. frutescens (shrubby). *See* **Chrysanthemum frutescens** and **Pyrethrum frutescens.**

A. macedonica (Macedonian). *fl.-heads* white, Daisy-like, with a dark yellow centre, produced in succession throughout the summer. *l.* much divided, of a very pleasing glaucous hue. *h.* 6in. to 8in. Macedonia, 1894. A neat, compact bush, about 1½ft. across. (Gn. xlvi., 1894, p. 519.)

A. montana (mountain).* *fl.-heads* white or purplish; outer involucral scales fuscous-margined August and September. *l.* petiolate, sometimes simply pinnatipartite, sometimes nearly bipartite, the lobes acute or obtuse. Stem shrubby at base, ascending, naked for a long way at the top, one-headed, and, as well as the leaves, pubescent or almost silky. Europe, &c., 1759. SYN. *A. saxatilis.*

A. purpurascens (purplish). A synonym of *Anacyclus radiatus purpurascens.*

A. saxatilis (rock-loving). A synonym of *A. montana.*

ANTHEPHORA (from *anthos*, a flower, and *phoreo*, to bear). ORD. *Gramineæ.* A small genus (about five species) of half-hardy, branched or tufted, sometimes tall Grasses, natives of tropical America and tropical and South Africa. Spikelets one-flowered; glumes three or four; spike terminal, elongated; rachis flexuous. Two of the species have been introduced, but it is doubtful if they are still in cultivation.

ANTHERICUM. Including *Liliago.* About fifty species are comprised in this genus; they are natives of Europe, tropical and extra-tropical Africa, and America. To those described on pp. 83-4, Vol. I., the following should be added. For other species formerly included hereunder, *see* **Bottionea, Bulbine, Chlorogalum, Chlorophytum, Paradisia,** and **Trichopetalum.**

A. echeandioides (Echeandia-like). *fl.* arranged in pairs in a simple, loose raceme less than 1ft. long; perianth ¾in. long, the segments orange-yellow, with a keel of three greenish ribs; peduncle simple, terete, above 1ft. long. November. *l.*, produced ones five or six, confined to the base of the stem, lanceolate, about 1ft. long, bright green, membranous, channelled. Probably Mexico, 1883. Greenhouse. (B. M. 6809.)

A. Liliastrum. The correct name is *Paradisia Liliastrum.*

ANTHIDIUM MANICATUM. *See* **Wood-boring Bees.**

ANTHOCLEISTA (from *anthos*, a flower, and *cleistos*, shut up; alluding to the shape of the blossoms). ORD. *Loganiaceæ.* A small genus (three or four species) of stove trees or shrubs, sometimes climbing, natives of tropical Africa. Flowers white or dirty yellowish, rather

Anthocleista—*continued.*

large, in terminal, trichotomous cymes, with thick branches; calyx four-parted, the segments thick, orbicular; corolla tubular-campanulate, the lobes ten to sixteen, twisted; stamens ten to sixteen, affixed below the throat; pedicels short; bracts scale-like. Leaves large, sometimes several feet long, opposite, obovate or oblong, entire; petioles dilated or sheathing at base. The following species have been introduced; they thrive in a compost of peat and loam, and may be propagated by cuttings.

A. insignis (remarkable). *fl.* yellow, about 1½in. long; cymes many-flowered. *l.* oblong, shining green, 4½ft. long, 1½ft. broad. *h.* 70ft. Swaziland, 1895.

A. macrophylla (large-leaved). *fl.* white; corolla twelve-lobed; stamens twelve. *l.* broadly obovate, obtuse, membranous, "as large as those of a common Cabbage." *h.* 20ft. Sierra Leone, 1820.

ANTHOCORIS NEMORUM. *See* **Shy Bug.**

ANTHOLYZA. SYN. *Cunonia* (of Miller). This genus embraces about a dozen species of stove and greenhouse plants, natives of tropical and South Africa. Those described on p. 84, Vol. I., are revised by Mr. J. G. Baker as follows. Several species formerly included here are now classed under **Watsonia.**

A. æthiopica (African).* *fl.* reddish-yellow, in moderately dense spikes 6in. to 9in. long; perianth-tube curved, 1½in. to 1¾in. long, the upper segment red, 1½in. long, the others much shorter, spreading. June. *l.*, basal ones several, 1ft. to 1½ft. long, 1in. or more broad. Stem branched, 3ft. to 4ft. high. Cape Colony, 1759. (B. M. 561.) SYNS. *A. floribunda*, *A. præalta*, *A. ringens* (A. B. R. 32).

A. æ. bicolor (two-coloured).* *fl.*, perianth-tube red at the top, pale yellow downwards. *l.* narrower and habit dwarfer than in the type. SYNS. *A. æ. minor* (B. R. 1159), *A. bicolor* (B. H. ii., p. 145).

A. æ. minor (lesser). A synonym of *A. æ. bicolor.*

A. æ. vittigera (striped).* *fl.*, perianth-tube bright yellow, with stripes of red. (B. M. 1172, under name of *A. vittigera.*)

A. bicolor (two-coloured). A variety of *A. æthiopica.*

A. brevifolia (short-leaved). A synonym of *A. caffra.*

A. quadrangularis (quadrangular).* *fl.* two to four in a loose spike; perianth variegated with bright red and yellow, the tube 2in. long, the upper segment red, ¾in. long, the others much smaller, greenish. April. Stem slender, 2ft. to 3ft. long, bearing two or three narrow-linear leaves. Corm large. Cape Colony, 1760. SYNS. *Gladiolus abbreviatus* (A. B. R. 116), *G. quadrangularis* (B. M. 567).

A. ringens (gaping). A synonym of *A. æthiopica.*

A. rupestris (rock-loving). A synonym of *A. caffra.*

A. Schweinfurthii (Schweinfurth's). *fl.*, perianth bright red shading to bright yellow at the base, 1½in. to 1¾in. long, curved, the tube suddenly dilated; spike simple, lax, many-flowered. *l.* five or six, linear, Grass-like, superposed, the lower ones 6in. long. Stem terete, about 1ft. long below the spike. Abyssinia, 1894.

A. vittigera (striped). A variety of *A. æthiopica.*

ANTHOMYIA. ORD. *Diptera.* Several very destructive insects fall under this genus. The most noteworthy are the Onion Fly (*A. ceparum*), Beet Fly (*A. betæ*), Radish Fly (*A. radicum*), Cabbage Fly (*A. brassicæ*), and Lettuce Fly (*A. lactucæ*). All are of somewhat dingy colouring, and resemble house-flies. They are some ⅛in. in length, or perhaps a trifle smaller; while the grub is of about the same length, whitish, and footless. There are several generations of the pests. Those above enumerated are described under the Common names given, except in the case of the Radish Fly, which is dealt with under **Radish.**

ANTHONOMUS POMORUM. *See* **Apple-blossom Weevil.**

ANTHOSPERMUM. This genus includes about twenty-five species of small shrubs, mostly South African, a few being found in tropical Africa and Madagascar. Flowers minute, dicœcious, rarely polygamous or hermaphrodite, axillary, sessile, bracteolate. Leaves small, opposite or whorled, narrow, Heath-like.

ANTHRACNOSE. This is a popular name for certain virulent fungoid diseases which attack various plants: French Bean, Vine, Currant, Spinach, Raspberry, Privet, Blackberry, and many others. The most destructive, however, is Vine Anthracnose, *Phoma ampelinum* (*Sphaceloma ampelina*). In this case, leaves, stems, and fruit are all involved, and the disease, once it has obtained a hold, is difficult to combat. On the Continent Grape Anthracnose is very prevalent; it is also known in this country and in America. For full description, *see* **Grape Anthracnose, Bean Anthracnose,** &c.

ANTHRISCUS (a name given by Pliny to a plant resembling Scandix). ORD. *Umbelliferæ*. A genus of about ten species of hardy, or half-hardy, annual, biennial, or rarely perennial herbs, with the habit of *Chærophyllum*, inhabiting North temperate and sub-tropical regions. Flowers white, in compound umbels; involucral bracts one, two, or wanting. Leaves pinnately or sub-ternately decompound. Only one species calls for mention. For culture, *see* **Chervil, Common or Garden.**

A. cerefolium (waxy-leaved). Common Chervil. *fl.* slightly radiant; umbels axillary or opposite the leaves, sessile. June. *l.* twice pinnately cut, with channelled footstalks. Stem a little hairy at the joints. *h.* 1½ft. Europe (frequently met with as an escape from cultivation in Britain). Annual. SYN. *Chærophyllum sativum* (Sy. En. B. 623).

ANTHURIUM. This genus embraces about 160 species, all tropical American, and there are now a large number of beautiful hybrids in cultivation. To those described on pp. 85-7, Vol. I., the following should be added:

A. acutum (acute-leaved). *fl.*, spathe reflexed, 2½in. long; spadix dark green, 2½in. to 3in. long. *l.* spreading, 6in. to 10in. long, 3½in. to 4in. broad across the tips of the hind lobes, triangular-hastate, gradually tapering to an exceedingly acuminate point; petioles 10in. to 12in. long, slender. Brazil, 1887.

A. album maximum (white, largest). This is a large, white-spathed form of *A. Scherzerianum*.

A. a. m. flavescens (yellowish). A synonym of *A. Scherzerianum lacteum*.

A. Allendorfii (Allendorf's). *fl.*, spathe deep crimson; spadix yellowish. 1889. A garden hybrid between *A. Andreanum* and *A. Lindenianum*. (R. G. 1293 e.)

A. Andreanum album (white). *fl.*, spathe pure white, as large as in the type, but less corrugated; spadix rigid. 1895.

A. A. amœnum (pleasing). *fl.*, spathe rose-carmine; spadix white, tipped with yellow. 1893.

A. A. atropurpureum (dark purple). *fl.*, spathe of a deep crimson, large. 1889. A hybrid between *A. Andreanum* and *A. Chantrieri*.

A. A. atrosanguineum (dark bloody). *fl.*, spathe dark crimson. 1893.

A. A. flore-albo (white-flowered). A white-spathed form.

A. A. grandiflorum (large-flowered). *fl.*, spathe 8½in. long; spadix 4in. long. 1886. (L. H. 1886, 599.)

A. A. Louisæ (Louisa's). *fl.*, spathe large, of a beautiful salmon-rose. 1889. A handsome variety.

A. A. roseum (rosy). A synonym of *A. cruentum*.

A. A. sanguineum (bloody). *fl.*, spathe of a rich, deep crimson, with darker shadings, medium-sized. 1892.

A. Archiduc Joseph. *fl.*, spathe of a beautiful, clear scarlet, broadly cordate, 4in. to 5in. long, 3½in. to 4in. broad; spadix flesh-colour, with whitish, exserted styles. *l.* cordate-ovate, rather abruptly acuminate at apex, deeply cordate at base; petioles terete, elongated. 1885. A hybrid between *A. Andreanum* and *A. Lindeni*.

A. brevilobum (short-lobed). *fl.*, spathe purplish, 2in. long, ½in. broad, narrow-lanceolate, acuminate; spadix dark purplish-brown, 3in. to 4in. long, ¼in. thick; peduncle brownish-purple, 1ft. to 1½ft. long, terete. *l.* 8in. to 10in. long, 4in. to 4½in. broad, parchment-like in texture, cordate-ovate, acuminate, bright, shining green above, paler beneath, the lobes short; petioles 1ft. to 1½ft. long, terete, channelled. Stem elongating, rooting, Native country unknown. 1887.

A. burfordiense (Burford). *fl.*, spathe brilliant scarlet, very large. 1889. A hybrid, very similar to *A. carneum*, *A. mortfontanense*, &c.

A. candidum (white). A synonym of *Spathiphyllum candidum*.

A. carneum (flesh-coloured). *fl.*, spathe light rose-colour, cordate-ovate, with longitudinal depressions; spadix rose-colour.

Anthurium—*continued.*

with a whitish glaze; peduncle terete, rather longer than the petioles. *l.* green, shortly cordate, cuspidate; petioles short, terete. 1884. A garden hybrid between *A. Lindenianum* and *A. Andreanum*.

A. Chamberlaini (Chamberlain's). *fl.*, spathe of a pale, dull puce-colour outside, shining crimson within, boat-shaped, erect, 3in. to 5in. long, 3in. broad; spadix dull reddish-purple, 6in. long, ¾in. thick, on a stalk about ¾in. long; peduncle 1ft. or more in length. *l.* cordate, 3ft. long, 2ft. broad; petioles 3½ft. to 4ft. long. Venezuela (?). 1886. A fine, bold-looking plant. (B. M. 7297; G. C. 1888, iii., pp. 464-5, f. 66-67; L. H. xxxv., t. 62.)

A. Chantinianum (Chantin's). *fl.*, spathe reddish-pink with paler stripes, ovate-triangular, 7in. long; spadix pale pink. *l.* oval-oblong, cordate at base, 1½ft. long. A garden hybrid between *A. Houlletianum* and *A. Andreanum*. 1889.

A. Chantrieri (Chantrier's).* *fl.*, spathe ivory-white, erect, oblong, acuminate; spadix dark violet; peduncle green, terete, shorter than the petioles. *l.* triangular or rhomboid, acuminate, with widely spreading basal lobes, dark shining green; petioles olive-green, terete. 1884. A vigorous hybrid between *A. subsignatum* and *A. ornatum*.

A. chelseiense (Chelsea). *fl.*, spathe rich crimson, smooth and glossy, broadly cordate, cuspidate at apex, 3½in. to 5in. long, 2½in. to 3½in. broad; spadix at first yellowish at the apex, the basal part white. *l.* resembling those of *A. Veitchii*, but more ovate in form, and having fewer and less arched veins. 1885. A garden hybrid between *A. Veitchii* and *A. Andreanum*.

A. crassifolium (thick-leaved). *fl.*, spathe light green, reflexed; spadix dull green, sessile, 2in. long; peduncle green, terete, as long as the petioles. *l.* ovate-lanceolate, very thick and stiff, with a very short, rigid mucro at the obtuse apex; petioles long. 1883.

A. cruentum (bloody). A garden hybrid, of the same origin as *A. mortfontanense*, and resembling that plant, but having blood-red spathes. 1886. SYN. *Andreanum roseum*.

A. crystallinum variegatum (variegated). A handsome variety, with very distinct variegation; in some instances the leaves are mostly ivory-white, while in others they are bronzy-green, marbled with yellow and white. 1893.

A. cymbiforme (boat-shaped). *fl.*, spathe white, large, very ornamental; spadix salmon-pink. *l.* cordate. Colombia (?), 1889.

A. Dechardi (Dechard's). A synonym of *Spathiphyllum cannæfolium*.

A. dentatum (toothed). *l.* large, cordate, deeply lobed, bright green, with paler nerves, the old ones sometimes shaded with dark glaucous reflections, the lobes ovate, acute; young leaves cordate, entire. 1884. A garden hybrid between *A. fissum* and *A. leuconeurum*. (R. H. 1884, p. 293.)

A. Desmetianum (De Smet's). *fl.* spathe carmine-scarlet, large, cordate-ovate acute, goffered; spadix ivory-white, tipped with golden-yellow, short. *l.* hastate. A hybrid between *A. Andreanum* and *A. Leopoldi*. (L. H. xxxv., t. 52.)

A. Devansayanum (Devansay's).* *fl.*, spathe and spadix erect, the latter stipitate. *l.* cordate, wavy, acuminate, erect; petioles terete. 1883. Garden hybrid. (R. H. 1882, p. 289.)

A. Dr. Lawrence. *fl.*, spathe salmon-pink, 8in. by 7½in. *l.* deep green. 1898.

A. eburneum (ivory-white). A garden hybrid between *A. Andreanum* and *A. ornatum*. 1891.

A. Eduardi (Eduard's). *l.* somewhat triangular-ovate, having a very open sinus and rounded basal lobes, dark green, with a violaceous lustre; petioles short, firm, terete. 1884. A garden hybrid between *A. crystallinum* and *A. subsignatum*.

A. elegans (elegant). *fl.*, spathe green, broadly lanceolate, 3½in. to 3¾in. long; spadix dark purple or green. *l.* cordate-ovate in outline, pedately radiate, with nine to thirteen very unequal segments, the intermediate one nearly twice the size of the lateral ones; petioles more than twice the length of the blade. Colombia, 1883. (R. G. 1112.)

A. flavidum (yellowish). *fl.*, spathe pale yellowish or yellowish-green, spreading, oblong, abruptly cuspidate; spadix pale violet-pink, 1½in. to 3in. long, sessile; peduncle 5in. to 6in. long. *l.* cordate-ovate acuminate, 10in. to 14in. long. Colombia, 1885.

A. floribundum (abundant-flowered). A synonym of *Spathiphyllum floribundum*.

A. Frœbelii (Frœbel's). *fl.*, spathe bright, deep carmine, large, with depressions as in *A. Andreanum*. *l.* large, cordate. 1886. A fine, free-flowering hybrid between *A. Andreanum* and *A. ornatum*.

A. Galeottianum (Galeotti's). *fl.*, spathe linear-lanceolate, acuminate, slightly exceeding the elongated-cylindrical spadix, *l.* coriaceous, green above, glaucous beneath, long-linear-lanceolate, rounded and often cordate at base, long-acuminate at apex. Caudex densely leafy. Brazil, 1858.

A. gandavense (Ghent). A garden hybrid between *A. Andreanum* and *A. Chantrieri*. 1893.

A. Glaziovii (Glaziou's). *fl.*, spathe dirty green outside, dull vinous-purple within, horizontally spreading, 7in. long, 1in.

Anthurium—*continued.*

broad; spadix vinous-purple, spotted with the black stigmas, erect, shortly stipitate, 8in. long. June. *l.* four or five, sub-erect, dark, shining green, narrowly oblong-obovate or oblong-oblanceolate, obtuse or sub-acute, coriaceous, flat, strongly nerved. Rio de Janeiro (?), 1880. (B. M. 6833.)

A. Goldringi (Goldring's). A garden hybrid between *A. Andreanum* and *A. Scherzerianum*. 1893.

A. Greyanum (Grey's). A garden hybrid between *A. ornatum* and *A. Andreanum*. 1892.

A. Grusoni (Gruson's). *fl.*, spathe deep crimson, very large; spadix yellowish-pink. 1889. A garden hybrid between *A. Andreanum* and *A. Lindenianum*. (R. G. 1293 a.)

A. Gustavi (Gustav's).* *fl.*, spathe green, erect, narrow-lanceolate, shorter than the spadix; spadix cylindrical, sessile, obtuse, about 5in. long; peduncle much shorter than the petioles. *l.* roundish-cordate or cordate-ovate, sub-obtuse, 2½ft. long, 1½ft. to 2ft. broad, deeply nerved; petioles sub-terete, 2ft. long. Caudex very short, erect. Buonaventura, 1883. (B. M. 7437; R. G. 1076.)

A. Hardyanum (Hardy's). A garden hybrid between *A. Andreanum* and *A. Eduardi*. 1889.

A. Hollandi (Holland's). A garden hybrid between *A. grande* and *A. ferrierense*, 1893.

A. Hookeri (Hooker's). A synonym of *Pothos acaulis*.

A. Houlletianum (Houllet's). *fl.*, spathe pale rose-coloured, cordate-ovate, acute; spadix olive-green, passing into yellow; peduncle much longer than the leaves, terete. *l.* cordate-oblong, dark, shining green, with satiny or metallic reflections; petioles short, cylindric. 1884. A garden hybrid between *A. magnificum* and *A. Andreanum*.

A. hybridum (hybrid). *l.* broad, bluntly hastate, green, borne on brown, terete petioles. 1874. A distinct plant.

A. inconspicuum (inconspicuous). *fl.*, spathe bright green, ¾in. to 1in. long, ¼in. broad, reflexed; spadix dark violet-brown, ¼in. to 1in. long; scape 6in. to 9in. long. *l.* 9in. to 12in. long, 1½in. to 3in. broad, narrowly elongate-elliptic, narrowed to both ends; petioles 6in. to 9in. long. Stem (probably) elongating. Brazil, 1835.

A. insigne (remarkable). The correct name of the plant described on p. 97, Vol. III., as *Philodendron Holtonianum*.

A. intermedium (intermediate). *l.* deflexed, cordate, oblong-ovate, velvety green, with a slight orange tinge, the midrib and veins whitish. 1884. A garden hybrid between *A. hybridum* and *A. crystallinum*.

A. isarense. *fl.*, spathe pure white, horizontal, oblong-lanceolate; spadix pinkish-white, thick, conical. *l.* cordate-oblong, at first having metallic reflections; petioles long. A hybrid between *A. Veitchii* and *A. ornatum*, raised by MM. Chantrier.

A. Kellermanni (Kellermann's). *fl.*, spathe small; spadix longer than the spathe. *l.* light green, large, sagittate, with a broad, open, rounded sinus, and a few large teeth on the margins; auricles broad and very obtuse. Origin unknown. 1893.

A. Kolbii (Kolb's). *fl.*, spathe very deep crimson, 3in. long; spadix pale yellow. 1889. A garden hybrid between *A. Andreanum* and *A. Lindenianum*. (R. G. 1293 b.)

A. Lawrenceæ (Lady Lawrence's). *fl.*, spathe almost pure white, glistening, very large, rounded; spadix also white. 1892. A garden hybrid.

A. Lawrenceanum (Sir Trevor Lawrence's).* *fl.*, spathe dark carmine-red, bright rose at back, cordate, 6in. long, horizontal, acutely pointed; spadix carmine-red, erect, robust, 4in. long. *l.* cordate-oblong, acute, dark green, paler at back. 1888. A hybrid between *A. Houlletianum* and *A. Andreanum* (R. H. 1888, p. 12.)

A. leodiense (Liége). *See* **A. mortfontanense.**

A. Lindenianum flore-carmina (carmine-flowered). *fl.*, spathe bright bronzy-carmine, large, boat-shaped; spadix more of a rosy tint. *l.* dark green, large. 1893.

A. longispathum (long-spathed). *fl.*, spathe 1½ft. long; spadix very stout, cylindric, 2ft. long; peduncle grooved, stout, 3ft. long. *l.* 2ft. long, 1½ft. broad, thick, coriaceous, deeply cordate at base, pale green, the veins very prominent beneath; petioles long. Guadeloupe, 1888. Plant stemless.

A. lucidum (clear). *fl.* violet-purple with yellow anthers; spathe lanceolate, cuspidate; spadix shortly stalked, straight, rather longer than the spathe. *l.* shining above, pale beneath, ovate-oblong, 6in. to 8in. long, apiculate, cordate at base; petioles terete. Caudex thick. *h.* 4ft. to 5ft. Rio de Janeiro.

A. magnificum (magnificent). *fl.*, spathe green, short, oblong, recurved; spadix green, cylindrical; scape terete, rather shorter than the petioles. *l.* deeply cordate-ovate, abruptly acuminate, with large, rounded basal lobes; petioles tetragonal; stipules ovate-oblong. Cundinamarca. (R. G. 508.)

A. Mooreanum (Moore's). *fl.*, spathe purplish-green, 4in. to 4½in. long, linear-oblong, acuminate; spadix olive-brown, 5in. to 6in. long, slightly tapering; peduncle as long as the petioles. *l.* sub-hastate, 1ft. long, on petioles 1½ft. long. 1886. A hybrid between *A. crystallinum* and *A. subsignatum*, of no remarkable beauty.

A. mortfontanense (Mortefontaine).* *fl.*, spathe crimson, large, cordate; spadix whitish. *l.* elongated, cordate-oyate. 1885. An ornamental hybrid between *A. Andreanum* and *A. Veitchii*. (R. H. 1886, pp. 50, 156.) *A. leodiense* is very similar to this.

A. Ortgiesii (Ortgies'). *fl.*, spathe rather small, deep red; spadix yellowish. 1889. A garden hybrid between *A. Andreanum* and *A. Lindenianum*. (R. G. 1293 d.)

A. Paradisæ (Paradise Nursery). A garden hybrid between *A. Andreanum* and *A. ornatum*. 1891.

A. Patini (Patin's). A synonym of *Spathiphyllum Patini*.

A. pumilum (dwarf). *fl.*, spathe rounded, resembling in colour that of *A. Scherzerianum Rothschildianum*, but with more scarlet. 1896. A garden seedling or hybrid.

A. punctatum (dotted). *fl.*, spathe reddish above, green beneath, changing to greyish-green or purplish-green, spreading or reflexed, 3½in. to 4½in. long, linear-oblong, cuspidate-acuminate, the margins revolute; spadix olive-green, 6in. to 9in. long, slightly tapering; peduncle 1ft. to 1½ft. long. *l.* 14in. to 20in. long, 2¾in. to 4½in. broad, elongate-oblong, rather abruptly acute, cuneate at base, dark green above, paler and blackish-dotted beneath; petioles 6in. to 8in. long, acutely channelled down the face. Ecuador, 1836.

A. purpureum (purple). *fl.*, spathe purple on both sides, suffused green at the base, 4½in. long, 1in. broad, spreading or reflexed, more or less curled; spadix dark violet-purple, 6in. or more long, ¼in. thick. *l.* coriaceous, green, 1½ft. long, 5¾in. broad, oblong-lanceolate, acute at apex, cuneate-acute at base; petioles 3in. to 6in. long, shallowly channelled. Stem ascending. Brazil, 1837.

A. Ridolfianum album (Ridolf's white). *fl.*, spathe white, large; spadix pink. 1891. A garden hybrid; parentage not stated.

A. Roezlii (Roezl's). *fl.*, spathe snow-white, elliptic, 4in. long, long-cuspidate at apex; spadix white, distinctly stalked, scarcely longer than the spathe. *l.* cordate- or roundish-ovate, rugosely undulated, 16in. long; petioles slender, terete, 1½ft. to 2½ft. long. Colombian Andes.

A. rotundispathum (round-spathed). *fl.*, spathe roundish; spadix deep yellow. *l.* of a bright green. 1891. A hybrid between *A. Andreanum* and *A. Lindenianum*. (I. H. xxxviii., t. 119.)

A. rubrinervium (red-nerved). *fl.* very sweet-scented; spathe glaucous-green, 4in. to 6in. long, narrow-lanceolate, much spreading or recurved; peduncle reddish, 1½ft. to 2ft. long. *l.* cordate-sagittate, 12in. to 14in. long, narrowed to a long-triangular apex; young ones having reddish nerves; petioles rather longer than the leaves. Venezuela, 1820. SYNS. *Pothos rubrinervia*, *P. sagittata* (B. M. 1384).

A. salmoneum (salmon). A garden hybrid between *A. Lindenianum* and *A. Andreanum*. (I. H. 1895, t. 42.)

A. Sanderianum (Sander's). *fl.*, spathe large, shield-shaped, foliaceous. 1895. A seedling related to *A. Andreanum*.

A. Scherzerianum (Flamingo Flower) **albo-lineatum** (lined with white). A garden variety. 1888.

A. S. andegavense (Angers). *fl.*, spathe scarlet on the back, dotted with white, white within, splashed with scarlet; spadix yellow. 1883. A handsome form, resembling *Rothschildianum*. (F. d. S. 2454-5.)

A. S. atropurpureum (dark purple). *fl.*, spathe dark crimson-scarlet, roundish, large. 1894. A beautiful Aroid.

A. S. atrosanguineum (dark bloody). *fl.*, spathe rich crimson. 1888.

A. S. bispathaceum (two-spathed). A curious garden variety, having two red spathes placed opposite each other. 1890. (I. H. xxxvii., t. 107.)

A. S. bruxellense (Brussels). *fl.*, spathe and scape rich scarlet; spadix orange. *l.* lanceolate, tapering to the apex. 1887. (I. H. ser. v. 18.)

A. S. compactum (compact). *fl.*, spathe white, thickly blotched with coral-red, almost circular. 1895. (G. M. 1895, p. 244.)

A. S. Duvivierianum (Duvivier's). *fl.*, spathe white.

A. S. giganteum (gigantic). *fl.*, spathe 5in. to 6in. long, and in some cases 4in. across. Costa Rica. A brilliant variety.

A. S. lacteum (milk-white). *fl.*, spathe milk-white; spadix orange. 1886. (I. H. 1886, 607, under name of *A. album maximum flavescens*.)

A. S. maximum album (largest white). A seedling variety, with large, white spathes. 1890. (I. H. xxxvii., t. 100.)

A. S. mutabilis (changeable). *fl.*, spathe at first white, gradually becoming scarlet. 1882.

A. S. nebulosum (cloud-like). *fl.*, spathe white, dusted with red, double. 1888.

A. S. parisiense (Parisian). *fl.*, spathe of a beautiful salmon-pink; spadix brilliant orange. *l.* deep green, lanceolate,

Anthurium—*continued.*

gradually tapering to the acute apex. 1887. A robust, compact plant. (I. H. ser. v. 16.)

A. S. roseum (rosy). *fl.*, spathe of a salmon-rose colour. 1893.

A. S. Rothschildianum. The name *elegans* has been applied to what is apparently a strong-growing form; *maximum* is another sub-variety. 1896.

A. S. rotundiflorum sanguineum (round-flowered, blood-coloured). *fl.*, spathe deep blood-red. 1894.

A. S. sanguineum (blood-coloured). *fl.*, spathe dark-crimson. 1893.

A. S. Senateur Montefiore Levis. *fl.*, spathe French white, long and round, profusely dotted with intense scarlet, the dots in clusters around the margins and down the centre. 1898.

A. S. Vervaeneum (Vervaene's). A handsome, white-spathed variety. 1884. (R. H. 1884, p. 204.)

A. S. Wardii (Ward's). *fl.*, spathe of the most brilliant scarlet, 6in. long, 4in. broad. A magnificent variety.

A. S. Waroqueanum (Waroque's). *fl.*, spathe white, dotted with red; spadix yellow. 1888. This does not appear to differ from the variety *Rothschildianum.* (I. H. xxxv., t. 51.)

A. S. Woodbridgei (Woodbridge's). *fl.*, spathe of the most intense crimson-scarlet, broad, nearly 6in. long. *l.* dark green, spreading. 1882. One of the finest forms.

A. subulatum (awl-like). *fl.*, spathe white, spreading, oblong, ending in a long, subulate point; spadix purplish-red, stout; peduncle 9in. to 12in. long. *l.* dark green, elongated, cordate-ovate, cuspidate-acuminate at apex. Caudex short. Colombia, 1886. A distinct and rather ornamental species.

A. trifidum (thrice-cleft). *fl.*, spadix shortly stipitate, slender, terete; spathe reddish, reflexed, oblong-lanceolate; peduncle erect, red or reddish-brown, shorter than the petioles. *l.* 10in. to 15in. long, broadly and deeply trifid; lateral lobes obliquely oblong-ovate, obtuse, somewhat falciform, shorter than the median lobe; petioles elongated. Origin uncertain. 1876. (B. M. 6339.)

A. Veitchii acuminatum (acuminate-leaved). A variety having ovate-lanceolate, acuminate leaves. Colombia, 1885.

A. Wambekeanum (Wambeke's). A garden hybrid between *A. Lindeni* and *A. Andreanum.* 1895.

A. Wittmackii (Wittmack's).* *fl.*, spathe of a lovely deep rose-colour, 2½in. long; spadix purplish, almost cylindrical. 1889. A garden hybrid between *A. Andreanum* and *A. Lindenianum.* (R. G. 1293 c.)

Other hybrids, &c.; are: *Adriani, Crombezianum, Hanburyanum, Laingi, londinense, Palmeri, Ricasolianum, rosæflorum, roseum, Torrigianum, Valvassorii.*

ANTHYLLIS. About a score species are included in this genus; they are found in Europe, Western Asia, and North Africa, *A. Vulneraria* being the British representative.

A. cretica (Cretan). A synonym of *Eb nus cretica.*

A. Erinacea (Erinacea). The correct name is *Erinacea pungens.*

ANTIDESMEÆ. Included under **Euphorbiaceæ** (which *see*).

ANTIGONON. The three or four species, natives of Mexico and Central America, are very difficult to distinguish as such. To those described on p. 88, Vol. I., the following variety should be added:

A. leptopus albiflora (white-flowered). This variety differs from the type in having white flowers. 1888.

ANTIRRHINEÆ. A tribe of **Scrophularineæ** (which *see*).

ANTIRRHINUM. Including *Asarina.* About twenty-five species of annual or (mostly) perennial herbs, rarely sub-shrubby, sometimes twining, are included in this genus; they are broadly dispersed over the Northern hemisphere, *A. majus* and *A. Orontium* (Lesser Snapdragon) being British plants; the former, however, is not a true native, but an escape from cultivation. To those described on pp. 88-9, Vol. I., the following should be added:

A. glutinosum (glutinous).* *fl.* very pale yellowish-white, rather large, axillary, erect, the lip slightly striped with red. July. *l.* alternate, shortly petiolate, elliptic-oblong or elliptic-ovate, obtuse at both ends. Branches very fragile. Spain, 1892. A prostrate, glandular-pilose, half-hardy perennial. (B. M. 7285.)

A. Nuttallianum (Nuttall's). *fl.* purple, axillary, pedicellate, the tube of the corolla not longer than the spreading lips. *l.* ovate or sub-cordate, nearly all distinctly petiolate, the lower ones about 1in. long, the upper ones smaller. *h.* 1ft. to 2ft. California, 1888. Half-hardy annual. (R. G. 1888, t. 1275, f. 3.)

ANTIRRHŒA [also spelt *Antirhea*] (from *anti*, against, and *rheein*, to flow; in allusion to the use of the plant as a styptic). ORD. *Rubiaceæ.* A genus embracing about a score species of stove, highly glabrous trees and shrubs, natives of the West Indies, Mauritius, China, and tropical Australia. **Stenostomum** is included hereunder by Bentham and Hooker, and the only members of the genus that have been introduced to gardens will be found described under that heading.

ANTISPILA PFEIFFERELLA. *See* **Vine Moths.**

ANTITHESIA PRUNIANA. *See* **Plum Insects.**

ANTLER MOTH, or **GRASS MOTH** (*Charæas graminis*). This is a most unwelcome visitor to grass, as the caterpillars do immense damage when they assert themselves, as they frequently do, in large numbers. On the Continent they are regarded as amongst the worst Grass pests which have to be encountered; while now and again here they are unusually numerous. Belonging to the *Noctuidæ*, the Moths are rarely seen. The ravages, however, of the larvæ are readily traced.

The Moth itself is on the wing in early autumn. It is about 1½in. in the wing-expanse, and has brownish or reddish fore-wings, with markings which have been somewhat fancifully likened unto the branches of antlers. The hind-wings are small, greyish, and fringed with a paler colour. Pairing takes place soon after emergence, and, according to some authorities, the female deposits eggs to the number of 300. The larvæ are hatched out in the following spring, and soon make good use of their opportunities They live at the roots of their food-plants (thus being safe from insecticides), and preferably select the soft kinds of Grass. They are brownish, with some lighter stripes along the back, while there is also a light-coloured line in the spiracular region; they are much wrinkled. When the larvæ are full-fed, they pupate in the earth in an ingeniously constructed oval cocoon. The pupæ are blackish-brown and shining.

Remedies. With larvæ feeding as these do, it is practically impossible to suggest remedial measures. On the Continent firing the herbage has been found effectual. During autumn, too, the sweep-net may be utilised with advantage in the evening, and the perfect insects destroyed. Insectivorous birds, like crows and starlings, also devour large numbers, and should be encouraged. The caterpillars, although generally attacking Grass, occasionally turn their attention to Corn.

ANTONIANA. A synonym of **Faramea** (which *see*).

ANTROPHYUM. This genus includes *Scoliosorus.* When planted out in the warm fernery, Antrophyums make very distinct objects, and are especially valuable for growing in comparatively dark places. All are slow growers; but their fronds possess very lasting qualities. Propagation may be effected by means of the spores, which are produced in abundance; but this being a very slow process, Antrophyums are usually increased by division of their crowns in March or April. To the species described on p. 89, Vol. I., the following should be added:

A. Lessonii (Lesson's). A synonym of *A. Plantagineum.*

A. plantagineum (Plantain-like). *sti.* 1in. to 4in. long. *fronds* 6in. to 9in. long, 1½in. to 2in. broad, thick, coriaceous, sharply pointed, narrowed below; areolæ sometimes 3in. long, ¼in. broad. *sori* copious, deeply immersed, often uniting. India, &c. See Fig. 51. SYN. *A. Lessonii.*

ANTRORSE. Tending in an upward or forward direction.

ANTS. In Vol. I. some little space is devoted to a consideration of the life-history of these industrious insects. The labour of keeping them down will, however, be somewhat minimised if a still more extensive glance at their communities be taken. Reference has already been

Ants—*continued.*

made to the fact that there are three different individuals to be met with in colonies of these social insects—males, females, and workers. Primarily the object of the first two is the perpetuation of their kind; while that of the last is to act not only as food-foragers for the larvæ, but also as nurses to them and to the pupæ. The larvæ are absolutely helpless, and were it not for the good offices of the workers they would perish soon after emergence from the minute eggs. Here it may be as well to state that the so-called Ants' eggs of commerce are nothing more nor less than the pupæ of certain species, which make for themselves a silken cocoon. It is these which one sees very carefully carried about when a colony is disturbed.

The larvæ are whitish, footless maggots, and, as above stated, they have to be fed and moved about by the workers. In the pupal state the creatures have still to be looked after by the workers, even to the extent of being helped out of the skins in which they passed that portion of their life-cycle. In many other ways the workers render help, until the newly-emerged insects are generally familiar with the life of the colony. Unlike Social Bees and Wasps, Ants elaborate no cells for the reception of their larvæ.

Ants in the garden are readily combatted by persistently employing one or other of the remedies suggested in Vol. I., p. 89. Those, however, inhabiting our plant-houses, and with which an interchange of commerce has presented us, are not so readily dislodged. The fact is, heat is absolutely necessary for their well being at certain seasons of the year in our changeable climate; hence the reason of their affecting warm greenhouses, &c. Here they destroy the vital parts of flowers, causing them to die away prematurely.

To exterminate them trapping must be resorted to, and that at the opportune moment. The workers, or

FIG. 51. ANTROPHYUM PLANTAGINEUM.

Ants—*continued.*

rather some few of them, will be in evidence all the year, but the time to set the traps is in spring, when the young brood is hatched and food is absolutely necessary for their up-bringing. Then it is that the workers will be found in the greatest numbers industriously foraging for food for their charges. Now is the time for the traps. These should consist of old pieces of sponge, which should be dipped into a syrupy liquid and laid about their haunts. The sponges must be taken up periodically and plunged into boiling water. Care must be taken to wash out of them the dead bodies, and then they must again be set. In time all the workers will have been attracted, and will perish. The larvæ have still to be catered for, and the other members of the colony will have to venture forth in order to save the larvæ from perishing, only, however, to share the fate of their relatives. And in the end the whole colony will have succumbed if the trapping is persisted in. Large bones containing a little meat may also be placed in the haunts of the insects, which should be brushed off into boiling water.

Some of the Wood-Ants are very destructive to timber. Their method is to enter the trees through some kind of wound, and when once inside they tunnel in all directions, and in the end the trees rot and die. By way of an Ant-destroyer the Ballikinrain may be recommended.

ANUBIAS (name not explained by its author). ORD. *Aroideæ*. A small genus (three or four species) of stove, evergreen perennials, with a short stem, natives of Western tropical Africa. Flowers monœcious, on an inappendiculate, stalked spadix; spathe green, thick, convolute below, accrescent and persistent, but the blade deciduous; peduncle elongated. Leaves lanceolate, acute or sagittate-cordate at base; petioles elongated, long-sheathing. Only one species has been introduced. For culture, *see* **Alocasia** (to which this genus is closely allied).

A. heterophylla (variable-leaved). *fl.* small. *l.* about 1ft. long, 3in. broad, bright green, blotched with dull yellow, 8in. to 12in. long, 4in. to 6in. broad; petioles 12in. to 16in. long. Congo, 1889.

AOPLA. Included under **Herminium** (which *see*).

APALANTHE. A synonym of **Elodea** (which *see*).

APARGIA. A synonym of **Leontodon** (which *see*).

APATURIA. Included under **Pachystoma** (which *see*).

APEIBA. SYN. *Aubletia* (of Schreber). This genus includes five species, all tropical American.

APERA (from *aperos*, undivided; alluding to the flower-glume, which is entire). SYN. *Anemagrostis*. ORD. *Gramineæ*. A small genus (two species) of hardy, annual, rather tall Grasses, natives of Europe and Western Asia. Spikelets one-flowered, small, loosely paniculate; glumes three, the two lower ones empty; panicle terminal, very elegant, ample, diffuse or contracted, with numerous filiform branchlets. Leaves narrow, flat. For culture, *see* **Agrostis**.

A. arundinacea (Arundo-like). A synonym of *Stipa arundinacea*.

A. Spica-venti. The correct name of *Agrostis Spica-venti*.

APHÆREMA (name not explained by its author), ORD. *Samydaceæ*. A monotypic genus. The species is a small, erect, stove shrub or under-shrub, requiring similar culture to **Rivina** (which *see*).

A. spicata (spicate). *fl.* golden-yellow, small, in solitary, terminal, slender, erect racemes; stamens eight, twelve, or sixteen, perigynous. *l.* opposite, 2in. to 3in. long, shortly petiolate, ovate-cordate, obtusely acuminate, crenate-serrate, with six to eight pairs of deeply-impressed nerves. South Brazil, 1896. (B. M. 7393.)

APHANAMIXIS. *See* **Amoora.**

APHANOSTEPHUS. *See* **Leucopsidium.**

APHELANDRA. Syns. *Hemisandra*, *Synandra*. Bentham and Hooker include hereunder *Hydromestes* and *Strobilorachis*, but the latter has been kept distinct on p. 519, Vol. III., of this work. Nearly fifty species have been noted; they inhabit tropical and sub-tropical America, from the Argentine Republic as far as Mexico. To those described on pp. 90-1, Vol. I., the following should be added:

A. amœna (pleasing). A garden name for *A. Blanchetiana.*

A. atrovirens (dark green). *fl.* in a terminal, sessile, sub-cylindrical spike; corolla fulvous-yellow, nearly 1in. long; bracts green, six to seven lines long, closely appressed. *l.* 3½in. to 4½in. long, 1¾in. to 2½in. broad, elliptic or elliptic-ovate, rather obtuse, decurrent at base, crenate, very dark green and shining above, violet-purple beneath. Bahia, 1884. Plant dwarf. (I. H. 1884, 527.)

A. Blanchetiana (Blanchet's). *fl.* golden-yellow, the tube as long as the sepals but shorter than the crimson bracts which are 1½in. long; spike sessile. August. *l.* ovate, acute, many-nerved, narrowed at base to a short petiole. Stem thick, tall. Brazil, 1838. (B. M. 7179.) Syn. *A. amœna* (of gardens).

A. Chamissoniana (Chamisso's). The correct name of *A. punctata.* (B. M. 6627.)

A. chrysops (golden-eyed). A synonym of *A. squarrosa Leopoldii.*

A. dubia (doubtful). *fl.* of a deep red. 1894. A garden hybrid. (I. H. 1894, t. 15.)

A. fulgens (brilliant). *fl.* orange-coloured. Autumn. *h.* 1½ft. Mexico, 1847. (R. H. 1847, p. 21.)

A. glabrata (glabrous). *fl.* yellow; bracts ovate, acute, entire. Autumn. *l.* oblong, attenuated at both ends, slightly repand, cuneate at base, sessile, shining. Stems whitish when adult. South America, 1843.

A. Leopoldii is a variety of *A. squarrosa.* Syn. *A. chrysops.*

A. Liboniana (Libon's). *fl.* deep yellow, red at the apex, small, scarcely exserted; bracts bright orange, large, arranged in four rows; spike sessile, 5in. to 6in. long. *l.* 9in. or more in length, deep green with a central white line, suddenly acuminate, entire; petioles 2in. to 3in. long. Brazil, 1864. (B. M. 5463.)

A. Macedoiana (Macedo Costa's). *l.* elliptic-ovate, sub-obtuse, dark green above, the nerves margined with very pale whitish-green, the under-surface violet-purple. 1886. (I. H. 1886, 583.)

A. Margaritæ (Mdlle. Marguerite Closon's).* *fl.* bright orange or apricot-colour, growing in short, terminal spikes from between pectinate bracts. *l.* decussate, shortly stalked, elliptic, the upper surface marked with about half-a-dozen oblique bars of white on each side the midrib, the under-surface clear rose-colour. Central America (?), 1884. (B. H. 1883, 19; G. C. ser. iii., vol. ii., p. 585.)

A. ornata (adorned). *fl.* bright yellow; bracts tinged with purple, large, hairy. *l.* gradually narrowed to the base, dark green, with a distinct central paler band, ciliated; midrib purple on the under-surface. Bahia, 1858. (B. H. 1865, t. 3; J. B. 1864, p. 289.)

A. prismatica (prismatic). The correct name of *Strobilorachis prismatica.*

A. pumila splendens (splendid). This pretty form differs from the type in having acute, green bracts. 1883. (R. G. 1104.)

A. squarrosa (squarrose). *fl.* yellow, in terminal, solitary or ternate spikes; corolla 1½in. long; bracts orange, densely imbricated, 1in. to 1½in. long. *l.* crowded, elliptic, acuminate, cuneate at base, 10in. to 12in. long. Brazil. A showy, herbaceous species, of which there are two varieties, *citrina* (F. d. S. 809) and *Leopoldii* (the latter described as *A. Leopoldii* in Vol. I.).

A. sulphurea (sulphur-yellow). *fl.* of a dark or golden sulphur colour; corolla tube protruding ¾in. beyond the bract, the limb 1½in. across; spike 5in. to 8in. long. *l.* 6in. to 9in. long, broadly elliptic or elliptic-ovate, abruptly acuminate; petioles stout, ½in. to ¾in. long. Stem terete, erect, sparingly branched. Guayaquil, 1872. (B. M. 5951.)

A. tetragona (four-angled). The correct name of *A. cristata.* (B. R. 1277.)

A. t. grandis (large). *fl.*, spike crowded at the apex of the stem; rachis densely woolly. September. *l.* (with the 1½in. petioles) nearly 1ft. long, 4in. broad, with a long, tail-like point. Merida, Venezuela.

A. t. imperialis (imperial). *fl.* scarlet, four times as long as the brownish bracts; spikes terminal. *l.* ovate, acute. Central America, 1891. (R. G. 1354.)

APHELENCUS FRAGARIÆ. *See* **Eelworms.**

APHELEXIS. Bentham and Hooker refer this genus to **Helichrysum** (which *see*).

APHIDES are amongst the commonest and most widely distributed of all garden insects, and are popularly known as Greenfly; though why it is difficult to imagine, seeing that many species are very far from even approximating to that colour. In this country quite 200 species are found, and this fact alone is sufficient to invest the family with some little importance even despite the unenviable reputation which it bears with the gardener and the agriculturist. To it again belong several of the most destructive insects known to horticulture, and in support of this one only needs to instance the Grape Phylloxera and the American Blight, or Woolly Aphis, each of which is dealt with under its respective heading. Years ago before economic entomology began to make its influence felt, the visitations of Aphides, together with many fungoid diseases of plants, were vaguely ascribed to "blight."

From a cursory glance at Aphides one would be tempted to think that such fragile-looking creatures would be readily disposed of either by a very severe winter or by great and successive weather changes. That they are not, however, must be apparent to those who have paid but comparatively little attention to a complex subject. First as to weather influences. That a few viviparous females are more likely to be preserved to carry on the cycle during a mild than during a severe winter is true; but, on the other hand, it must be remembered that certain very destructive species have been observed in an active condition even during the prevalence of 11deg. of frost. Dry, hot weather is most favourable to the increase of the insects, as during copious showers they get dislodged from their hiding-places, and are frequently killed. Aphides constitute quite as formidable pests of greenhouse and orchard-house plants as they are of outdoor plants, though because of the restricted area under cultivation in the former case they are more readily dealt with.

All species of Aphides do not feed exposed. Some, like those found upon the Bean, are exposed to view; while others live for the most part in the curled-up leaves of their food-plant. Again, while many infest the leaves, others, like the Apple Aphis (*A. mali*), attack both flowers and leaves. Some, too—the Woolly Aphis and the Grape Louse—feed upon the roots; and two common species at least, feeding upon Currants, are responsible for blister-like galls, due to the irritation set up by their punctures. These are *Myzus ribis* and *Rhopalosiphum ribis.*

Apart, too, from the injury certain Aphides inflict upon the plants by extracting the sap therefrom by means of their sucker-mouths, they are also objectionable by reason of the fact that they exude a sweet, sticky secretion, popularly called "honeydew," which, together with the excreta, so block up the pores of the leaves that they are quite incapable of fulfilling their proper functions, and the tree or plant suffers accordingly. Of the honeydew-secreting Aphides some of the most familiar are *Pterocallis tiliæ*, the species found upon Limes; *A. pruni* upon the Plum; and *A. brassicæ* and *A. rapæ* upon turnips, cabbages, &c.

The Lime is not alone among ornamental trees which is attacked, and badly attacked, by Aphides of the honeydew-secreting kinds. The beautiful Copper Beech, which of late years has become such a favourite in gardens, is a great sufferer from *Phyllaphis fagi*, which is allied to that found upon the Lime. It is a green species, but being covered with a whitish substance its body-colour is not often noticed. The eyes are red and prominent. The Common Beech is also subject to similar attacks. The Larch, again, has its particular Aphis (*Chermes laricis*), but the damage done is not so great as is the case with some of the other species. The eggs are laid in spring, and the newly-hatched larvæ at once commence upon the young leaves.

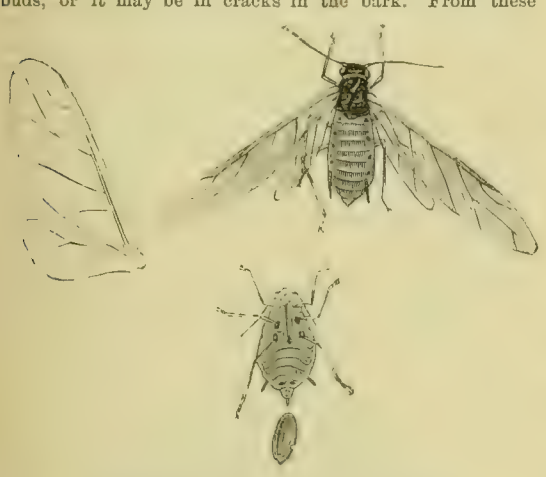
Many Aphides exhibit impartial tastes in the matter of food-plant, for when one is not available another, and

Aphides—*continued.*

that of a widely different order, suffices; and this accommodating taste no doubt stands such species in good stead. It is not, for instance, generally known that *Aphis pruni* infests not only the Plum (with which its specific name identifies it) and most other orchard and wall fruit-trees, but also Composites like Chrysanthemums and Asters; or that the Lettuce Aphis (*Siphonophora lactucæ*) will feed upon the Currant or Gooseberry; and so of many others. Equally worthy of notice is a phase in the life-history of that pest the Hop Aphis (*Phorodon humuli*), which in the autumn (September) forsakes that plant to take up its abode upon the Plum, from which in turn it migrates again to the Hop in spring. It is upon the Plum that the winter is passed in the egg-state. This is not, however, the only means by which this species is increased, for Nature has ordained that certain of the females should remain impervious to winter's cold, and in the early spring bring forth living young.

To describe in detail all the species against which the gardener is called upon to wage war would occupy too much space without a corresponding advantage accruing, especially as the methods of dealing with all are practically identical, though some species, by reason of their habits, are not so readily reached as are others. Some of the commonest and most destructive kinds are:

Apple Aphis (*A. mali*). This insect varies considerably with the different individuals found (Fig. 52). The eggs are laid in late summer in the vicinity of the buds, or it may be in cracks in the bark. From these



(By Permission of the Board of Agriculture.)

FIG. 52. APPLE APHIS (APHIS MALI). Showing Fore- and Hind-wings; Winged Viviparous Female; and Oviparous Female. (All magnified.)

hatch out in early spring the viviparous females alluded to in Vol. I., and these continue the round of life there depicted. The first symptoms of attack are a curling of the leaves, which almost invariably blacken and fall. Colour, some shade of green.

Bean Aphis (*Aphis rumicis*). This is also known as Black Fly, Dolphin Fly, and is very abundant upon Broad Beans. *See* **Bean Fly.**

Cherry Fly (*Myzus cerasi*). Although the specific name indicates the Cherry as the object of this insect's attack, the pest by no means restricts its attention to that tree, but occasionally also lays under contribution Currants as well. This is another black species. It mostly congregates on the under-surfaces of the leaves, though at times nearly every part of the tree is involved. A tree badly attacked by this insect is a sight not

Aphides—*continued.*

likely to be forgotten, for what with the excreta and the sticky secretion which has been exuded, the leaves, &c., present a most unhealthy appearance. The attack is made in spring and is long-continued, so that the drain upon the tree's resources is considerable.

Currant Aphides (*Myzus ribis* and *Rhopalosiphum ribis*). Besides the occasional Aphis visitor to the Currant noted above, there are two very troublesome pests in the Currant Aphides proper. These are greenish or yellowish in all stages, and approach one another so closely that no one but an expert would be able to separate the two species. Both kinds are to be found upon the under-surfaces of the Red and the Black Currant. These they attack, causing a reddish or reddish-yellow blister-like swelling to form; they sometimes entirely disfigure the leaves. If leaves showing blisters are lifted, they will usually be found to shelter the pests in the vicinity of the gall-like structures. Currant Aphides commence their depredations in spring, as soon as the new leaves are unfolded, and if remedial measures are not adopted, the fruit crop will be considerably endangered.

Hop and Plum Aphis (*Phorodon humuli*). This is a pale green kind, too well known to need a detailed description; while a brief sketch of its peculiar life-history has already been given. (See also **Phorodon humuli,** Vol. III.).

Pea Aphis. *See* **Pea Pests.**

Peach Aphis (*Aphis amygdali*). This reddish-yellow Aphis occasions much mischief to Peaches by blocking up the breathing-pores of the leaves with its secretions. Often, however, it is credited as well with the injury wrought by the Peach-Curl Fungus, because present at the same time.

Plum Aphis (*Aphis pruni*) is another green or yellowish-green species, very abundant upon the under-surfaces of Plum foliage. It also attacks the Peach and the Apricot. In all cases the leaves if badly-attacked "curl," and they are, moreover, covered with "honeydew," and are rendered most unsightly. The "curl" of the leaves in the case of Peaches must not be confounded with that brought about by the fungus *Exoascus deformans*, though the two not infrequently co-exist.

Rose Aphis. *See* **Rose.**

Woolly Aphis (*Schizoneura lanigera*). *See* **American Blight.**

Remedies. Before the gardener can satisfactorily deal with any insect pest, he must first of all determine how it feeds. It is useless, for instance, spraying on to trees powerful poisons if they are not likely to bring about the desired result—the diminution of the pest attacked. This, however, is frequently done, more especially with sap-sucking insects like these under notice. Now it cannot be too well known that, unlike in the case of chewing insects, poisoning the food-plant is not of the slightest use for Aphides. These creatures, by the aid of their rostra, actually bore through the poison before they begin to suck, and therefore to simply spray the tree would be labour wasted. To be really effective, the insecticide must be something which kills by contact, and there is nothing really better for the majority of Aphides than some tobacco-water or the soft-soap and quassia-chip solution recommended in Vol. I. The chief difficulty in dealing with attacks of Aphides is in the case of tall trees, for although powerful spraying-machines are now upon the market, they would hardly reach the larger ornamental trees used in the decoration of our parks and gardens, and these must be left to Nature to remedy. Most Fruit-trees and the smaller decorative subjects may, of course, be thoroughly sprayed. To ensure the greatest success spray directly the insects are noticed, and use the mixture lukewarm, as it has been found of far

Aphides—*continued.*

greater utility than when applied cold. Even warm water or soapsuds will have a cleansing effect upon the leaves, and will also be the means of killing a number of the enemy if directed with energy early in the spring. Tree-trunks may also with advantage be washed; while in the case of American Blight special treatment will be necessary, as advocated under that heading. Abol is another excellent insecticide to employ against Aphides.

The gardener is ably seconded in his efforts to keep down Aphides by many insects, but principally by several of the Ladybirds and their larvæ, which devour vast quantities. Equally useful are the Lacewing Flies, Stink Flies, or Golden Eyes. These beautiful, but fragile-looking, creatures are amongst the Aphides greatest natural enemies, and should be preserved at all costs. The eggs are fairly conspicuous, and are laid at the end of a long stalk, sometimes singly, at others in a cluster. The larvæ of some species of Lacewing Flies clothe themselves with the bodies of the Aphides, presenting a curious appearance. This is also the case with some of the *Hemerobiidæ*, which are close allies of the Lacewing Flies (which *see*). Then there are one or two species of Hover-Flies (*Syrphidae*) that render the gardener excellent service. The leech-like larvæ are very remarkable in their movements, and we have it on the excellent authority of that careful observer, Mr. Enock, that a single Hover-Fly larva has destroyed over 120 Aphides in an hour. Other insects that tend to lessen the gardener's labours are the parasitic *Hymenoptera*, of the families *Chalcididæ* and *Ichneumonidæ*. Gardeners should learn to recognise the Aphides which have been visited by the parasites of the families noted. Usually they have isolated themselves from their relatives, have assumed a dull, or even whitish hue, and aldermanic proportions. Such specimens should be left severely alone, as they almost invariably contain the egg, or perhaps the immature larva, of one of the parasites, which, as soon as it has assumed the perfect state, will make its way through the skin of the unfortunate host that for a time has given it shelter. Nor must the birds be forgotten, several of the commoner species being exceptionally fond of Aphides.

Indoors the XL All Vaporiser and Liquid might be used with advantage; and in the case of fruits a good syringing night and morning with hot water would doubtless be sufficient.

APHILOTHRIX GEMMÆ. *See* **Oak Galls.**

APHLOIA (from *a*, privative, and *phlois*, bark; alluding to a peculiarity of one of the species, called by the French colonists Bois sans Écorce). ORD. *Bixineæ*. A small genus (three species) of stove, evergreen trees or shrubs, natives of the Mascarene Islands. Flowers hermaphrodite, axillary, sessile or shortly pedicellate; sepals four or five, broadly imbricated; petals wanting; stamens numerous. Leaves entire, serrated or toothed. Only one species calls for mention. For culture, *see* **Ludia.**

A. mauritiana (Mauritian). The correct name of *Ludia heterophylla.*

APHYLAX. A synonym of **Aneilema** (which *see*).

APIACEÆ. Lindley's name for the **Umbelliferæ** (which *see*).

APIS MELLIFICA. *See* **Honey Bee.**

APISTA. A synonym of **Podochilus** (which *see*).

APIUM. Petals entire; umbels compound. Leaves dissected. In addition to the Celery (*A. graveolens*) and Celeriac (*A. g. rapaceum*), the following variety may be mentioned:

A. graveolens tricolor (three-coloured). *l.* glossy green, striped down the centre with a silvery-grey band, and margined with creamy-white. 1882.

APLOCARYA. A synonyn of **Dolia** (which *see*).

APLOPAPPUS. *See* **Haplopappus.**

APLOPHYLLUM. Included under **Ruta** (which *see*).

APODOLIRION (from *a*, privative, *podos*, a foot, and *Lirion*, a Lily; in allusion to the peduncles being short and hidden). ORD. *Amaryllideæ*. A genus embracing half-a-dozen species of greenhouse, bulbous plants, natives of South Africa. Flowers white or reddish, as large as a Crocus; perianth funnel-shaped, with a long tube and six sub-equal, ascending segments; stamens in two rows near the throat; peduncle short, hidden in the neck of the bulb, one-flowered. Leaves narrow, not usually produced with the flowers. Only two species call for mention here. They thrive in a mixture of sandy loam and peat, and may be propagated by offsets or by seeds.

A. Ettæ (Miss Etta Stainbank's). *fl.*, perianth tube 3in. long, the limb white, tinged with red, 1in. to 1¼in. long; anthers in two superposed rows. *l.* (and bulb) like those of a Crocus. 1894.

A. lanceolatum (lance-shaped). The correct name of *Gethyllis lanceolata.*

APONOGETON. SYN. *Spathium* (of Edgworth). *Ouvirandra* (see p. 535, Vol. II.) is included by Bentham and Hooker under this genus, which comprises about a score species of stove, greenhouse, or half-hardy, scapigerous, submerged, Aquatic herbs, inhabiting tropical and temperate Asia and Africa, and Australia. Flowers white, or rarely pink or violet, hermaphrodite, spicate; perianth segments (or bracts) two or three, rarely one or wanting, petaloid; spikes solitary or twin, sessile at the apex of the scape. Leaves long-petiolate, oblong or linear, erect or swimming.

In the Lattice-leaf Plant, *A. fenestrale*, lovers of tender Aquatic Plants have a gem which well repays for the extra attention its culture entails. The treatment, according to Mr. Baker, of the Oxford Botanic Gardens, is as follow: In order to produce a luxuriant growth it must not be included in a tank with Aquatics that require abundance of light and sunshine. A tub, about 3ft. in diameter and 1½ft. in depth, is a very suitable receptacle in which to cultivate it. This should be situated in a warm plant-house in a position where the light can be subdued and the temperature of the water maintained at from 60deg. to 65deg. in the winter, and from 70deg. to 75deg. during the summer months. A suitable compost consists in good fibrous loam, a little leaf-soil, with a good sprinkling of coarse silver sand. An 8in. or 10in. pot is sufficiently large to accommodate a good-sized specimen, and the soil should be pressed firmly into the pot, afterwards covering the surface with small white stones or spar, to keep the soil from rising in the water: these also serve another purpose, by displaying to better advantage the formation of the leaves. The crown of the plant should be submerged about 2in. beneath the surface of the water. It is most important that the water be clean and as free from sediment as possible, rain-water being far preferable; further, it should not be allowed to become stagnant, or confervoid growths will make their appearance, and injure the plant. To prevent this as far as possible, some of the water should be drawn off about once a week by means of a siphon, and the tub filled up with fresh water of about the same temperature. If this does not check their appearance, a good method is to cover up the plant and exclude all light for a few days, when the confervoid growths may be easily syringed off and flushed over the rim of the tub. It is beneficial to the plant for the tub to be filled to overflowing by adding a little fresh water every day by means of a watering-can with a fine rose; or the same result may be attained (excepting that there is a continual slight agitation of the water) by a constant drip conducted by means of a siphon from another vessel situated at a higher level. This will cause the water to run over at the sides, and any dirt that may have become deposited on the surface will be thus removed.

Aponogeton—*continued.*

The propagation of the Lattice-leaf Plant is effected by means of divisions of the root-stock and also by seeds. It is rather a capricious subject to cultivate, for treatment that suits it in one place sometimes disagrees with it in another, which perhaps may be owing to foreign matter held in suspension by the water. As is the case with many other plants, its successful cultivation greatly depends on apparently trifling details, but a well-grown specimen is a unique object of beauty, deserving all the attention that can be bestowed upon it.

To the species described on p. 93, Vol. I., the following should be added:

A. angustifolium (narrow-leaved). *fl.* pale red; bracts white; stamens six; spike bifid, few-flowered. July. *l.* linear-lanceolate, submerged, opaque, variable in size. South Africa, 1788. (B. M. 1268.)

A. distachyon Lagrangei (Lagrange's). A form with white and rosy-flesh-coloured bracts, flushed with green at the base. 1895. (R. H. 1895, p. 380.)

A. d. monostachyon (single-spiked). The correct name of *A. monostachyon.* (A. B. R. 46.)

A. d. roseum (rosy). A charming variety, having rosy-tinted flowers. 1885.

A. fenestrale. This is the correct name of the plant described as *Ouvirandra fenestralis.*

APORIA CRATÆGI. *See* **Lepidoptera.**

APORUM. Included under **Dendrobium** (which *see*).

APPENDAGE. Any superadded or subordinate part; *e.g.*, thorns, hairs, &c., on a stem.

APPENDICULA (from *appendix;* in allusion to the appendage at the base of the lip). SYNS. *Conchochilus, Metachilum.* ORD. *Orchideæ.* A genus embracing about a score species of stove, epiphytal Orchids, with tufted, leafy stems, natives of tropical Asia, Australia, and Polynesia. Flowers usually minute; sepals connivent, the lateral ones connate at base and adnate to the produced foot of the column, forming a mentum; petals variable; lip erect, inserted on the foot of the column or with its sides adnate thereto; column very short, the rostellum erect, bifid. About four species have been introduced, but they are of no horticultural value.

APPLE. Since the work was issued the following are some of the most noteworthy introductions and additions:

Allen's Everlasting. Dessert. Fruit medium; flavour very good. It succeeds best as a bush or pyramid tree. April and May.

FIG. 53. ALLINGTON PIPPIN APPLE.

Allington Pippin. Dessert. Fruit medium, yellow, with red streaks on the sunny side; flavour very rich and agreeable. November to January. A promising new variety. See Fig. 53.

American Mother. *See* **Mother.**

Baumann's Red Winter Reinette. Dessert or Kitchen. Fruit rather large, flatish round; skin nearly covered with a brilliant deep-red, intensified on the exposed side. April and May. The tree is a good grower and a free bearer, but of second-rate flavour. See Fig. 54

FIG. 54. BAUMANN'S RED WINTER REINETTE APPLE.

Beauty of Bath. Dessert. Fruit medium, beautifully coloured, and of handsome shape; flavour rich and agreeable. Good bearer; one of the best early dessert apples. July and August.

Belle de Pontoise. Kitchen. Fruit large, somewhat approaching a Blenheim in shape, and highly coloured. A variety of much promise. Great bearer; small trees fruiting freely. December to April.

Bismarck. Kitchen. Fruit large, richly coloured, and of fine shape. A new variety from Tasmania, and one which has already proved a decided acquisition, being an enormous bearer hardy, and vigorous. October to January.

Blenheim Orange. *See* **Blenheim Pippin.**

FIG. 55. BLUE PEARMAIN APPLE.

Blue Pearmain. Dessert. Fruit over medium size, inclined to be conical; skin green, flushed with red on the exposed side, and covered with a delicate blue bloom similar to that of a black grape. A new variety of delicious flavour, keeping sound until May. The tree is a moderate grower, but has not yet proved free-bearing. See Fig. 55.

Bramley's Seedling. Kitchen. Fruit very large, rather flat, solid; first-class for cooking. Good bearer, succeeding equally well as a bush or as a standard. December to May. See Fig. 56.

Byford Wonder. Kitchen. Fruit very large, palé yellow, solid; great bearer. February and March.

D. T. Fish. This is now regarded as synonymous with **Warner's King** (which *see*).

Early Peach. Dessert. A compact-growing and more prolific form of the well-known **Irish Peach Apple** (which *see*). August

Early Rivers. Kitchen. Fruit large, firm. A good bearer. July and August. A fine, early, cooking apple.

Ecklinville Seedling. Kitchen. A very large, handsome variety, of good shape; a splendid cooker, and an extraordinary bearer on all forms of trees. See Fig. 57.

Apple—*continued.*

FIG. 56. BRAMLEY'S SEEDLING APPLE.

Gascoigne's Scarlet Seedling (SYN. *Glory of England*). Kitchen or Dessert. Fruit large and beautifully coloured; very crisp and pleasant in flavour. Great bearer. November to February.

Glory of England. *See* **Gascoigne's Scarlet Seedling.**

FIG. 57. ECKLINVILLE SEEDLING APPLE.

Golden Noble. Kitchen. Fruit large and handsome, of a rich golden colour. A constant and prolific bearer. November and December. This is a fine variety, and distinct from Waltham Abbey Seedling, which is sometimes sold for it. See Fig. 58.

FIG. 58. GOLDEN NOBLE APPLE.

Apple—*continued.*

Golden Spire. Kitchen. Fruit large, conical, straw-coloured; a first-rate cooker, and a constant and heavy bearer, far superior to the old Keswick Codlin, whose place it should take. August to November. An excellent market variety.

Grenadier. Kitchen. Fruit large, yellow, crisp, and sub-acid. Constant and good bearer. September and October.

Hambling's Seedling. Kitchen. Fruit large and handsome, green, flushed with red on the sunny side; flesh firm and of good flavour, and useful for dessert in season of scarcity. December to April.

King of Tompkins Co. Dessert. Fruit large and handsome, richly coloured on the sunny side; flavour very good and sweet. Good bearer on the Paradise stock, and only suited for bush or wall trees. November to March.

Lady Sudeley. Dessert. Fruit medium, bright red, except where shaded; flesh soft, crisp, and highly-flavoured if eaten as soon as ripe. Good and constant bearer. August and September. This variety should not be heavily pruned, as the finest fruits are produced at the points of the shoots.

FIG. 59. LANE'S PRINCE ALBERT APPLE.

Lane's Prince Albert. Kitchen. Fruit large, and of perfect shape, one of the firmest and heaviest apples, with crisp and pleasant flavour. An enormous bearer. November to May. This variety is specially suited for small gardens, as it crops most profusely on bush trees. One of the best market apples. See Fig. 59.

Loddington Seedling. *See* **Stone's Apple.**

Margil. Dessert. Fruit medium, red on the sunny side; flavour crisp and delicious. October and November. This variety answers best on warm soils, and on the Paradise stock.

Mother (SYN. *American Mother*). Dessert. Fruit above medium size, highly-coloured on the sunny side; flavour sweet and very crisp. September and October. One of the finest dessert apples on warm soils. A good bearer on bush trees.

Newton Wonder. Kitchen. Fruit large, and of good shape, flushed on the sunny side with red; flavour sub-acid and brisk.

FIG. 60. NEWTON WONDER APPLE.

EUCRYPHIA PINNATIFOLIA.

Apple—*continued.*

November to May. It is a sturdy grower, great bearer, very heavy, and will prove a valuable market apple. See Fig. 60.

Pearmain, Christmas. Kitchen. Fruit medium, rich colour, and pleasant, crisp flavour; equally good for dessert. Great bearer. November to January. A promising new variety.

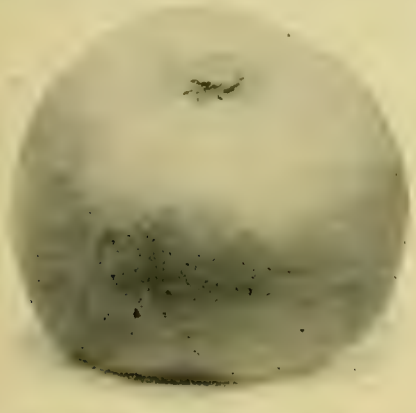


FIG. 61. PEASGOOD'S NONSUCH APPLE.

Peasgood's Nonsuch. Kitchen. Fruit very large, of perfect shape, and fine colour; flavour very brisk and agreeable. Moderate bearer. October to December. The most imposing and finest exhibition apple, but a spreading grower, and should not be closely pruned. See Fig. 61.

Potts' Seedling. Kitchen. Fruit large, of a pale straw colour; flesh soft, crisp, and juicy. A great and constant bearer. August to October. The best variety for town gardens or smoky districts.

Queen Caroline (SYN. *Spencer's Seedling*). Kitchen. Fruit medium to large, of perfect shape, yellow, with minute brown spots all over; flavour sub-acid and juicy. A good bearer and compact grower. October to December.

Roundway Magnum Bonum. Dessert. Fruit medium, russety; flavour excellent. Good bearer. November to March.

Russet, Egremont. Dessert. Fruit medium, and of good shape; flavour rich and crisp. Good bearer and compact grower. October to December. This is the best of the Russet class.

Sandringham. Kitchen. Fruit large, greenish; flavour brisk. Good bearer. November to January.

Spencer's Seedling. *See* **Queen Caroline.**

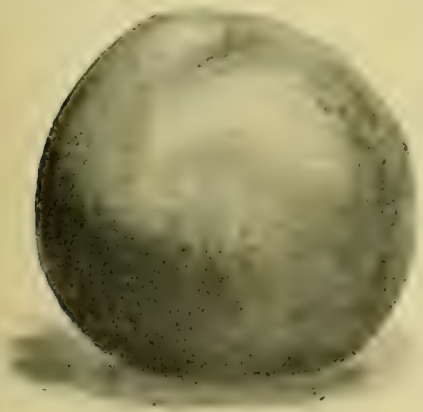

FIG. 62. STIRLING CASTLE APPLE.

Stirling Castle. Kitchen. Fruit large, green, firm; flavour brisk and excellent for cooking. An extraordinary bearer, and most suitable for growing as a bush tree. October to December. See Fig. 62.

Stone's Apple (SYN. *Loddington Seedling*). Kitchen. Fruit large, yellow, flushed with red, firm; flavour sub-acid and crisp. Good bearer August to December. A splendid variety for bush or standard trees.

Apple—*continued.*

The Queen. Kitchen. Fruit large, flat, covered with red stripes, firm, and of good flavour. Good bearer. October to January.

Tyler's Kernel. Kitchen. Fruit large, conical, bright red on the sunny side; flavour rather acid. Great bearer on established standard trees December to February.

FIG. 63. WEALTHY APPLE.

Wealthy. Kitchen or Dessert. Fruit medium, handsome form, and fine red colour. Good bearer on bush trees. October to December. An American variety, of rich flavour. See Fig. 63.

White Transparent. Kitchen or Dessert. Fruit medium, conical, of a beautiful straw colour, flesh soft; flavour brisk and very juicy. A great and constant bearer. July and August. This is one of the finest early apples, and valuable for market.

For Cordons the best are: ALLEN'S EVERLASTING, BEAUTY OF BATH, BELLE DE PONTOISE, BISMARCK, COX'S ORANGE PIPPIN, ECKLINVILLE SEEDLING, EGREMONT, GOLDEN SPIRE, HAWTHORNDEN, LANE'S PRINCE ALBERT, LORD SUFFIELD, MARGIL, MOTHER APPLE, NEWTON WONDER, POTTS' SEEDLING, QUEEN CAROLINE, RIBSTON PIPPIN, RUSSET, STIRLING CASTLE, and WHITE TRANSPARENT.

For Pyramidal, Bush, and Espalier Trees the following are all of proved merit: ADAM'S PEARMAIN, ASHMEAD'S KERNEL, BEAUTY OF BATH, CORNISH GILLYFLOWER, COX'S ORANGE PIPPIN, EARLY PEACH, EGREMONT RUSSET, IRISH PEACH, JAMES GRIEVE, KEDDLESTONE PIPPIN, KERRY PIPPIN, KING OF THE PIPPINS, KING OF TOMPKINS CO., LADY SUDELEY, MARGIL, MOTHER APPLE, RED INGESTRE, RED QUARRENDEN, RHINETTE DU CANADA, RIBSTON PIPPIN, ROUNDWAY MAGNUM BONUM, ROSS NONPAREIL, SCARLET NONPAREIL, STURMER PIPPIN, SYKE HOUSE RUSSET, WEALTHY, and WINTER QUEENING..

The following are Kitchen sorts, well adapted for this restricted method: ALFRISTON, BEDFORDSHIRE FOUNDLING, BELLE DE PONTOISE, BISMARCK, BRAMLEY'S SEEDLING, BYFORD WONDER, COX'S POMONA, DUCHESS OF OLDENBURGH, DUMELOW'S SEEDLING, ECKLINVILLE SEEDLING, GASCOIGNE'S SCARLET SEEDLING, GOLDEN NOBLE, GOLDEN SPIRE, LANE'S PRINCE ALBERT, LORD SUFFIELD, MANX CODLIN, NEWTON WONDER, NEW HAWTHORNDEN, PEASGOOD NONSUCH, POTTS' SEEDLING, QUEEN CAROLINE, SANDRINGHAM, STIRLING CASTLE, TOWER OF GLAMMIS, TYLER'S KERNEL, WARNER'S KING, and WHITE TRANSPARENT.

For Standard Trees, or Orchard Planting, the following are excellent varieties: ALFRISTON, ALLINGTON PIPPIN, BEAUTY OF BATH, BELLE DE PONTOISE, BESS POOL, BISMARCK, BLENHEIM ORANGE, BRAMLEY'S SEEDLING, BYFORD WONDER, COX'S POMONA, DUKE OF DEVONSHIRE, DUMELOW'S SEEDLING, ECKLINVILLE SEEDLING, GASCOIGNE'S SCARLET SEEDLING, GOLDEN NOBLE, GOLDEN SPIRE, LADY HENNIKER, MÈRE DE MÉNAGE, NEWTON WONDER, PEASGOOD'S NONSUCH, POTTS' SEEDLING, TOWER OF GLAMMIS, TYLER'S KERNEL, WARNER'S KING, WEALTHY, WINTER QUEENING, and WORCESTER PEARMAIN.

For Cold and Exposed Situations: ALFRISTON, BRAMLEY'S SEEDLING, CLAYGATE PEARMAIN, ECKLINVILLE SEEDLING, DUKE OF DEVONSHIRE, FRENCH CRAB, GOLDEN SPIRE, KESWICK CODLIN IMPROVED, MANX CODLIN, NEWTON WONDER, NORTHERN GREENING, STURMER PIPPIN, TOWER OF GLAMMIS, and WARNER'S KING.

For Cottage Gardens: BISMARCK, BRAMLEY'S SEEDLING, DUCHESS OF OLDENBURGH, ECKLINVILLE SEEDLING, GOLDEN SPIRE, KING OF THE PIPPINS, LANE'S PRINCE ALBERT, NEW HAWTHORNDEN, POTTS' SEEDLING, STIRLING CASTLE, WHITE TRANSPARENT, WINTER STRAWBERRY, and WORCESTER PEARMAIN

APPLE AND PEAR BLIGHT.—All sorts and conditions of trees are popularly supposed to be susceptible to "blight." The name has been handed down from the Dark Ages to indicate certain conditions of plants, such as those which have died away almost entirely as if blasted, but the true cause of which to the average individual is obscure. By many certain atmospheric conditions are thought to be entirely due to blight; while in country places, Aphides are collectively spoken of as blight. Fungi, strange to say, though frequently the cause of decay in trees, are less often suspected. Indeed, there are very large numbers who will not believe that the condition, generally known as Canker in Apple Trees, is due to a most insidious fungus, which finds its way into bark wounds and quickly spreads.

In North America, however, there is a condition of Apple and Pear Trees which has earned for itself the popular appellation above adopted. It is due to a most destructive disease, supposed to be brought about by the presence of bacteria. Apple and Pear Trees are commonly attacked; but the disease by no means restricts itself to such, being found upon many of the ornamental species of the genus *Pyrus* and its very near allies. Burrill, of Illinois, made some extensive investigations, and published the result of such in the "American Naturalist" of 1881, He has been followed by several able workers in the same field, one of the most exhaustive reports appearing in the "Year Book of the United States' Department of Agriculture for 1895." It was contributed by Mr. Warlie. Still, it cannot be said for certain that Apple and Pear Blight is due to bacteria.

The indications are first seen on the bark. They are small dead patches, which increase rapidly in size, and involve maybe the whole of the tree. There is a wholesale exudation of the sap, and trees so attacked present a most unhealthy appearance, what with the dead portions and the partial or entire defoliation which occurs. Hartig says that "the disease appears to bear resemblance to the tree-canker produced by *Nectria ditissima*, and as in the case of this fungus, large numbers of small gonidia, resembling bacteria, are produced in the cortex." Though the disease is at present confined to America, it is of such a virulent nature that its chief symptoms, at any rate, should be known to pomologists. Removal and burning of the diseased portions is the way to prevent the spread of the disease.

APPLE APHIS (*Aphis mali*). *See* **Aphides.**

APPLE-BARK BEETLE (*Xyleborus dispar; Bostrichus dispar*). Under this somewhat inappropriate name are known in gardens some destructive little Beetles of a dark brown or, in some cases, of an almost black colour, found upon Apple, Pear, Plum, and other trees. The injury they do is considerable, though the work of destruction is not in evidence until the affected branches or stems are opened, disclosing the numerous galleries. These galleries if examined will be found coated with a whitish substance, out of which grows a fungus, upon which they feed; this is called Ambrosia. The Beetles differ considerably as to size and form, the females (⅛in.) being much larger than the males, which are not as often in evidence. It is only of recent years that this species has appeared in sufficient numbers to be troublesome. The insects are on the wing in late spring, and the female then selects a suitable branch in which to bore and deposit her eggs. Both young and old, healthy and weakly, trees are selected; and the Beetles may be suspected if the shot-like holes (responsible for the very appropriate name of "Shot-Borers") are noticed. Such holes are really the exits from their galleries, just as are the so-called "wormholes" of another destructive Beetle, commonly found in furniture.

Beetles which feed protected in the interior of tree-trunks and branches are not readily reached by the

Apple-Bark Beetle—*continued.*

ordinary insecticides. In America, where the Beetle is terribly destructive, the stopping up of their exit-holes is recommended, using a wash made of soft soap and a strong solution of washing soda in water of the consistency of paint. This (says the Report of the Entomologist to the Canadian Agricultural Department) should be applied on the morning of a warm day, when it will dry in a few hours, forming a tenacious coating.

APPLE-BLOSSOM WEEVIL (*Anthonomus pomorum*). Though small (about 5mm.) this insect (Fig. 64) is very destructive at times to the unexpanded blossom buds of Apple and Pear in early spring. Notwithstanding the number of improved methods for coping with certain Beetles which have been introduced within recent years, there is no better way of dealing with this pest than by shaking or jarring infested trees, killing all the Beetles which are found, and *burning* all withered blossoms, as such are likely to contain the insect in some stage of its existence. In winter, too, the old bark may be removed and burnt, and the trunk sprayed with the potash and soda preparation advocated for **American Blight.** Where the soil can be constantly moved it is of great benefit to allow poultry to run amongst the trees, and if these are vigorously shaken while the larvæ are in the blossoms numbers will be dislodged and be devoured by the poultry.

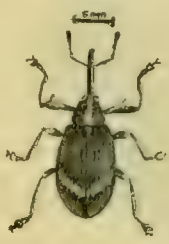

FIG. 64. APPLE BLOSSOM WEEVIL (*Anthonomus pomorum.*)

APPLE GALL. *See* **Vine Galls.**

APPLE, GOLDEN. *See* **Ægle.**

APPLE MAGGOT (*Trypeta pomonella*). This insect has only within recent years asserted itself in numbers. It belongs to the *Diptera*. In America it is one of the pests which Apple-growers have to reckon with, and in some seasons it has proved very destructive. In appearance the perfect insect might well pass for a small house-fly, were it not that its brilliant and prominent eyes at once differentiated it from that household pest. The general body-colour is black, with whitish dots and bands, which latter also traverse the wings. The female may be distinguished from her mate by the flat ovipositor.

These small insects are upon the wing in early summer. The Apples are at that time of good size. The eggs are laid one at a time, the female piercing the skin of the fruit with her sharp ovipositor; and as she is estimated to lay on the average some 300 or 400 eggs, the amount of harm a few of these flies is capable of working may be readily recognised. The eggs hatch out in from four to six days, and the larvæ are full-fed in about as many weeks. They at once begin to feed upon the food ready to hand, and the work of the half-grown maggots is well shown in Fig. 65, *a*. When mature they assume the chrysalis state, either just beneath the surface of the ground, or frequently, in the case of stored fruit, in the bins or barrels, emerging as perfect insects at the time stated. The insects are difficult to combat, and recourse must be had to preventive measures, such as the collection of all fallen fruit, and the burning of all accumulations from bins, barrels, and store-rooms. Those interested in the study of this insect will find it fully dealt with by Professor F. L. Harvey, in the Annual Report of the Maine Agricultural Experiment Station in 1890, and two of whose admirable figures are here reproduced. See Fig. 65.

APPLE OR CODLIN MOTH (*Carpocapsa pomonella*). Everyone practically is acquainted with the maggoty condition of Apples, for which the Codlin Moth is

Apple or Codlin Moth—*continued.*

responsible, though many are still unacquainted with the perfect insect itself. The Codlin Moth, though usually found on the Apple, is not over particular, as it has been recorded from Pears, Plums, Apricots, Peaches, Spanish Chestnuts, and even Walnuts. This last, did it not emanate from so sterling an entomologist as Mr. Adkin, many, perhaps, would be inclined to doubt. In some countries this insect is double-brooded; but here, happily, it is single-brooded.

From time to time all sorts of methods have been suggested for dealing with the Codlin Moth, but none so effective as spraying with Paris Green, and if used with care there is no danger. That this arsenite is a virulent

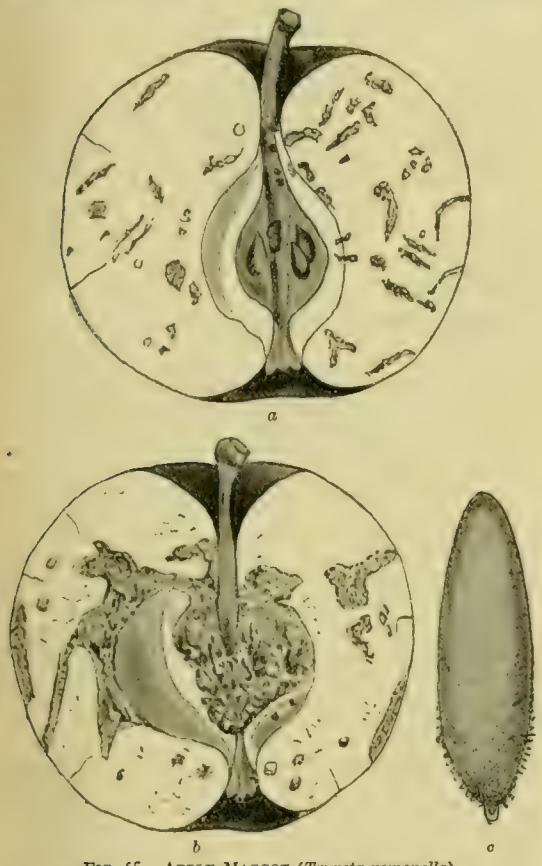

FIG. 65. APPLE MAGGOT (*Trypeta pomonella*).
a, Work of Half-grown Larvæ; *b*, Full-grown Larvæ (Natural Size); *c*, Egg (Greatly Enlarged).

poison cannot be too widely known, any more than can its utility in destroying this pest of the orchard and the garden. Dwarf trees are, of course, the easiest to deal with; but standard trees might also be reached with a good machine. The great things to remember are to use the Paris Green in the proportion of 1oz. to 20gall. of water, and to spray as soon as the blossoms have fallen. Paris Green may be procured from some firms mixed into a kind of paste; this is safer for mixing than the dry powder. Spraying with Paris Green should be in combination with cleanliness about the garden, the use of haybands (as advocated in Vol. I.), and the periodical cleansing of the trunk in winter. Even where cattle are grazing, the arsenite in the proportions suggested may be employed with safety. As a means of prevention, all fruits which show signs of infestation should be burned.

APPLE MUSSEL SCALE (*Mytilaspis pomorum*). This very common brown Scale is rather difficult to deal with when once it has attached itself to its food-plant. It is one of the most familiar pests to the fruit cultivator, by reason of the peculiar form of the covering, or scale, (Fig. 66), which has been exuded by the mother insect. The Scales are sucking insects, and are best therefore killed by contact. A Californian grower (Mr. Maxwell Heron) recommends the following winter treatment: Take 25lb. of unslaked lime, 20lb. of sulphur, 15lb. of salt, and 60gall. of water. Place 10lb. of the lime and all the sulphur with 20gall. of water in a copper, and boil until all the sulphur is dissolved. Then take the remainder of the lime and the salt, slake it, and add enough water to make 60gall. Apply this when warm through a syringe, keeping the mixture well stirred. If this be used, he says, when the tree is dormant, it is perfectly harmless to the buds. In addition to its value as an insecticide it is of benefit as a fungicide. The mixture may, of course, be made in smaller quantities, so long as the due proportions are observed. As before stated, once the insect has attached itself to the bark it is difficult to dislodge, on account of its protective covering. In winter, too, when the trees are dormant, great benefit will be derived by spraying with potash and caustic soda, as advised for **American Blight.**

FIG. 66. APPLE MUSSEL SCALE.

The best time to fight it is in late spring (May), when the young insects are on the wander. Then a soapy wash containing a little tobacco water will be found of great benefit. So, too, would a weak solution of kerosene emulsion.

Gishurst's Compound Soap is a most effective Scale insecticide, employed at the rate of 4oz. to 1gall. of water. Hot water of a temperature of 150deg. may also be successfully used in the spring, and is perfectly safe. Of recent years cyanide of potassium fumes have been recommended for Scale, but this insecticide cannot be generally recommended on account of its dangerous nature.

The Apple Mussel Scale (so-called) is identical with the Oyster Shell Bark Louse, which gives such trouble to American fruit-growers. Curtis's old name for this insect, *Aspidiotus conchiformis*, is now regarded by scientists as a useless synonym. Though usually associated with the Apple, this species is a very general feeder, and may be found upon Pears, Currants, Raspberries, and many of the hardy outdoor shrubs, such as Cotoneasters and Heaths. It undoubtedly, however, shows a marked partiality for Apples; hence the origin of the popular name.

APPLE POWDERY MILDEW. This disease has not yet been recorded in this country; but in America it causes the fruit-grower considerable loss. The fungus responsible for the mischief is *Podosphæra oxyacantha*. It is a mildew not far removed from the familiar *Sphærotheca pannosa* on Roses. The foliage of young Apples is chiefly attacked, and their whole surface is covered. The fungus has a very debilitating effect upon the trees. The area of infection is rapidly increased by means of the conida, or summer spores; while winter spores are also

Apple Powdery Mildew—*continued.*

produced, and these carry it over the winter. Many other *Rosaceæ* are attacked by this undesirable fungus-visitor to a nursery or plantation of young trees—Cherry, Peach, Hawthorn, Mountain-Ash, and Medlar. Stems as well as leaves are coated with the mildew. In very bad attacks the foliage is shed prematurely, and the seedling plants make little or no progress. All affected leaves should be collected and burnt; while, as soon as the disease is noticed, the trees should be treated to a solution of sulphide of potassium (1oz. to 3gall. of water).

APPLE ROT. This condition of Apples must be familiar do everyone, though its causes are to the majority obscure. It is, however, due to a well-characterised fungus —*Glœosporium fructigenum.* Popularly the disease is known as Apple Rot; but it is not restricted to that fruit, being found upon Pears, Peaches, Plums, &c. Sometimes it is called Ripe Rot, or Bitter Rot (the latter being a peculiarly appropriate name). Usually it is only observed by growers after the fruits have fallen, when perhaps nearly full-grown; or, may be, it is not observed until some time after the fruits have been stored. Frequently, however, Apples are attacked when comparatively young, and the disease not being readily noticed—at any rate, in the case of standard trees—it rapidly spreads. All parts of the fruits are liable to attack, though, as is the case with several other diseases, the calyx end is first involved. The symptoms, even at the outset, are fairly well marked, as the fruits are spotted with brown. The spots increase in size and coalesce as growth proceeds, and give place to large patches. If the disease is allowed to run, a very large proportion of the crop will be contaminated, and its market value will be practically nil. As the disease progresses, blackish pustules are formed over the whole surface of the skin; these rupture and release the spores, which increase the trouble. Inside the condition of the fruit is still worse, for the mycelium has completely broken down the tissues, and the familiar rotten condition and bitter taste are the result.

Once the disease has attacked the fruits, all Apples showing symptoms of the fungus should be removed and burnt before they arrive at that stage when the spores will be scattered by various agencies. All that is practical is to prevent the further spread of the disease, which is best done by spraying the trees at intervals with either Bordeaux Mixture or sulphide of potassium (1oz. to 3gall. of water). All fruits which fall and show signs of spotting should be burnt. In the case of Apples stored, it will be very necessary to go over them frequently, destroying all that are "spotted," as the disease spreads just as rapidly, under favourable conditions, when the fruits are off the trees. In America the disease assumes even more serious proportions than here.

APPLE SAWFLY (*Hoplocampa testudinea*). Though not as well known as many of the insects which infest fruit trees, yet the creature under notice is at times exceedingly troublesome to gardeners. Frequently, however, its depredations are put down to other insects, especially to the Codlin Moth. There are ten species of this genus found in Britain, but only the one above-named calls for notice here. The perfect insects are only about 12mm. in wing-expanse, and of a reddish-yellow colour. They are on the wing in early spring, the female depositing her eggs in the blossoms of the Apple. In due time the grubs hatch out, and make their way into the young Apple. Outwardly there is no indication of the presence of these pests, and it is not until the fallen immature fruits are examined that the depredators are disclosed.

All such Apples as fall early should be at once collected and burned. If left on the ground undisturbed, as they

Apple Sawfly—*continued.*

not infrequently are, the grubs, about the first week in July, eat their way out and pupate in the ground in cocoons.

Prevention is the only method of dealing with this pest. It is of little use attempting to treat the trees to an insecticide at such a season as the Sawflies themselves are on the wing, as the blossoms would be injured thereby, and the crop further endangered.

By some entomologists this insect is known as *Tenthredo testudinea.*

APPLE AND PEAR SCAB (*Fusicladium pyrinum; F. dendriticum*). These very common pests to Pears and Apples are responsible for the condition known as "Cracking," and they have been dealt with at considerable length. (*See* **Pear-Fungi.**) At the time the article was written, however, the disease had baffled alike the grower and the scientist, and the loss to the former through the produce being rendered unsightly, and thus unsaleable, was enormous. More recent investigations have conclusively shown that the disease may be combatted, like many others of a similar character, by the judicious use of **Bordeaux Mixture** (which *see*). This fungicide to be effective must be sprayed on directly the new leaves are in evidence, using a very weak solution. The spraying should be repeated at intervals of three weeks, or a little less, until the fruit is formed. Leaves and shoots are also attacked.

APPLE-SHOOT MOTHS (*Laverna vinolentella; Argyresthia curvella*). The first species, a small moth under ½in. in wing-expanse, is now and again responsible for a deal of damage to Apple shoots. It must be classed as local and uncommon. In the Caversham district in 1898 it was very prevalent, and was most injurious to the young Apple trees there planted. The Moth is black, and has two deep black erect tufts of scales on each fore-wing. During the day it is not often seen, as then it sits upon the Apple trunks and branches, appearing on the wing towards sunset. The eggs are laid in July and hatched out in spring, the larvæ entering the shoots, causing them to die away. Directly this is noticed, all such dead shoots should be cut away and burned.

Argyresthia curvella is a trifle larger than the first-named species, and commoner, though by no means abundant. It is on the wing during June and July. The fore-wings are white, strigulated with a darkish brown, while there are a small, transverse dorsal mark, a narrow band from the middle of the costa to the centre of the back, and an irregularly-shaped dark blotch towards the apex of the wings. The hind-wings are grey. At rest these Moths appear as if standing on their heads, by reason of the fact that the hinder part is obliquely raised from the surface. The larva is hatched in May, and feeds in the shoots, which should be treated similarly to those attacked by the *Laverna* above noted.

APPLE-SUCKER (*Psylla mali*). Belonging to the same natural order (*Homoptera*) as the Aphides, or Plant Lice, is the destructive little creature above-named. Of recent years it has been very abundant wherever Apples are grown, and it has taxed the ingenuity of the most practical fruit-grower to keep it in check. In Germany it is a still greater pest. The insects extract the juices from their food-plants, hence the common name. The generic name (*Psylla*) is in allusion to the leaping power of the perfect insect.

The Apple Sucker is on the wing in late spring, but is so minute (2mm.) that it may readily escape observation. At pairing time it varies considerably as to colour—being green, with brownish-red, yellow, or red markings. The eggs are usually deposited singly, but sometimes in pairs, on the young twigs. The larvæ emerge in about a fortnight, and commence to feed upon the

Apple-Sucker *continued.*

unexpanded buds, at the same time covering them with a kind of sticky globules, popularly, but wrongly, described a "honeydew." This secretion, together with the excrement, quite prevents the buds from developing, especially if the season be a dry one. Between the deposition of the egg and the emergence of the perfect insect about a month elapses. During that time the larva changes its skin five times. At the end of the third moult the wings are plainly discernible, as shown in the

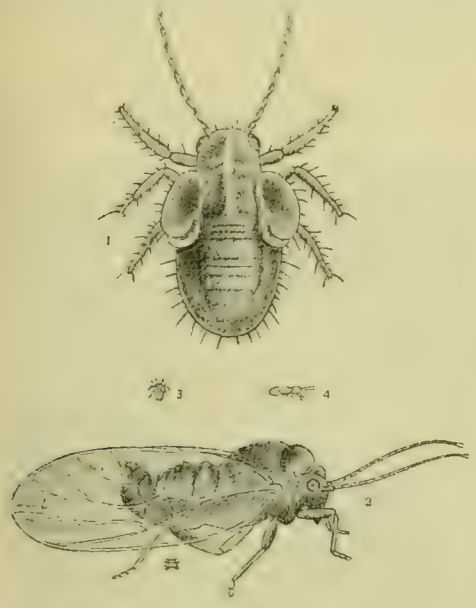

FIG. 67. APPLE SUCKER (*Psylla mali*), showing: 1, Larva (Magnified 14 diam.); 2, Perfect Insect (Magnified 10 diam.); 3, Larva (Natural Size); and 4, Perfect Insect (Natural Size).

illustration (Fig. 67). In the mature insect the wings are disposed roof-like, as shown in the illustration (Fig. 67). Those perfect insects which are to carry on the cycle of existence pass the winter under the bark of the tree.

Trees which are attacked soon show unmistakable symptoms. The foliage assumes a most unhealthy yellowish-green colour, and not infrequently prematurely falls. The blossom-buds also fail to set, and are shed in quantities.

By way of remedies the grower must depend entirely upon spraying, for which there is nothing equal to weak kerosene emulsion. This should be applied in April, directly the leaves show signs of opening. Several applications may be necessary throughout the season, for so far as at present is known the eggs are impervious to what may be termed safe insecticides. As an additional precaution the trees should also be similarly treated in winter, and all prunings should be burnt.

APPLE-TREE CANKER. *See* **Canker.**

APPRESSED, ADPRESSED. Lying close, *e.g.*, leaves Appressed to a stem.

APRICOT. To the varieties described in Vol. I., pp. 99-100, the following may now be added:

Alberge de Montgamet. A small, early, hardy, and prolific variety. Fruit deep yellow, fair flavour, and one of the best for preserving. Ripe at the end of July.

Beaugé. A late and good form of Moorpark. Ripe middle of September.

Apricot—*continued.*

D'Alsace. A glorified form of Moorpark. The fruit is larger, and equally as highly-flavoured. The tree is a vigorous grower, and not so liable to die away as Moorpark.

Early Moorpark. An early variety that ripens its fruit three weeks earlier than the original Moorpark, to which it is similar in growth and fruit. Ripe early in August.

Frogmore Early. Fruit small, deep orange in colour, with a good-flavoured flesh. Ripe early in July.

Golden Drop. One of the most delicious in flavour, with a rich melting flesh. Fruit small, deep orange in colour. As the trees acquire age they become very prolific. Ripe at the end of July.

Hemskerk. Somewhat similar to Moorpark, but the tree is hardier and more enduring. Ripe early in August.

La Délicieuse. A new variety from the East, stated to be of exquisite flavour.

Large Early. Fruit large, deep reddish-orange colour; flesh tender, melting, and richly flavoured. Ripe at the end of July.

New Large Early. A very early form of the Large Early.

Oullin's Early. An improved early form of Peach, but of larger size and exquisite flavour. An excellent free-bearing variety.

Pine Apple. Fruit large, deep yellow on the shaded side, and rich red cheek on the exposed side; flesh very tender, melting, and juicy, with a pleasing Pine-apple flavour. Ripe the middle of August.

Powell's Late. Fruit deep orange, flushed with red, large and abundantly produced; flesh sweet, juicy, and delicious. One of the hardiest and best varieties. Ripe early in September.

Roman. Fruit large, deep yellow, of brisk flavour; useful for preserving. A good bearer. Ripe the middle of August.

APRICOT WEEVIL, or RED-LEGGED GARDEN WEEVIL (*Otiorrhynchus tenebricosus*). If not as frequently met with in gardens as some of its near relatives, yet it is so destructive that every gardener should be familiar with it. Moreover, in certain parts of England (the south) it is a fairly common hedgerow insect. In the perfect state, this Beetle attacks all parts above ground of such trees as Apricots, Peaches, Nectarines, &c.; while the grubs sometimes damage the roots of Raspberries, Strawberries, and bush fruits like Currants. The Beetle (Fig. 68) is ½in. long, black, and covered with yellowish down. The legs are red.

FIG. 68. APRICOT WEEVIL (*Otiorrhynchus tenebricosus*).

Being nocturnal it is not often seen, for in the day-time it secretes itself in wall crevices, under rubbish, &c. Where its presence is suspected, the trees should be visited at night and shaken over a tar-covered paper. Like most other Weevils, this one drops readily on being disturbed, when it may be picked up and thrown into a vessel of boiling water. The necessity for filling up cracks and wall crevices will be obvious. *See also* **Otiorrhynchus.**

APTERA. This is one of the Natural Orders into which naturalists divide the important Class *Insecta*. The insects belonging thereto are very minute, soft-bodied creatures, destitute of wings, and with the mouth either mandibulate or imperfectly suctorial. The Order is again sub-divided into *Thysanura* and *Collembola*. None of the members of either sub-order call for extended notice, for though commonly found associated with garden produce they are perfectly harmless. Indeed, they may almost be considered useful scavengers, feeding as they do on the lower animal and vegetable life. The most familiar insects of the Order are those members of the *Collembola* which are capable of leaping, and on that account are popularly known as Springtails.

APTOSIMUM. The correct name of **Ohlendorffia** (which *see*).

AQUARTIA. Included under **Solanum** (which *see*).

AQUATIC PLANTS. No more beautiful phase of gardening can be named than the cultivation of Aquatics, though hitherto but little has been done by amateurs towards bringing this neglected group of plants into prominence. Some of the plants may be grown in very homely appliances, such as old barrels, cut in halves and sunk into the ground to within a few inches of their tops. For others large earthenware pans will suffice, so long as they are protected against frost. Of course, for the majority more elaborate vessels and culture are needed—large tanks (both indoors and outside), ponds, lakes, &c. The literature on the subject is scant, and for the bulk of the information here given we are indebted to Mr. W. G. Baker's (of Oxford) contribution to the "Book of Gardening."

Aquatic Plants—*continued.*

Figs. 69 and 70, is the great desideratum for exemplifying the admirable effects that can be produced by hardy Aquatic Plants when their cultivation is as skilfully undertaken as in the case of many other things. Even when everything has been carefully done that seems to be necessary to ensure establishing Nymphæas in large ponds or lakes, they are not then entirely free from casual mishaps. For instance, in a season of long-continued drought the water may sink to an abnormally low depth, and in receding from the plants leave their crowns exposed above its surface to endure an uncongenial element and its consequences.

In gardens where a natural lake or pond exists, provided it has an ample supply of water and an efficient outlet to prevent stagnation, a water garden might be formed, which, when judiciously planted, would become permanently

FIG. 69. THE LAKE AT KEW.

In numerous instances there may be already means at hand, in the form of tanks which have been constructed for the storage of water, that could be at once utilised for the reception of some of the many beautiful hardy Nymphæas now so readily obtainable; but it should be remembered that, excepting when the tank is of large dimensions, those of a neat habit will be preferable for this purpose to vigorous-growing kinds. The planting and arranging of them are largely discretionary, the use of tubs or boxes for the former being a matter of convenience, but in their arrangement, as far as practicable, the alternating of dark and light shades of colour may be generally depended on to produce a pleasing effect during their season of flowering. These observations are intended to apply to tanks already in existence.

The possession of ponds or lakes, such as shown at interesting and pretty, and in addition to providing a new feature, would impart additional beauty to the surroundings. It is not unusual to see a stagnant pond overgrown with rank vegetation that yearly adds to the decomposing mass of vegetable matter in its bed, yet there would probably be no great difficulty in converting a pond of this description into one of enduring prettiness. The margins and banks of streams afford excellent opportunities for establishing without much difficulty many plants that, in the course of time, would impart a pleasing effect to what might previously have been bare, uninteresting, or otherwise covered with indigenous coarse-growing vegetation.

Weeds should be removed as soon as they put in an appearance, for if allowed to become established, which they quickly do, some difficulty may be eventually experienced in eradicating them, and then not before they have either

Aquatic Plants—*continued.*

crippled the growth, or perhaps entirely destroyed other plants. In tanks, and also in ponds where there is but a slight current of water, various forms of confervoid algæ—green, thread-like vegetation, members of a low order of the Vegetable Kingdom—will sometimes make their appearance, more especially during warm weather; these, upon rising to the surface of the water, should at once be removed, or they will soon form dense masses, detrimental to the growth of the other occupants. If the Water Lilies are well furnished with foliage, the algæ would be less troublesome to deal with, and the introduction of a stock of fish would also prove very serviceable in keeping the same in check.

For the removal of dead leaves, weeds, or any accumulation of floating refuse, as well as to give the necessary attention to any plants requiring it in tanks

Aquatic Plants—*continued.*

visits, by destroying the buds and flowers of Water Lilies, but they may generally be captured without very much difficulty by means of tempting baits. Waterfowl might play havoc with small plants if unguarded, but it is most desirable that these should be grown in reserved quarters until sufficiently strong to plant out.

In selecting a site for an artificial piece of water it should be borne in mind that water naturally seeks its bed in low-lying ground; therefore, in the construction of a pond, it is very important that this particular should be observed wherever the conditions are favourable for doing so, or an unreal effect will otherwise be produced. The outline should be carefully considered, and circular or unnatural shapes should be avoided, as these would, to a cultivated taste, present a too artificial appearance. The sides should be represented by projections and

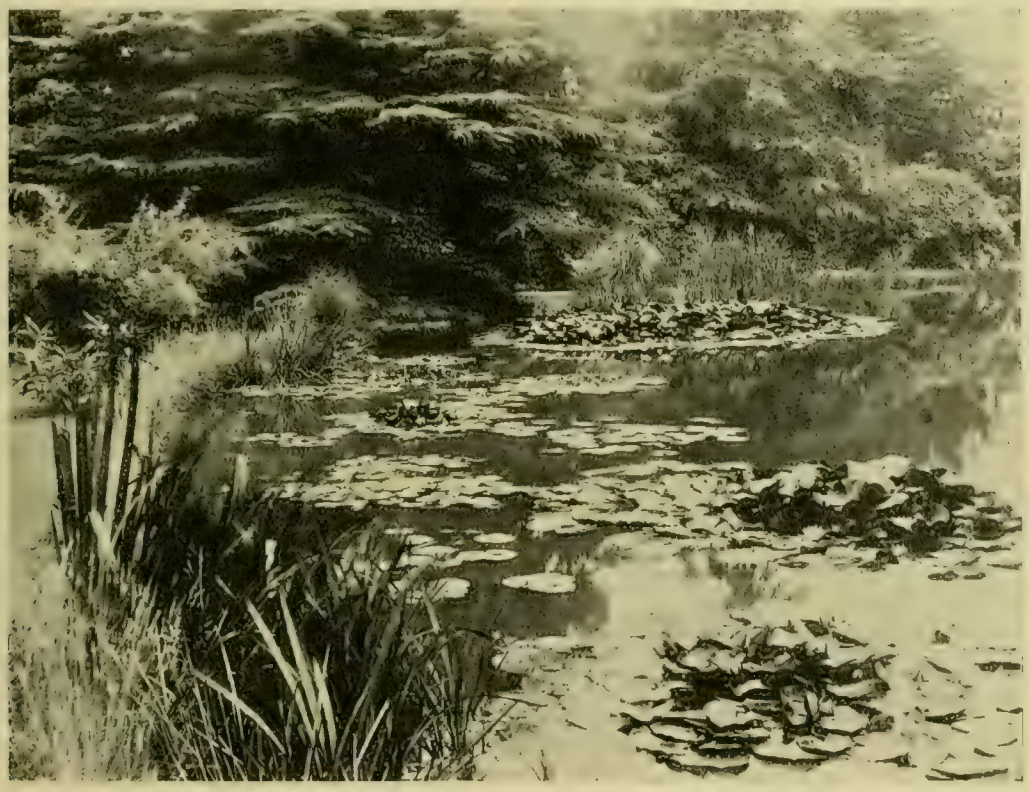

FIG. 70. HYBRID WATER LILIES AT GUNNERSBURY HOUSE, ACTON.

or small areas of water, a strong, light plank or ladder might be used of sufficient length to take a secure bearing at the ends; but in large ponds, where this is impracticable, wading-boots have to be resorted to.

Aquatics, more especially those with floating leaves, are fairly free from injurious attacks of insect pests, although sometimes they become affected with green and black Aphis. These can, however, generally be removed with the aid of a syringe or hose-spray; but the most effectual remedy is a natural one—a good heavy shower of rain, which also imparts to the plants an additional brightness. In some cases it may be desirable to use an insecticide, and should this be resorted to a solution of tobacco-juice will be found to answer the purpose effectually, without causing the least injury to the plants. Water-voles will sometimes become troublesome, if allowed to be undisturbed in their

irregular curves, avoiding the introduction of straight lines, which are invariably objectionable, and seldom occur in a natural formation. Artificial work, as far as possible, should be carefully concealed below the intended water-level line, or provision made for concealing it with vegetation when planting operations are in progress. If the soil is of a clayey nature and retentive of water where it is designed to form a pond, this work will be very much simplified; but should it be of a porous nature, then tempered clay will have to be introduced and puddling resorted to in order to prevent waste of water when the work is completed. When the soil has been excavated as deeply as may be desired—say to a minimum depth of about 3½ft. in the middle or deepest part, gradually diminishing to about 1½ft. at the margin, the sides sloping outwardly—the surface of the

Aquatic Plants—*continued.*

excavation should be made as firm as possible, and regularly finished off, ready for the puddling operation. To effect this, clay should be beaten and worked into a thoroughly tenacious mass wherever most convenient to do so, and when it is fit for use the bottom and sides of the pond should be evenly covered throughout with it to a thickness of 9in. to 12in. This will require to be well rammed and beaten as the work proceeds, so that it may be thoroughly united, and so prevent the water from percolating through it. This work should be done expeditiously, and as soon as it is completed the water should be gradually admitted. Of course, cement concrete might be used for lining the interiors of small ponds, but in the case of larger ones this would be a rather expensive process in comparison with puddling with clay. After the puddling operation is completed, the deepest part in the pond would be from 2½ft. to 3ft., and this would form the most suitable position for depositing the necessary mounds of soil for the reception of Nuphars and the more vigorous-growing Nymphæas that may be selected, the margin being suited to the requirements of those plants that only require shallow water in which to grow.

In supplying an artificial pond with water, it is very important that the source from which it is obtained should be considered, as Aquatics, and more especially the choicer kinds of hardy Nymphæas, do not flourish satisfactorily in continually running water of a low temperature, as by a continuous current of cold water entering the pond, and this observation applies particularly to the *odorata* group. Therefore, for the benefit of the plants, every provision possible should be made to ensure as high and as constant a temperature as possible, more especially during the time that the plants are in active growth. A pond situated in a sheltered, sunny position provides the best aspect, especially so for those of tender habit, and it would conduce to a greater prolongation of their flowering period. Where a sufficient, constant, and steady supply can be laid on from an extraneous lake, river, or stream, it will be of great advantage to do so, this being more beneficial to the health of the plants than that supplied direct from a natural spring or drawn from a low-level in the earth. The water obtained from the last-named sources is of too chilly a nature to favour a luxuriant growth, whereas the former would obviously best meet the plants' requirements, it being aërated and, consequently, of a higher temperature. The inrush of any considerable quantity of water should also be avoided, as the disturbance caused thereby is calculated to be detrimental to their well doing. All that is really required is a sufficient supply of water to prevent stagnation, and, when this is well regulated, successful culture will be in a great measure assured. Means should also be taken to prevent the level of the water from fluctuating to any appreciable extent by constructing an outlet at the intended water-level line, which will suffice for carrying off a similar quantity of water to that which enters the pond.

Where an opportunity is afforded of forming a small pond in connection with a well-made rockery, provided one does not already exist, if properly constructed and judiciously planted, it will form an additional charm to that always interesting and attractive feature in a garden. In its formation an irregular outline should be observed, as this would be conducive to its presenting a natural, and therefore more pleasing, appearance when completed.

In gardens of limited space brick, stone, or concrete tanks about 2½ft. in depth might be constructed, and these, if built entirely in the ground with the walls gradually sloping outwardly at the top, would minimise the risk of their being damaged during a long spell of severe frosty weather. A sunny position should be selected, and the site and formation of a tank of this description should be carefully considered in connection with the surroundings. In its construction a natural effect should be aimed

Aquatic Plants—*continued.*

at as much as possible, so that it will not present a too formal appearance.

A supply of water might be laid on by means of pipes, to which a valve should be fitted, so that the volume of water entering the tank may be regulated. The higher the mean temperature at which the water can be maintained in the tank, the more generally beneficial will it be for the plants. Only sufficient fresh water need be allowed to enter to prevent stagnation. An efficient outlet is also a necessity, and this should be situated at the intended water-level line to prevent any appreciable fluctuation. In favour of tanks it may be urged, without in any way depreciating the value of ponds, that they afford better facilities for more closely viewing the beauty of the Water Lilies than is the case when the plants are situated in large pieces of water.

Ordinary tanks or fountain-basins, where they already exist, if of sufficient depth and dimensions, would be available, although their stiff, artificial appearance makes them less pleasing to the eye in comparison with those which are designed on more natural lines. In the case of fountain-basins choice plants should not be allowed to occupy positions where sprays of water would be continually falling upon them when the fountain is playing.

In a naturally-formed piece of water where a deposit of several inches of mud has accumulated, very little difficulty will be occasioned in establishing the plants if due care be taken to make their roots secure. But should the bottom be of a gravelly nature, or otherwise unsuitable to their requirements, then mounds of soil, consisting of good, rich, heavy loam of a tenacious nature, with about one-third of well-decomposed cow- or stable-manure, to which a little leaf-soil might be added, although it is not absolutely necessary, and the whole thoroughly incorporated, should be deposited for their reception. This also applies to the planting of artificial ponds, unless it be intended to grow the plants in submerged tubs or boxes—a plan, however, which, in the case of a pond of any large extent, cannot be recommended as being more satisfactory than that of planting them out on mounds.

Where it is inconvenient or undesirable to lower the depth of the water sufficiently to allow of the planting of Aquatics directly into the mud, or mounds of soil, in which they are to grow, a good method is to plant them firmly in similar soil to that recommended above, in baskets about 2½ft. in diameter and from 6in. to 9in. deep—what are known as small nursery rounds would answer the purpose. This operation should be performed as expeditiously as possible, afterwards lowering the baskets from a punt or raft into the positions the plants are to occupy, whether on the bed or on the mounds of soil, as the case may be. When the baskets become decayed, or even before, the roots will be found to have penetrated through, and have taken possession of the mud or soil below, attended with a corresponding vigorous growth of the entire plant. In the case of Nymphæas, only strong, healthy plants should be submitted to this treatment. Small plants should be nursed in shallower water, or where they would be under close observation, until sufficiently strong to be transferred to deeper quarters. In the case of small plants it is advisable to remove the flower-buds as they appear. The compost recommended to be used for planting in the above instance would be that which would also be found to meet the requirements of those grown in all circumstances where beds, tubs, or boxes are used for their reception, provided a minimum depth of 9in. of same be allowed for them to develop as much root growth as possible. This compost would also serve for the purpose of renovating the surface whenever necessary, and this operation is invariably attended with good results if done before each season's growth commences.

Where sufficient space exists for the inclusion of a representative collection of the most ornamental Aquatics, a water-garden may be made all the more attractive by a

Aquatic Plants—*continued.*

judicious disposition of the plants according to their individual characteristics, more particularly with respect to their habit of growth. For instance, there are those kinds whose leaves float on the surface of the water, amongst which are included the beautiful Water Lilies and the Sweet-scented Water Hawthorn; whereas other kinds assume a more or less tall and erect habit, as, for instance, the Flowering Rush and the Bog Bean. Then there are those the foliage of which is entirely submerged, but which produce their flower-scapes above the surface of the water, such as the pretty Water Violet, the Water Soldier (*Stratiotes aloides*), and the interesting Bladderworts, besides numerous other equally desirable and pretty subjects that thrive luxuriantly at the water's edge, where their roots can revel in an abundance of moisture.

The most suitable time for planting hardy Aquatics is about the beginning of April, or as soon as they commence active growth. Of course it may be desirable afterwards to introduce a few new acquisitions, to fill up spaces where plants may have failed, or to introduce a few tender kinds during the summer months which require the protection of a greenhouse during the winter; but for general planting, the time stated above is invariably the most advantageous. In ponds, the groups—more especially those with floating leaves—should be separated from each other by clear open spaces of water, so that when in full growth their beauty will be better displayed, and the surface will not present the appearance of being too much covered with foliage, which would have a decidedly monotonous effect.

So much for the hardy section. Now for the tropical and tender plants. Everyone who has viewed a representative collection of tropical and tender Aquatic Plants must have admired the great diversity of their appearance and, in many instances, the contrasts they present to the more familiar ones of temperate or northerly latitudes. Forming, as they do, a class of plants requiring conditions resembling, as nearly as possible, those in which they are found thriving in their native habitats, their cultivation in this country has necessarily been limited to some of the principal establishments where these conditions have been afforded, and they then have gained for their enterprising owners the genuine appreciation of horticulturists.

In the construction of a house for the cultivation of tropical Nymphæas and other Aquatics, the span-roofed form is the most suitable to adopt, as this admits the greatest amount of light, which is a most essential condition in their successful cultivation. The roof should not be too lofty—this is also an important point in connection with the conditions to be observed in their treatment. As no shading will be required it is all the more necessary that the house should be glazed with good clear glass, as oftentimes, through the presence of air-bubbles in the glass, which focus the sun's rays, heat is conducted which scorches holes in the leaves, and thereby disfigures the plants. Ventilation should be amply provided, both in the sides of the house and in the roof, for Aquatics generally, and Nymphæas in particular, when in full growth, require abundance of air on hot, sunny days. Around the inside of the house, abutting on the walls, benches or borders may be formed for the accommodation of ornamental plants, or small tanks or beds may be constructed for the culture of Aquatics, or moisture-loving plants. For heating the house, sufficient pipes should be introduced to ensure a minimum temperature of from 65deg. to 70deg. Fahr., and this would afford means for maintaining a higher temperature when desired, and would minimise the amount of piping necessary to be employed for heating the tank.

A tank for the reception of the Aquatics should be constructed in the centre of the house, and whatever the desired shape may be, and whether entirely sunk in the ground, or partly above the ground-level, a firm foundation must be first secured. The bottom should be made perfectly

Aquatic Plants—*continued.*

solid with a layer of bricks well bedded in cement and sand, and on the top of this course a good thickness of stone or brick rubble concrete should be added. The walls may be built with either brick, concrete, or stone, the thickness of which will largely depend upon the size of the tank. If it be desired to have a tank from 20ft. to 30ft. in diameter and about 2ft. 6in. in depth, walls 12in. thick to within 10in. of the top, and from that point sloping outwardly, with the masonry set in cement, would be sufficiently strong. The tank should afterwards be faced both inside and out with about 1in. coating of good cement, and the surface smoothly finished off to make it watertight. On the inside, formed against the walls, a few beds, enclosed in brickwork, might be introduced for the accommodation of strong, erect-growing Aquatics; these should reach to about 6in. below the top of the tank, so as to admit of their being submerged to a depth of 3in. or 4in. when the water is at its normal height.

For heating a tank of the dimensions given, two 4in. pipes (a flow and return) carried round the inside, about 6in. from the walls and the same distance from the bottom, will be quite sufficient, and these should be furnished with valves on the outside of the tank to allow of regulating the temperature of the water. An air-pipe should be fitted to the flow-pipe at its highest point, to release any air or steam that may accumulate in the pipes. The tank should be furnished with a plentiful supply of water, and a tap connected with the service-pipe, so that it can be turned on to its full capacity when the tank requires refilling, or regulated to a gentle flow when the Aquatics are in full growth, or as desired. An overflow stand-pipe is also necessary, the top of which should reach to nearly the full height of the tank. If constructed in two parts, somewhat on the telescope principle, so that the upper portion can be raised or lowered by sliding or screwing into the bottom part, means will thus be afforded for keeping the water at any desired height. A large brass perforated cap, similar to the rose of a watering-can, should be fitted to the top of the overflow-pipe to prevent floating matter from choking it, and the escape of small Aquatics. This stand-pipe should be situated conveniently close to the wall. It should be fitted into another pipe, set level with the bottom of the tank and connected with the drain provided, so that when any operations necessitate the tank being emptied the stand-pipe can be removed and the water readily drained off. If it should be considered desirable to paint any part of the tank that is above the ground-level, it will be best to defer doing so for a time, as the new cement would blister the paint and cause it to peel off.

It is not advisable to plant a new tank immediately after it is finished, but it may be filled with water, which should be allowed to stand for at least a week. The scum that will have by this time accumulated on the surface should be flushed and syringed off, and the tank then filled up with fresh water.

The next important operations are the arrangement of the tubs or large pots in the tank, and the preparation of the soil in which the Aquatics are to be planted. Of course, brick enclosed beds may be more freely introduced where plenty of room is afforded for growing very large specimens; but in a tank of limited dimensions, where it is desired to grow several plants of moderate size, tubs or large pots will be the most suitable, as these have the advantage of being readily moved. If tubs are employed—and perhaps they are preferable for an indoor tank—a very useful size will be found in those measuring about 18in. square, and the same in depth, with the angles securely dovetailed. They are best made of well-seasoned 1in. elm boards, as this wood is very durable when submerged in water.

The *Nymphæa* family is represented by so many species and varieties of decided merit that they should occupy a

Aquatic Plants—*continued.*

great portion of the tank (Figs. 71 and 72); therefore, it will be best to treat upon their culture first. From their habit of growth it is necessary that they should occupy the central part of the tank, the tubs or pots when in position being about 5ft. apart, and arranged alternately, so as to utilise all available surface space for the foliage. For Nymphæas to display their greatest beauty, in respect of both size and colour of their flowers, when under artificial treatment, they must have a good rich compost; and, unless this is afforded them, it is only courting disappointment to attempt their cultivation.

A compost should be prepared consisting of good, rich, heavy loam, containing an admixture of clay, and to this

Aquatic Plants—*continued.*

When filling the tubs and planting, the soil should be pressed firmly down and around the plants or tubers to within 3in. of the top, which should be surfaced with about 1in. of sand to prevent (as far as possible) the manure in the soil from rising and discolouring the water. If the tubs or pots are too full, the action of the water causes the soil to swell and run over the sides; allowances must, therefore, be made for this. When the water in the tank is at its normal height, a depth of from 10in. to 12in. above the crown of the plants will be found sufficient.

As tropical Nymphæas may be definitely classed in two divisions—namely, those displaying their flowers by day, and others that do so by night—the best effect will be

FIG. 71. VIEW OF LILY TANK IN THE OXFORD BOTANIC GARDEN

should be added a good proportion of well-decomposed cow- or stable-manure as well as a small quantity of leaf-soil, but the last-named is not absolutely necessary. If it is convenient to procure the loam from an old pasture, the top spit should be selected, and this should be stacked for about twelve months; it will then be in excellent condition. When preparing the compost the loam should be chopped up fairly coarse, and to every three parts of this should be added one part of cow- or horse-manure—the former for preference. This, when well incorporated, will form a compost of a tenacious nature, suited to the wants of the plants. The soil should be placed in the house for a few days previous to its being required, so that it may get moderately warmed.

secured if they are planted alternately, so as to have them equally distributed over the tank, with due regard to the arrangement of their colours. The *Lotus* and the *stellata* sections form two distinct groups of Water Lilies, the former embracing colours ranging from white to deep red, and the latter from pale to deep blue. As soon as the boxes are planted, the tank should be filled with water. By turning the heat fully on in the hot-water pipes, the water will be warmed as it gradually rises. This will not in any way interfere with the planting at the sides, as the plants situated there, excepting the floating ones, will be in beds or in pots resting on shelves or brick columns, provided for those which require only a shallow depth of water above the surface of the soil. Tall and vigorous-growing

Aquatic Plants—*continued.*

Aquatics, such as *Cyperus Papyrus*, *Thalia dealbata*, and *Sagittaria montevidensis*, should be planted in beds, to form good bold clumps, and any old or superfluous growth cut away before planting; this should be done firmly, leaving the crowns just above the top of the soil. The smaller-growing kinds may be accommodated in pots at the sides, with the surface of the soil just submerged.

Nelumbiums, which form such an important feature in an Aquatic-house, with their large, orbicular-peltate leaves and massive flowers—yellow, white, and various shades of rose—require very liberal treatment at the roots, and plenty of space for their long, fleshy rhizomes to develop in. When preparing a bed for their reception, the soil should consist of rich, heavy loam (as previously recommended for Nymphæas), two parts to one of good decomposed cow- or horse- manure well incorporated. The soil should be firmly pressed down, planting the rhizomes horizontally, and covering them to a depth of about 6in. Nelumbiums are very impatient of root-disturbance, therefore they should seldom be interfered with, even when they are well established, beyond giving them an annual surfacing of good rich soil. They may be successfully grown in tubs or large pots, but the best results are obtained when space admits of their being treated in the manner described above.

Floating Aquatics, or those kinds that do not necessarily require soil in which to grow, form especial objects of beauty when established in small colonies at the sides of the tank, and these include the Water Lettuce (*Pistia Stratiotes*), a pretty rosette-like plant with pale green leaves; *Limnobium bogotense*, which has little, round, deep green, shining leaves; and the elegant little fern-like annual, *Salvinia natans*, which reproduces itself from spores.

The most suitable time for planting Nymphæas in an indoor tank is from the middle to the end of February, and this also applies to the majority of tender Aquatics. Of course, the occasional introduction of additional plants will occur during the growing season—it may be of annuals or plants which are best treated as such—and these may be included at any time, as they will in no way interfere with the general planting and arrangement of the tank for the year. When this has all been done, the temperature of the water in the tank should be kept at about 70deg. Fahr., with a gradual rise as the summer advances: it should then not be allowed to exceed 80deg., but this should be maintained as uniformly as possible during the summer months.

FIG. 72. WATER LILY HOUSE AT KEW.

The house should be freely ventilated on bright sunny days, and the paths and sides occasionally damped down to prevent the atmosphere from becoming too dry, closing the ventilators in the afternoon while the sun is still on the house, and at the same time giving the plants a good syringing and the paths and sides a thorough damping down. Should green or black Aphis affect them, fumigation, which is very effectual, should be resorted to; but before this is done the surface of the foliage should be quite dry, or it will become disfigured. As the season draws to a close, the temperature of the water in the tank should be gradually diminished to about 60deg. Fahr., and this should be maintained throughout the winter months.

When the season for replanting comes round, before operations are commenced it will be advisable to run all the water out of the tank, as this will greatly facilitate

Aquatic Plants—*continued.*

the planting, and no fear need be apprehended that the plants to be re-introduced will come to any harm providing care is taken in removing them, as practically they will be at rest and without much foliage. It will also be obvious that the more expeditiously the work can be accomplished, consistently with proper care, the more satisfactory will be the results. With few exceptions the Nymphæas will then be quite devoid of foliage, and especial care should be taken when emptying the tubs of soil so as not to overlook any of the tubers. Some sorts increase very slowly, but the *Lotus* section are quite the reverse, being vigorous growers, and proportionately productive of tubers. Should any of these by chance get into a tub of another sort of weaker habit they will soon establish themselves and take entire possession. The tubers, when removed from the tubs, should be placed in pots of damp moss, and each sort labelled to prevent any confusion arising when replanting is in progress. Tubs or large pans filled with water should be conveniently to hand for the accommodation of the floating plants, and wet moss will be found very useful for covering the roots of others when removed from the tank.

The tubers of Water Lilies during their resting period are best left in the tubs in which they have been growing; but if it is necessary to remove them they can be safely kept in wet soil or sand in a warm house; and those sorts that do not die down entirely should be placed in pots of soil, submerged in pans of water, and placed in a similar position.

Aquatics may be raised from seeds at any time during the growing season, but the best results are obtained if the sowing is done early in the spring, excepting in the case of the Royal Water Lily (*Victoria regia*) and *Euryale ferox*. Seedling tropical Aquatics may be raised in an ordinary plant-stove if the temperature of the water can be maintained at about 75deg. Fahr. A simple and easy method to adopt is to sow the seeds in small pots or pans, about two-thirds filled with fine loamy soil, which should be firmly pressed down, and the seeds lightly covered. They should then receive a thorough soaking of water, and be allowed to stand for a short time before being submerged in jars or vessels of water, allowing about 2in. depth of water to cover the tops of the pots. Of course, tanks or cisterns, in which the water is of a suitable temperature, may be used; but if the water is constantly disturbed by some of it being taken out, it will have an injurious effect on seedling plants, and there will be the risk of seeds being washed out of the pots. Care should also be taken not to entirely fill the pots with soil, or the action of the water will cause it to swell and float over the sides, as stated above, which would probably result in the loss of the seeds. The seeds of many of the Nymphæas germinate quickly, and if sown early in the spring and the seedlings are pricked off as soon as they are large enough to handle, afterwards transferred singly into pots filled with good, rich soil, and the depth of water above their crowns increased as the plants develop, they should form flowering plants before the season is over. This remark particularly applies to the *stellata* group, the seeds of which germinate in about a fortnight, and, as the roots of the majority of them increase very slowly, this is the quickest and best method of propagation. The seeds of the *Lotus* section require about double the time to germinate, and, unless it is with a view to raising new sorts, they are scarcely worth the trouble, as they all, as previously stated, increase rapidly by means of tubers. Nelumbiums are easily raised from seeds, the germination of which can be greatly facilitated by carefully rubbing one side of the hard outer covering of the seeds with a file till thin, after which process they will germinate in a few days: otherwise they will require several weeks. Nelumbiums will also germinate in water placed in a warm house, but this is not a better method than the preceding. The seeds retain their vitality for a great length of time, owing to the extreme hardness of the outer covering.

Aquatic Plants—*continued.*

If it is desired to grow a plant of the Royal Water Lily, *Victoria regia* (Fig. 73), with other Aquatics in a tank, as previously described, this will necessarily require the central part of the tank. In this case a pit should be formed in the centre about 18in. in depth and large enough to contain from three to four cart-loads of soil; otherwise there would not be a sufficient depth of water above the crown of the plant. Where a tank is constructed especially for the cultivation of this Giant Lily of the Amazon—and it well merits such accommodation—it may be treated as an annual, and will then only occupy the tank from the spring till the autumn. The place may then be cleared out and utilised for the reception of large specimen plants, either arranged in the tank or on a temporarily-constructed staging of planks, supported at the sides and in the centre by trestles or brick columns. It will also serve to accommodate tender plants removed from their summer quarters out of doors, and thus be rendered attractive throughout the winter months.

To cultivate the Victoria satisfactorily it requires very liberal treatment at the roots, a large tank in which to grow, and the temperature of the water to be kept at from 80deg. to 85deg. during the summer months. The seeds, which usually take from eighteen to twenty days to germinate, should be sown about the end of January in a pan of soil, and submerged in water of the temperature already given. As soon as the seedlings are large enough to handle, they should be transferred singly into small pots, and when necessary shifted into larger ones containing good, rich soil. The pots should be so submerged that the crowns of the plants are only a few inches below the surface of the water, increasing the depth as the plants get stronger.

The number of plants available for growing either in the water or at the sides of it is very great. All, therefore, that is possible is to refer to what may be termed a select few in each section—Hardy and Tender.

First, as to those of the Hardy section, with floating and submerged leaves, of which the beautiful white Water Lilies of our rivers are such familar examples. Here we have *Alisma Plantago*, *Aponogeton distachyon*, *Hottonia palustris*, *Hydrocharis Morsus-ranæ*, *Hydrocleys Commersoni*, *Limnanthemum peltatum*, *Nuphar advena*, *N. lutea*, *N. pumila*, *Nymphæa alba*, *N. a. candidissima*, *N. odorata*, *N. pygmæa*, and *N. tuberosa*.

Then besides the species and varieties of Nymphæas are a host of hybrids, for which we are largely indebted to M. Robert Latour Marliac, and of which the following are the best:

ANDREANA, flowers brick-red, shaded with yellow, cup-shaped, and borne on long stems bearing the flowers 6in. above the water, stamens deep orange; leaves spotted with red-brown on the back and chestnut on the stalks. AURORA, flowers opening clear yellow, changing in a few days to brilliant red; leaves deep brown, streaked with a brighter shade at the back; a beautiful variety. CAROLINIANA NIVEA, flowers waxy white, of excellent form and great size, stamens deep yellow; exquisitely perfumed. CAROLINIANA PERFECTA, flowers salmon-red, very double, petals obtuse and regular, stamens deep clear yellow. ELLISIANA, flowers bright clear red, stamens a deep orange red; a charming variety. FULVA, flowers bright red, shaded with purplish-red, which becomes intensified with the age of the flower; petals incurved, stamens orange-red. GLORIOSA, flowers bright red, shaded with pale rose at the points of the petals, stamens rich red, very large and double, usually 7in. across, and sweetly scented; a superb variety. LAYDEKERI FULGENS, flowers rich amaranth, stamens deep red; a splendid variety that will become popular. LAYDEKERI LILACEA, flowers soft lilac, shaded with carmine at the points of the petals, stamens deep apricot; a very pretty variety, throwing its flowers well above the water. LAYDEKERI PURPURATA, flowers soft pink, deepening to crimson at the centre, stamens apricot. LAYDEKERI ROSEA, flowers soft pink, deepening in colour with age. LUCIDA, flowers bright pink, deepening towards the centre, very large and handsome, stamens rich orange; leaves large and marked with brown. MARLIACEA ALBIDA, flowers pure white, stamens soft yellow, large, 8in. across; very robust. MARLIACEA CARNEA, flowers soft pink, stamens soft yellow, sweetly scented, very large; a vigorous growing variety. MARLIACEA CHROMATELLA, flowers canary-yellow, stamens a little paler, very large; leaves

Aquatic Plants—*continued.*

marked with brown; vigorous and very handsome. MARLIACEA FLAMMEA, flowers dull red, shaded lightly with white at the points of the petals, stamens deep red; in growth and foliage similar to *M. chromatella*. MARLIACEA IGNEA, flowers dull or purplish red, stamens deep apricot. MARLIACEA ROSEA, an improved form of *M. carnea*. MARLIACEA RUBRA PUNCTATA, flowers pale red, deepening towards the points of the petals, stamens rich apricot; a lovely new hybrid. ODORATA EXQUISITA, flowers deep pink, stamens bright yellow, very sweetly scented; the flowers are of perfect form, and well thrown above the water; a really charming kind. ODORATA ROSACEA, flowers delicate pale pink, stamens clear yellow, sweetly scented; a free, vigorous growing hybrid. ODORATA SULPHUREA, flowers sulphur-yellow, stamens a deeper shade, standing 6in. above the water; leaves spotted with light brown. ODORATA SULPHUREA GRANDIFLORA, a glorified form of *O. sulphurea*. PYGMÆA HELVEOLA, flowers soft yellow, with stamens of a deeper shade, small, abundant, and very attractive; this plant succeeds very well in small vessels, or tubs sunk in the ground. ROBINSONI, flowers vermilion, shaded with deep purple, changing to yellow at the centre, stamens deep apricot; a lovely hybrid. SANGUINEA, flowers a beautiful shade of red, stamens orange-red; very attractive. SEIGNOURETI, flowers a charming blending of yellow, pink, and red, and seen to great advantage, as they are usually 6in. to 8in. above the water.

There are several introductions from other sources, chiefly from America and Sweden, one of the most distinct being *N. alba rosea* (*N. Caspary*).

Other species falling under the heading above adopted are *Orontium aquaticum*, *Stratiotes aloides*, *Trapa natans*, and *Utricularia vulgaris*. Some of those selected will be recognised as familiar British plants, but none the less desirable on that account.

Of the erect-growing hardy Aquatics and Sub-Aquatics there are, amongst others: *Acorus Calamus*, *A. C. striata*, *A. gramineus*; *Alisma Plantago*; *Butomus umbellatus*; *Calla palustris*; *Cladium germanicum*, *Iris Pseudacorus*, and *I. P. variegatus*; *Lysimachia thyrsiflora*; *Menyanthes trifoliata*; *Peltandra virginica*; *Phragmites communis*; *Pontederia cordata*; *Ranunculus Lingua*; *Richardia africana*; *Sagittaria sagittæfolia*; *Scirpus lacustris*; *Typha angustifolia*, *T. latifolia*, *T. Laxmanni*, and *T. stenophylla*.

Aquatic Plants—*continued.*

Waterside Plants should also be adequately represented, some very effective subjects being: *Acanthus mollis*, *A. m. latifolius*, and *A. spinosissimus*; *Arundo Donax* and *A. D. versicolor*; Bamboos; *Cyperus longus*; *Equisetum sylvaticum* and *E. Telmateia*; *Erianthus Ravennæ*; *Funkia Sieboldiana*, *F. ovata*, and *F. o. marginata*; *Gynerium argenteum*; *Gunnera chilensis* and *G. manicata*; *Juncus effusus spiralis*; *Miscanthus japonicus* and its varieties *foliis-striatus* and *zebrinus*; *Onoclea germanica* and *O. sensibilis*; *Osmunda regalis* and *O. r. cristata*; *Panicum virgatum*; *Phalaris arundinacea variegata*; *Podophyllum Emodi* and *P. peltatum*; *Polygonum sachalinense* and *P. s. cuspidatum*; *Rheum Emodi* and *R. palmatum*; *Rodgersia podophylla*; *Scirpus Holoschænus variegatus* and *S. Tabernæmontani zebrinus*; *Scolopendrium vulgare*; and *Uniola latifolia*.

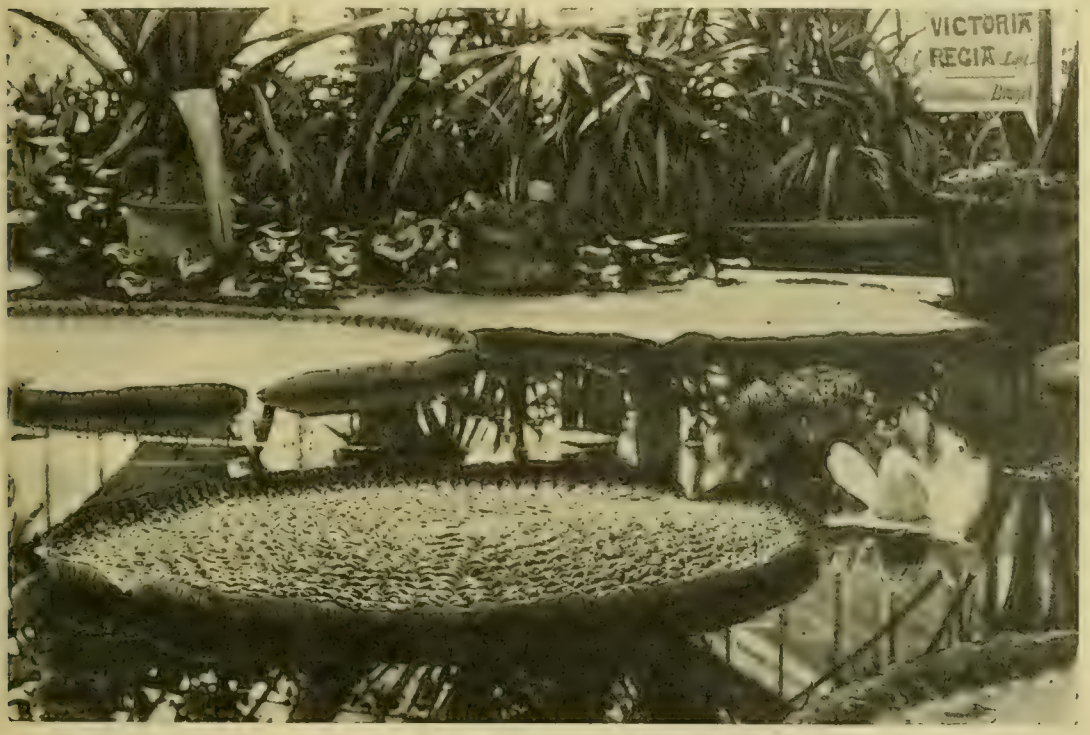

FIG. 73. VICTORIA REGIA AT KEW.

Flowering Waterside Plants offer an even wider choice for the enthusiast in Aquatics, and those mentioned hereunder may be recommended: *Asclepias incarnata*, *Astilbe rivularis*; *Bocconia cordata*; *Caltha palustris* and *C. p. monstrosa*; *Cardamine pinnata* and *C. pentaphylla*; *Epilobium angustifolium*, *E. a. album*, and *E. hirsutum*; *Hemerocallis flava* and *H. fulva*; *Iris lævigata*, *I. Monnieri*, and *I. sibirica*; *Kniphofias*; *Lilium pardalinum*, *L. superbum*, and *L. s. carolinianum*; *Lysimachia clethroides* and *L. c. vulgaris*; *Lythrium Salicaria* and the varieties *roseum* and *superbum*; *Myosotis palustris*; *Parnassia palustris*; *Polygonatum multiflorum*; *Primula japonica* and *P. sikkimensis*; *Saxifraga peltata* and *S. purpurascens*; *Spiræa Aruncus*, *S. astilboides*, *S. camtschatica*, *S. lobata*, *S. palmata*, and *S. Ulmaria*; *Trillium grandiflorum*; *Trollius asiaticus* and *T. europæus*; and Yuccas.

Aquatic Plants—*continued.*

Tropical and tender kinds embrace the following amongst others: *Aponogeton fenestrale; Cabomba aquatica; Ceratopteris thalictroides; Cyperus alternifolius, C. a. variegatus, C. natalensis,* and *C. Papyrus; Eichhornia azurea, E. Martiana,* and *E. speciosa; Herpestis Monniera; Hydrolea spinosa; Jussieua grandiflora; Limnanthemum indicum; Limnobium bogotense; Limnocharis emarginata; Myriophyllum proserpinacoides; Nelumbium luteum* and *N. speciosum; Neptunia plena; Nymphæa amazonum, N. Boucheana, N. capensis, N. Daubenyana, N. Deaniana, N. devoniensis, N. elegans, N. Eugenie, N. flava, N. gigantea, N. gracilis, N. kewensis, N. Lotus, N. L. dentata, N. L. monstrosa, N. L. rubra, N. L. thermalis, N. mexicana, N. micrantha, N. O'Marana, N. Ortgiesiana, N. pulcherrima, N. stellata, N. s. cyanea, N. s. versicolor, N. Sturtevantii, N. zanzibarensis,* and *N. z. azurea; Ottelia ovalifolia; Philydrum lanuginosum; Pistia stratiotes; Sagittaria lancifolia, S. l. angustifolia,* and *S. montevidensis; Salvinia natans;* and *Thalia dealbata.* The last-named (*Thalia dealbata*) has been grown in ornamental water at Kew in the open air for many years; it is nearly hardy.

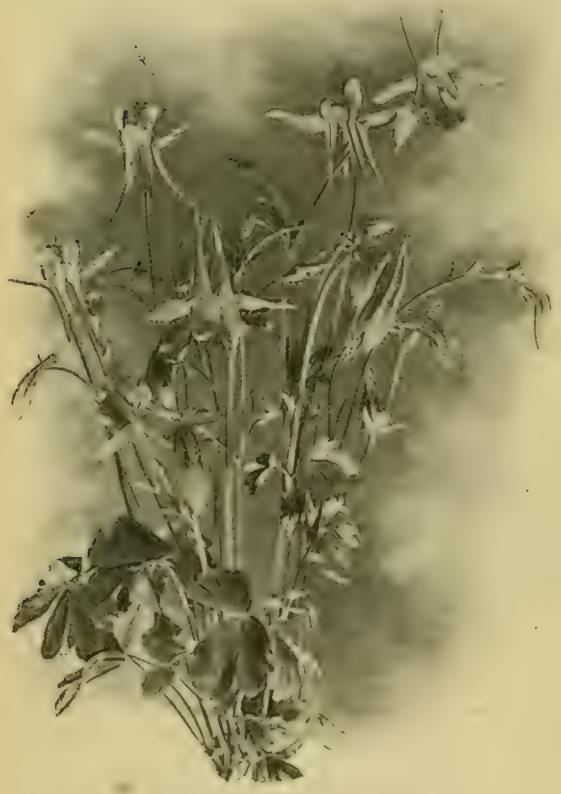

FIG. 74. AQUILEGIA CHRYSANTHA.

AQUILARIA (from *aquila*, an eagle; the native name in Morocco is Eagle Wood). SYNS. *Agallochum, Ophispermum.* ORD. *Thymelæaceæ.* A small genus (two or three species) of stove trees, natives of Eastern Asia and the Malayan Archipelago. Flowers pedicellate; umbellules sub-sessile, axillary or terminal. Leaves alternate. *A. malaccensis,* the only species introduced, is probably not now cultivated.

AQUILARIEÆ. A tribe of **Thymelæaceæ** (which *see*).

AQUILEGIA. According to Bentham and Hooker, the numerous species may be reduced to about five or six; they are mostly distributed over the North temperate zone, the genus being represented in Britain by *A. vulgaris.*

These useful plants have been very much employed of late years, and considerable improvements have been made by the florist. The beautiful hybrid forms, both long-spurred and short-spurred, are extremely decorative, and some of the best should always be included. Columbines are not as often used on the rockery as they might be, considering their utility. Usually these plants are regarded as pure sun-lovers, but as a matter of fact shade is good for them, and especially for those early kinds which push their buds while frosts are to be reckoned with. To grow, for instance, the lovely hybrid *A. Stuarti* in a south border, or in any position where the sun strikes very early in the morning, is to sacrifice much of its beauty. A north-west border is the best place for this, as in the event of spring frosts the thawing process would be gradual; whereas if strong sun immediately followed a severe frost the buds would be for a certainty damaged. And similarly with other early-flowering kinds. Those who study effect in their gardens will find it best to raise a fresh stock of Columbines each year, instead of, as is frequently done, retaining the old plants. For the rock garden *A. alpina, A. cærulea, A. pyrenaica,* and *A. glandulosa* are the best kinds; they may also be utilised for border decoration, so long as the soil is rich, moist, deep, and free, along with *A. canadensis, A. formosa, A. chrysantha* (Fig. 74), *A. Skinneri, A. Stuarti, A. vulgaris* and its white form *alba*, and the beautiful Munstead White, a tall-growing (2ft.) large-flowered variety.

To the species and varieties described on pp. 100-2, Vol. I., the following should be added:

A. atrata (dark). A variety of *A. vulgaris.*

A. cærulea flore-pleno (double-flowered). An apparently double-flowered variety; a number of the stamens are transformed into white, petaloid processes, tubular at the base. 1880.

A. cæruleo-chrysantha (hybrid). A garden hybrid between the two species indicated in the name. 1889.

A. chrysantha nana (dwarf).* *fl.* golden-yellow. *h.* 1½ft. 1890. A pretty variety.

A. flabellata (fan-shaped). *fl.* white, slightly tinted with violet-rose. A very early-flowering, compact-habited, dwarf, garden form. (R. H. 1887, p. 548.) The variety *flore-alb o* has flowers entirely white.

A. f. nana flore-albo (dwarf, white-flowered). A garden variety. 1888.

A. hybrida (hybrid). A form of *A. cærulea.*

A. kanaoriensis (Kanaor). A synonym of *A. Moorcroftiana.*

A. longissima (very long). *fl.* pale yellow, straw-coloured, nearly white, or tinged with red; spurs 4in. or more in length. *l.* glaucous beneath. Texas and Mexico, 1888. A handsome Columbine, of tall habit, slightly pubescent with silky hairs; it is allied to *A. chrysantha.* (G. & F. 1888, i., p.31, f. 6.)

A. Moorcroftiana (Moorcroft's). *fl.* purplish-blue, drooping, the petals white at the tips, resembling *A. vulgaris,* but all the spurs are straight. May and June. *l.*, radical ones on long stalks, bi-triternate; leaflets petiolulate, cuneate, three-lobed; cauline leaves remote, on shorter and less divided petioles. *h.* 1ft. Kanaor, Himalayas. SYN. *A. kanaoriensis* (B. M. 4693).

FIG. 75. FLOWERS AND LEAVES OF AQUILEGIA STUARTI.

Aquilegia—*continued.*

A. olympica flore-pleno (double-flowered). *fl.* blue, with a white centre, very large. 1888.

A. oxypetala (sharp-petaled). A synonym of *A. oxysepala.*

A. oxysepala (sharp-sepaled). This is closely allied to *A. vulgaris*, but has very narrow and very acute sepals and larger leaves. Siberia, 1890. SYN. *A. oxypetala.*

A. sibirica flore-pleno (double-flowered). *fl.* blue, large, very double; petals bordered with white, sometimes turning yellowish. There are other colour varieties.

A. Skinneri (Skinner's).* *fl.* drooping; petals with the limb yellowish-green and rounded, prolonged at base into a very long, tubular, lively red spur. Summer and autumn. *l.* mostly radical, glaucous, on long petioles, biternate; leaflets petiolulate and cordate, deeply three-lobed. Stem 2ft. to 3ft. high, panicled above. Guatemala. (B. M. 3919.) The variety *flore-pleno* (R. G. 1885, p. 57) has double flowers.

A. Stuarti (Stuart's).* *fl.* 3in. or more across, erect; sepals dark bluish-purple, 1¼in. long, large, regular; petals pure white, shading to bright blue at the base. 1894. A garden hybrid between *A. glandulosa* and *A. vulgaris Wittmanniana.* See Fig. 75.

A. transilvanica (Transylvanian). A synonym of *A. glandulosa.*

A. vulgaris atrata (dark). A form with dark violet flowers. 1890.

A. v. flore-pleno (double-flowered). *fl.* variously coloured and very double. The form *variegata* has lilac sepals and the limb of the petals white.

AQUILICIA. A synonym of **Leea** (which *see*).

ARABIS. Including *Stevenia* and *Turritis.* Upwards of 130 species have been referred to this genus, of which probably not more than sixty are entitled to rank as such; they are broadly dispersed, but most plentiful in Europe and North America. Six species are included in the British Flora, viz., *A. ciliata, A. hirsuta, A. perfoliata* (Tower Mustard), *A. petræa* (Northern Rock Cress), *A. stricta* (Bristol Rock Cress), and *A. Turrita* (Tower Cress, Tower Rockcress).

In very dry places the various kinds of Arabis are amongst the best of spring flowers. Used, too, in conjunction with the Alyssums they are very effective, especially as edging plants, where the variegated forms of *A. albida* and *A. procurrens* come in useful. These plants are not very compact of growth, and some little care is required to keep them neat-looking. This is best done by pegging down the stems. When employed for the decoration of the borders it is not unusual to plant them upon a mound.

To the plants described on p. 102, Vol. I., the following should be added:

A. alpina flore-pleno (double-flowered). An interesting garden variety with very double, white flowers. 1898.

A. muralis (wall-loving). *fl.* white; petals oblong; pedicels twice as long as the calyx; racemes erect, terminal. May. *l.* pubescent, toothed; radical ones spathulate, obtuse; cauline ones ovate, acute. Branches hairy. *h.* 4in. to 6in. Etruria, &c.

A. nudicaulis (naked-stemmed). A synonym of *Parrya nudicaulis.*

A. Stelleri (Steller's). *fl.* white; petals cuneate-oblong, twice as long as the calyx; raceme corymbose. June. *l.*, lower ones oblong-spathulate; upper ones half-amplexicaul, oblong, toothed. Kamtschatka. A capital little plant for the rock-garden.

A. Sturii (Stur's). An especially vigorous and compact garden variety, with large, pure white flowers. 1897.

ARACHNANTHE (from *arachne*, a spider, and *anthe*, a flower; in allusion to the shape of the flower). SYN. *Arachnis.* Including *Esmeralda.* ORD. *Orchideæ.* A genus comprising about half-a-dozen species of stove, epiphytal Orchids; one is Himalayan, and the rest inhabit the Malayan Archipelago. Flowers showy; sepals and petals free, spreading, rather thick; lip articulated at the base of the column, erect or spreading, neither saccate nor spurred at base, the lateral lobes erect or rarely obsolete, the middle one fleshy, polymorphous, often gibbous or with a very short spur at back; column short, thick; pollen masses two; peduncles lateral, elongated, simple or branched. Leaves distichous, fleshy-coriaceous,

Arachnanthe—*continued.*

sometimes very long, sometimes shorter or falcate, often obliquely bilobed at apex. Four species call for description here. For culture, *see* **Aërides.**

A. bella (pretty). *fl.*, sepals and petals light ochre, barred cinnamon, straight, cuneate-oblong; lip white, the lateral segments striped purplish-brown, the middle one very broad, tumid, the basilar, roundish callus white, spotted brown; raceme four-flowered. *l.* 5in. long, 1in. broad, shining, unequally bilobed at apex. 1888. SYN. *Esmeralda bella.*

A. Cathcarti (Cathcart's). The correct name of the plant described on p. 133, Vol. IV., as *Vanda Cathcarti.*

A. Clarkei (Clarke's). *fl.* much as in *A. Cathcarti;* sepals and petals dark brown, barred ochre, yellow inside, cuneate-oblong, obtuse; lip whitish, marked brown, three-lobed, with a conical, acute spur, the front lobe cordate, oblong-elliptic, with a rough, lobulate border, and seven to nine whitish keels; the mouth of the spur covered by two retrorse crests, with another crest in front. Himalayas, 1886. (B. M. 7077.) SYN. *Vanda Clarkei.*

A. Lowii (Low's). The correct name of the plant described on p. 283, Vol. III., as *Renanthera Lowii.* (R. 1889, 71.)

A. L. Rohdeniana (Rohden's). *fl.* brighter-coloured than in the type, the four lower yellow ones being separated from the rest by an interval of 9in. to 12in. *l.* narrower and shorter. Borneo, 1891.

A. moschifera (musk-bearing). *fl.* creamy-white or lemon-colour, spotted purple, large, resembling a spider, delicately scented like musk. Java. A peculiar and rare plant. The old spike produces flowers for a long time, and should, therefore, not be cut. SYNS. *Epidendrum Flos-aëris, Renanthera Arachnites, R. Flos-aëris.*

ARACHNIS. A synonym of **Arachnanthe** (which *see*).

ARACHNITES. In part synonymous with **Ophrys** (which *see*).

ARALIA. Bentham and Hooker include *Dimorphanthus* here. Of the thirty species comprised in this genus, six are North American, one is Mexican, and the rest inhabit Eastern or tropical Asia, from Japan and Mandschuria as far as the Himalayas and the Indian Archipelago. *See also* **Dizygotheca.**

Many of the Aralias are amongst the most decorative of plants used to furnish the outside garden. A species, however, which is not as often seen as it might be is *A. cachemirica.* This may be most effectively grown in large beds, in the shrubbery border, or as a lawn plant, where its noble appearance and beautiful foliage stand it in excellent stead. *Aralia spinosa* is another species of equal value for such purposes as suggested in connection with the lesser known *A. cachemirica.*

To the species and varieties described on pp. 104-5, Vol. I., the following should be added:

A. Balfouriana (Balfour's). *l.* abundantly produced; leaflets three on each side, sub-orbicular, emarginate at base, the medial one very large, all irregularly toothed and spotted with white on the borders. New Caledonia. A branched, tufted tree. (R. H. 1898, p. 229.)

A. cachemirica (Cashmere).* *fl.* white; umbels in elongated panicles sometimes 1ft. long, but many smaller; bracts sometimes leaf-like and 1½in. long. *l.* pinnate to tripinnate, the ultimate pinna with five to nine leaflets; leaflets 3½in. by 1½in., elliptic, shortly acuminate, often cordate at base. *h.* 5ft. to 10ft. Cashmere, 1888. A stately, hardy herb. SYN. *A. macrophylla.*

A. Chabrieri (Chabrier's), of gardens. A synonym of *Elæodendron orientale.*

A. chinensis elata (tall). The correct name of *Dimorphanthus mandschuricus.*

A. c. foliis aureo-variegatis (having golden, variegated leaves). A form, described by its name, introduced in 1896.

A. Gemma (jewel). *l.* graceful, bipinnate; pinnules with small lateral leaflets and a large terminal one, all irregularly lobed or toothed, olive-green above, greyish-violet beneath when young. New Caledonia, 1883. An ornamental stove shrub. (I. H. 1883, 477.)

A. leptophylla is now known as *Dizygotheca leptophylla.*

A. macrophylla (large-leaved). A synonym of *A. cachemirica.*

A. mandschurica (Manchurian). A synonym of *A. chinensis elata.*

Aralia—*continued.*

A. reginæ (queenly). This is of larger habit than the *Veitchii* section; the leaf branches are more closely set, and the habit of growth is very graceful; the stem and petioles are freckled; the palmate divisions of the stalk are smooth, and of a uniform green. Stove.

A. Sieboldii (Siebold's). The plant commonly grown in gardens under this name is *Fatsia japonica.*

A. triloba (three-lobed). *l.* three-lobed, each segment being nearly 1ft. long and about ¾in. across, of a deep, bright green. New Caledonia, 1896. A fine and distinct stove plant.

ARAUCARIA. SYN. *Dombeya* (of La Marck). Including *Altingia* and *Eutacta.* The known species of this genus number about ten, and inhabit South America, Australia, New Caledonia, and the South Pacific Islands. To those described on p. 106, Vol. I., the following should be added:

A. brasiliana (Brazilian). The correct name of *A. brasiliensis.*

A. elegans (elegant). A synonym of *A. brasiliana.*

A. imbricata platifolia (broad-leaved). A form with much broader leaves than in the type. 1895.

A. Muelleri (Mueller's). *l.* oval, imbricated, almost flat, longitudinally marked with small, whitish spots arranged in series. *cones* ovoid, 5½in. long, 3½in. broad; scales about 1⅞in. long and broad. New Caledonia, 1884. Plant ultimately forming a large tree, with spreading, plume-like branches. (F. & P. 1884, p. 27; I. H. ser. iv. 449.)

ARAUJIA. The correct name of the genus described on pp. 115-6, Vol. III., as *Physianthus.*

A. grandiflora (large-flowered).* *fl.* pure white, very sweet-scented, funnel-shaped, nearly 3in. across, borne in clusters of about six. September. *l.* cordate-obovate, acute. Brazil, 1837. SYN. *Schubertia grandiflora* (Gn., 30th July, 1887).

ARBORICULTURE is that phase of gardening which treats of the culture of trees. An Arboriculturist is one who cultivates trees, making them a speciality.

ARBOUR. An Arbour is always a favourite place in a garden, and may be formed under trees that naturally lend themselves to the purpose. The Weeping Ash is excellent; in fact, most of the Weeping trees are suitable. The Yew, again, Beech, and the Portugal Laurel may all be trained to form very pleasant retreats. The Arbour which finds the most favour is one made with wood or iron trellis, and covered with Roses, Clematis, Honeysuckle, Jasmine, or other sweet-scented climbers. Occasionally an Arbour is covered with Ivy or Ampelopsis, and very handsome they are on the exterior, though they make the inside somewhat dark.

ARBUSCLE. A low shrub in the form of a tree.

ARBUTUS. About ten species are referred to this genus; they are natives of Europe and North America, the genus being represented in this country by *A. Unedo.* For several species formerly included here, *see* **Arctostaphylos** and **Pernettya.**

It is very important that the soil in which the species of *Arbutus* are planted should be thoroughly well drained, as they abhor anything like stagnation at the roots. Although hardy, it is not advisable to plant them in positions exposed to cold winds or under or near large trees, as they refuse to flower freely unless the growths are properly ripened.

Propagation. Budding may be conducted with success during the month of July, taking care to use eyes only from well-matured wood. Grafting should be performed in spring, just before growth commences. After the scions have been securely tied to the stocks they should be placed in a close case, where the temperature ranges from 60deg. to 70deg. They must be shaded from the sun, and a slight syringing overhead occasionally will be of great assistance in helping them to start away more freely. When growth an inch or so in length has been made, it will be advisable to stand them in a more airy part of the house. They should be grown in pots until the following spring, and then planted out in nursery rows in a mixture of peat, loam, and leaf-mould.

Arbutus—*continued.*

A. furiens (raging). *fl.* in short axillary racemes. *fr.* a reddish-brown berry, causing delirium if eaten. *l.* oval, shortly petiolate, denticulate, shining above. Chili.

A. Milleri (Miller's). A garden hybrid, with pink flowers and large leaves.

A. phillyreæfolia (Phillyrea-leaved). A synonym of *Pernettya phillyreæfolia.*

ARCADE. An Arcade in a garden is usually a walk covered over in the form of a trellis with trees or climbers. A very fine Arcade made with trees may be seen at Hampton Court Palace, and in many gardens beautiful Arcades are made with iron and stout wire, covered with Roses or other suitable plants in the summer months. A profitable and highly ornamental Arcade could be made by planting Apple, Pear, and Plum Trees in cordon form, and training them over the trellis until they meet in the centre. By planting varieties that are known to fruit freely on cordon trees, and also by selecting sorts that produce large or handsome fruit, a fine effect is produced, alike when the trees are in blossom and in fruit; in addition to which the fruit is valuable for use.

FIG. 76. ARCHONTOPHŒNIX CUNNINGHAMII.

ARCHANGEL, YELLOW. A common name for **Lamium Galeobdolon** (which *see*).

ARCHANGELICA (from *arche*, chief, and *Angelica*, an allied genus). ORD. *Umbelliferæ.* A small genus (five species) of hardy, often tall herbs, natives of Europe,

Archangelica—*continued.*

Northern Asia, and America. Flowers white or greenish, in compound, many-rayed umbels; involucral bracts small or wanting. Leaves pinnately decompound. Only one species calls for description here. For culture, &c., *see* **Angelica.**

A. officinalis (officinal). Common Angelica. *fl.* greenish; involucel as long as the umbellets. July. *l.* bipinnately divided; segments sub-cordate, lobed, acutely serrated, the terminal one three-lobed. Europe (but not indigenous in Britain). SYN. *Angelica Archangelica.*

ARCHONTOPHŒNIX (from *archonte*, chief, and *Phœnix*; in allusion to their majestic aspect and their relationship). ORD. *Palmæ.* A small genus (two species) of tall, stove, unarmed Palms, natives of Eastern Australia. Flowers rather large, monœcious in the same spadix, spirally disposed; spadices shortly pedunculate, the branches and branchlets pendulous; spathes two, complete, caducous; inflorescence under the leaves. Leaves terminal, equally pinnatisect; segments linear-lanceolate, acuminate or bidentate at apex. Caudex marked with annular scars. The two species, *A. Alexandræ* and *A. Cunninghamii* (see Fig. 76), were formerly included under **Ptychosperma** (where they will be found described).

ARCTIA. ORD. *Lepidoptera.* A genus of gaily-coloured Moths, two species of which are found in gardens. The larvæ are destructive to Lettuce, Forget-me-Nots, and other plants. Being hairy, the larvæ are seldom taken by insectivorous birds. The Cuckoo, however, will devour them greedily. *See* **Tiger Moth.**

ARCTIO and **ARCTIUM** (of La Marck). Synonyms of **Berardia** (which *see*).

ARCTOCALYX. Included under **Solenophora** (which *see*).

ARCTOSTAPHYLOS. Bentham and Hooker include *Comarostaphylis* here, but it has been kept distinct on p. 364, Vol. I. The genus includes fifteen species, of which two inhabit the colder regions of the Northern Hemisphere, and the rest are Mexican and Californian. To the species described on p. 108, Vol. I., the following should be added:

A. nevadensis (Nevada). *fl.* reddish, ¼in. long, in simple, small clusters. Spring. *fr.* reddish, sub-acid. *l.* obovate or oval, varying to lanceolate-spathulate, cuspidate-mucronate, thicker than in *A. Uva-ursi*, abruptly petiolate. Sierra Nevada, California, 1896. A prostrate, evergreen bush.

ARCTOTIS. This genus comprises about thirty species: one is Abyssinian, and the remainder are South African. Leaves radical or alternate. To those described on p. 108, Vol. I., the following should be added. One or two species formerly included here are now referred to **Cryptostemma.**

A. arborescens is synonymous with *A. aspera.*

A. aspera (rough). *fl.-heads* yellow; outer involucral scales linear-subulate, hispid. August. *l.* commonly tomentose beneath, but sometimes naked, hispid and setose above, pinnatifid or inciso-pinnatifid; lobes toothed, broad or narrow; cauline ones dilated and amplexicaul. Stem half-shrubby, branching, hispid, scabrous or tomentose. *h.* 3ft. South Africa, 1710. SYN. *A. arborescens.*

A. a. undulata (waved). A synonym of *A. aurcola.*

A. aureola (golden). *fl.-heads* brilliant orange, 3in. to 4½in. across; involucral scales rounded at apex, black-bordered, the outer ones recurved; ray florets in two series, obtuse; peduncles woolly. April. *l.* sessile, oblong or ovate-oblong, sinuate-pinnatifid; lobes oblong or broadly ovate. South Africa, 1710. Plant erect or decumbent, white-woolly. (B. M. 6835, upper figure.) SYN. *A. aspera undulata.*

A. cuprea (coppery). A synonym of *A. aspera undulata.*

A. glutinosa (glutinous). A synonym of *Dimorphotheca cuneata.*

A. Leichtliniana (Leichtlin's). *fl.-heads* 2½in. in diameter; ray florets golden-yellow, with a dark basal mark, below flaked with red, 1¼in. long. Summer. *l.* 2in. to 8in. long, obovate or oblanceolate, petiolate, pinnatifid and toothed; lobes oblong, slightly lobulate. 1885.

A. revoluta (revolute). *fl.-heads* orange-yellow, not so brilliant as those of *A. grandiflora*, 2½in. across; outer involucral scales much narrower than in *A. grandiflora*, and having tomentose tips; the others having no black border. Cape of Good Hope, 1820. (B. M. 6835, lower figure.)

ARCUATION. Another name for **Layering** (which *see*).

ARDISIA. SYNS. *Bladhia, Pyrghus.* Including *Icacorea.* Of this genus there are about 200 species, broadly dispersed through tropical and sub-tropical regions, but very rare in tropical Africa. To those described on p. 109, Vol. I., the following should be added:

A. acuminata. *Icacorea guianensis* is synonymous with this species.

A. capitata (headed). *fl.* greenish-white, disposed in a cone-like head; peduncles axillary, compressed. Summer. *fr.* bright red. *l.* crowded at the tips of the branches, 1ft. or more long, obovate-spathulate, entire, shortly stalked. Branches thick. Fiji, 1887.

A. crenata (crenate). The correct name (B. M. 1950) of *A. crenulata* (L. B. C. 2). SYN. *A. crispa.*

A. crispa is identical with *A. crenata.*

A. excelsa (tall). A synonym of *Myrsine Heberdenia.*

A. mamillata (nippled). *fl.* white, tinged rose, star-shaped; umbels ten- to twelve-flowered, on axillary peduncles 2in. long. *fr.* brilliant rosy-red, about ⅜in. in diameter. *l.* oblong-elliptic, 4in. or more long, dark, shining green, thickly studded with small, raised dots or mamillæ on the upper surface, with proportionate hollows beneath, each mamilla surmounted by a white, bristly hair; petioles short. Hong Kong, 1837. (G. C. ser. iii., vol. ii., p. 809.)

A. metallica (metallic). *l.* tinted with violet on the upper surface. Sumatra, 1831. (I. H. xxviii., t. 421.)

A. picta (painted). *l.* lanceolate, acute, crenate at the margins, dark, velvety bronze-green, with a broad, central, feathered, silvery stripe. Brazil, 1885. An ornamental foliage plant.

A. polycephala (many-headed). *fl.* white, borne in umbels, on short, lateral branches, sometimes in a dense raceme 2in. to 4in. long; peduncles axillary, short, stout, compressed. *fr.* jet-black. *l.* opposite, elliptic or oblong, narrowed at both ends, 7in. to 9in. long, 2¼in. broad, dark, glossy green, when young bright crimson. East Indies, 1888.

A. solanacea (Solanum-like). A synonym of *A. humilis.* (B. M. 1677.)

ARDUINA. Bentham and Hooker regard this as synonymous with **Carissa** (which *see*).

FIG. 77. ARECA GLANDIFORMIS.

ARECA. According to the authors of the "Genera Plantarum," this genus now embraces about two dozen species, natives of tropical Asia, the Malayan Archipelago, tropical Australia, and New Guinea. Leaves terminal, equally pinnatisect. To the species described on pp. 109-10, Vol. I., the following should be added. Species

Areca—*continued.*

formerly included in this genus have been referred to **Bacularia, Calyptrocalyx, Chrysalidocarpus, Cyrtostachys, Dictyosperma, Dypsis, Nephrosperma, Oreodoxa, Pinanga, Prestoëa, Ptychosperma, Rhopalostylis** and **Stevensonia** (in addition to other genera mentioned in Vol. I.).

A. glandiformis. Fig. 77 illustrates the decorative character of this species in a young state.

A. laxa (loose). *fl.*, spathe solitary, marginate; spadix decompound. *l.*, leaflets lanceolate, acute, entire, equidistant. Stem 20ft. to 30ft. high, somewhat tumid, usually incurved. Andaman Islands.

A. Micholitzii (Micholitz'). *l.* large, sparsely divided. Stems 9ft. high. New Guinea, 1895.

A. macrocalyx (large-calyxed). *fl.*, spadix nodding, simply branched. *fr.* congested, ellipsoid-obtuse, umbonate. *l.*, leaflets remote, lanceolate-linear, very acute; rachis slightly furfuraceous. Stem slender, 15ft. to 20ft. high. Java.

A. elegantissima and *A. Sanderi* are rare in cultivation.

A. Buchenbergi (R. H. 1898, p. 264) and *A. Ilsemanni* (R. H. 1898, p. 261), are garden names for plants grown on the Continent, but not in general cultivation in this country.

ARENARIA. Under this genus Bentham and Hooker include *Alsine, Cherleria, Gouffeia, Minuartia,* and *Mœhringia* (the last-named is kept separate in this work). Flowers white or very rarely red, terminal, cymose-paniculate or capitate, rarely axillary and almost solitary; sepals five, rarely four; petals the same, entire or slightly emarginate, rarely wanting; stamens ten, rarely eight, or fewer by abortion. Seven species are indigenous in the British Islands. To those described on p. 110, Vol. I., the following should be added;

A. Huteri (Huter's). *fl.* pure white, large for the size of the plant, terminal and axillary in the upper leaves. Stems thickly set. *h.* about 1in. Tyrol, 1894. An attractive alpine, rockery plant. (J. H., 1894, xxix., p. 369, f. 57.)

A. muscosa (mossy). The correct name of *Mœhringia muscosa.*

A. norvegica (Norwegian).* A nearly glabrous, Scottish variety of *A. ciliata*, with rather broader sepals, shorter peduncles, and more succulent leaves, seldom fringed. It forms dense cushions about 6in. across. (F. D. 1259; Sy. En. B. 237.)

A. verna flore-pleno (double-flowered). A very pretty variety, with small, very double, white flowers; it is, however, rather delicate.

ARENBERGIA. A synonym of **Eustoma** (which *see*).

ARENGA. SYNS. *Gomutus, Saguerus.* This genus includes about half-a-dozen species of tall, stout, stove Palms, natives of tropical Asia, the Malayan Archipelago, New Guinea, and tropical Australia. Flowers fuscous- or yellowish-green or purplish, large, appearing first from an upper leaf-axil, and successively from lower ones; spadices interfoliolar, large, much branched; spathes many, clothing the peduncle of the spadix. Fruit globose-obovoid. Leaves terminal, long, pinnatisect; leaflets long, linear, usually præmorse, one-ribbed, with one or two auricles at base. To the species described on p. 110, Vol. I., the following should be added:

A. Engleri (Engler's). *fl.* said to be very fragrant; spadices much branched. *fr.* sub-globose, ½in. in diameter. *l.* consisting of numerous leaflets which are 16in. long, dark green above, silvery beneath. *h.* 5ft. Formosa, 1895.

A. Griffithii (Griffith's). A synonym of *A. saccharifera.*

A. obtusifolia (obtuse-leaved). This is distinguished from *A. saccharifera* in having bifariously-arranged leaflets with deflexed tips, the upper ones alone auricled and only on one side. Penang, &c.

A. saccharifera (sugar-bearing). *fl.*, male spadix purple, 4ft. to 5ft. long, simply branched, the flowers 1in. or less in length; female flowers solitary. *l.* numerous, 20ft. to 28ft. long; leaflets quadrifariously fascicled, as many as 115 on each side, 3ft. to 5ft. long, sub-sessile, scurfy beneath, toothed towards the tip. Trunk stout, 20ft. to 40ft. high. Assam, &c., 1829. SYN. *A. Griffithii.*

A. Wightii (Wight's). *fl.*, spadices 4ft. long; peduncles 2ft. long. *fr.* the size of a crab apple. *l.* 12ft. to 28ft. long; leaflets alternate, crowded, linear-ensiform, 3ft. to 3½ft. long, 1½in. to 2in. broad, sparingly toothed from the middle upwards; lower auricle very large, overlapping the petiole. Trunk 3ft. to 8ft. high, stout, soboliferous. Deccan Peninsula, 1882.

A. Bonnetii and *A. Listeri* are rare in cultivation.

ARGEMONE. Mexican Poppy. SYN. *Echtrus.* This genus includes about half-a-dozen species, all American, one being broadly scattered over the tropical regions of the globe. To the information given on p. 110., Vol. I., the following should be added:

A. albiflora is a variety of *A. mexicana.*

A. hispida (hispid). The correct name of *A. hirsuta.* (B. M. 6402.)

A. Hunnemanni (Hunnemann's). The showy plant known in gardens by this name is properly called *Hunnemannia fumariæfolia* (which *see.*)

ARGYLIA (named in honour of Archibald Campbell, third Duke of Argyll, who introduced many American trees and shrubs into this country). SYN. *Oxymitus.* ORD. *Bignoniaceæ.* A genus embracing about ten species of perennial herbs, confined to the Andean region of Chili and Peru. Flowers yellow, purple, or pink, variously disposed; calyx five-parted, the segments narrow; corolla-tube long, enlarged above, straight or incurved, the limb spreading, with five nearly equal lobes, or the two posterior ones smaller; stamens four, affixed to the middle of the tube. Leaves radical or alternate, digitately five- to seven- (rarely three-) foliolate; leaflets incised-toothed or twice or thrice pinnatisect. Only one species calls for mention here. It requires sandy, well-drained soil, and an intermediate temperature.

A. canescens (hoary). *fl.* bright yellow, with red streaks in the throat, sub-corymbosely disposed at the summit of the stem, and a few scattered in the axils below, 1in. long, 1½in. across; stem erect, 1ft. to 1½ft. high. July. *l.* Carrot-like, alternate, distant, whorled, 2in. to 3½in. long. Caudex fleshy, several inches in height, cylindrical. Chili, 1892. (B. M. 7414.)

ARGYREIA. About two dozen species are included in this genus: one is tropical African, and the remainder are found in the East Indies and the Malayan Archipelago. Flowers violet, red, or white, showy; sepals equal, or the inner ones much narrower; corolla funnel-shaped, the limb plicate, angled, or five-lobed; stamens included; cymes often few-flowered, pedunculate in the axils, or the upper ones corymbose-paniculate. Leaves usually large, silky, tomentose, villous, or rarely glabrous beneath. To the species described on p. 111, Vol. I., the following should be added:

A. hirsuta (hairy). *fl.* lilac; peduncles often 4in. to 8in. long; bracts prominent, linear or oblong, the outer one often petiolate and leaf-like, making the cymes pseudo-sessile. June. *l.* ovate-cordate, acute, shaggy beneath. *h.* 10ft. India, 1850. (B. M. 4946.)

A. Hookeri (Hooker's). *fl.*, corolla pink, 2in. to 2½in. long; cymes dichotomous, few-flowered; peduncles very long. *l.* 4in. to 9in. long, cordate-ovate, acute, glabrescent or somewhat hairy beneath. India.

A. tiliæfolia (Tilia-leaved). *fl.*, corolla rose-purple, 2in. to 3in. long, widely funnel-shaped; peduncles ½in. to 3in. long, one- to three-flowered. June. *l.* ovate-cordate, 1in. to 4in. in diameter, shortly acuminate or obtuse, hoary or glabrescent beneath. India, 1812. SYN. *Rivea tiliæfolia.*

ARGYRESTHIA CURVELLA. *See* **Apple Shoot Moths.**

ARGYRESTHIA NITIDELLA. *See* **Cherry Moth.**

ARGYROPHYTON DOUGLASII. A synonym of **Argyroxyphium sandwicense** (which *see*).

ARGYRORCHIS (from *argyros*, silver, and *Orchis*; alluding to the silvery network of the leaves). ORD. *Orchideæ.* A monotypic genus. The species is a stove, terrestrial Orchid, allied to **Ancectochilus** (which *see* for culture).

A. javanica (Java). *fl.* pink, small, disposed in loose, sessile spikes; scape 9in. high. *l.* petiolate, broadly ovate, 2in. long, 1½in. broad, dark, velvety olive-green, blotched lighter green, and showing faint golden reticulations, pinkish beneath. Java. (B. H. 1861, 18, under name of *Anœctochilus javanicus.*)

ARIA HOSTII. A synonym of **Pyrus Chamæmespilus Hostii** (which *see*).

ARION ATER and **ARION HORTENSIS.** *See* **Slugs.**

ARIOPSIS (from *Arum*, an allied genus, and *opsis*, resemblance). ORD. *Aroideæ*. A monotypic genus. The species is a small, stove, tuberous herb, closely allied to *Arum*. For culture, *see* **Caladium.**

A. peltata (peltate). *fl.*, spathe violet, with a green dorsal ridge, paler within, incurved, apiculate, 1in. long; spadix shorter than the spathe, decurved, dark purple and green; peduncle 1in. to 4in. long, very slender. *l.* entire, peltate, orbicular or cordate, 1in. to 6in. in diameter, rounded or acute, membranous, glaucous beneath; petioles 2in. to 7in. long. Himalayas. (B. M. 4222.) SYN. *A. protanthera.*

A. protanthera (flowering first). A synonym of *A. peltata.*

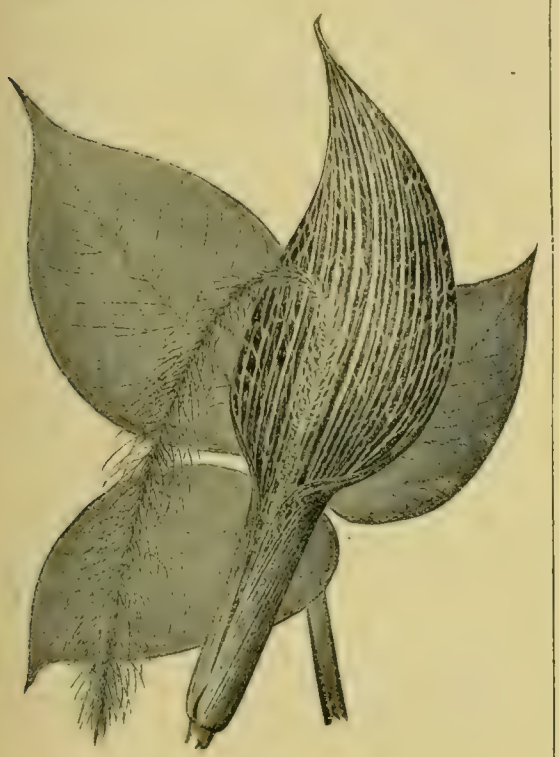

FIG. 78. INFLORESCENCE AND LEAF OF ARISÆMA FIMBRIATUM.

ARISÆMA. The fifty species of this genus are mostly natives of temperate and sub-tropical Asia, a few being North American and one Abyssinian. To those described on pp. 111-2, Vol. I., the following should be added:

A. anomalum (anomalous). *fl.*, spathe 2in. long, the tube striped purplish-brown, the limb dark brownish-purple striped with white, the lower margin forming a recurved border round the mouth of the tube; spadix appendage narrowed upwards; peduncle 9in. high. *l.* solitary, 9in. high, with three to five lanceolate leaflets 4in. to 6in. long and 1½in. broad. Rootstock Iris-like. Straits of Malacca, &c., 1890. Stove. (B. M. 7211.)

A. atrorubens (dark red). The correct name of *A. triphyllum.* SYN. *Arium triphyllum zebrinum* (B. M. 950; L. B. C. 320).

A. Bakerianum (Baker's). This is probably only a small-spathed form of *A. fimbriatum.* 1897.

A. consanguineum (related).* *fl.*, spathe green, 3in. to 7in. long, excluding the long, filiform tip, the limb broadly ovate or ovate-lanceolate, incurved; spadix hardly longer than the tube. *l.* solitary; leaflets ten to twenty, narrowly linear-lanceolate, 3in. to 16in. long, with long, capillary tips; petiole 1ft. to 4ft. long, and (as well as the peduncle) mottled with dark pink and red or brown. Tuber 1in. to 5in. in diameter. Temperate Himalayas, 1893. SYN. *A. Giraldii.*

Arisæma—*continued.*

A. Dracontium (Dragon). The correct name of *Arum Dracontium* (B. R. 668; L. B. C. 1165).

A. enneaphyllum (nine-leaved). A garden synonym of *A. flavum.*

A. fimbriatum (fringed).* *fl.*, spadix cylindrical, slender, the free end covered with slender, purplish threads; spathe brownish-purple, longitudinally banded whitish, oblong, acute or acuminate, convolute at base. *l.* two, deeply divided into three ovate, acute, glabrous segments; petioles long, pale purplish-rose, spotted purple. Philippine Islands, 1884. See Fig. 78, for which we are indebted to Mr. William Bull. (B. M. 7150; G. C. n. s., xxii., p. 689; J. H. 1886, f. 19; R. G. 1886, 357.)

A. flavum (yellow). *fl.*, spathe yellow, green, or the limb faintly purple below, 1in. to 2in. long; spadix conical, included. *l.* two; leaflets nine to eleven, 2in. to 4in. long, the lateral ones sessile, oblong or lanceolate, acuminate, the median one sessile or petiolulate; petioles 8in. to 12in. long. Rootstock globose. Temperate Himalayas, 1891. SYN. *A. enneaphyllum*, of gardens (R. G. 1891, p. 578, f. 103).

A. Giraldii (Giraldi's). A synonym of *A. consanguineum.*

A. Leschenaultii (Leschenault's). *fl.*, spathe green, with broad, dark purple bands, 3in. to 8in. long, the tube as long as the cymbiform, long-caudate-acuminate limb; spadix 4in. long, nearly cylindric. *l.* solitary; leaflets five to eleven, oblanceolate, acuminate, serrulated, 4in. to 6in. long, 1½in. to 2½in. broad; petiole 1ft. to 2ft. long, usually mottled and banded with red and brown. Tuber large. Western Ghats, 1864. SYN. *A. papillosum* (B. M. 5496).

A. Murrayi (Murray's). *fl.*, spathe 3in. to 5in. long, the tube green, striated, ¾in. to 1in. in diameter, the limb white, rather broader. *l.* solitary; leaflets five to nine, ovate- or oblong-lanceolate, acuminate, 4in. to 6in. long; petiole 10in. to 14in. long and (as well as the sub-equal peduncle) mottled with reddish-brown. Tuber large. India, 1847. Stove. (B. M. 4388; F. d. S. 1322.)

A. neglectum (neglected). *fl.*, spathe green, 3in. to 4in. long, the tube swollen at base, the limb oblong-cymbiform, acuminate, recurved at tip; spadix rather stout, much longer than the spathe. *l.* one or two; leaflets four to seven, sessile, elliptic or oblanceolate, cuspidate-acuminate, usually broadest in the middle; petioles green or clouded. Tuber globose. Ceylon, &c., 1864. SYN. *A. Wightii* (B. M. 5507).

A. papillosum (papillose). A synonym of *A. Leschenaultii.*

A. pulchrum (pretty).* *fl.*, spathe purplish, striped with green, 3in. long, the limb narrowed into a decurved tail as long as the tube; spadix much shorter than the spathe. *l.* solitary; leaflets eight to twelve, cuneate-oblanceolate, cuspidate, 4in. to 6in. long, dark green above, somewhat glaucous beneath; petiole (and peduncle) stout, clouded and speckled with pale reddish-brown. Tuber globose. India, 1879.

A. tortuosum (tortuous). The correct name of *A. curvatum* (B. M. 5931).

A. utile (useful). *fl.*, spadix purple; spathe reddish-brown, with greenish ribs and veins, the tube 3in. to 4in. long, the lamina decurved, rarely sub-erect, 3in. to 4in. across. May and June. *l.* in pairs; leaflets three, shortly and stoutly petiolulate or sessile, the middle one broader than long, 5in. to 8in. in diameter. Sikkim Himalaya, 1880. (B. M. 6474.)

A. Wightii (Wight's). A synonym of *A. neglectum.*

A. Wrayi (Wray's).* *fl.*, spathe 5in. to 7in. long, erect, the limb pale yellowish-green or lilac, with darker stripes; spadix very slender, the appendage far exserted; peduncle taller than the petioles. *l.* one to three; leaflets five to nine, petiolulate, narrowly elliptic-lanceolate, 6in. to 10in. long, 1in. to 2in. broad, the tips apiculate or filiform; petioles 1ft. to 1½ft. long, mottled green and white and dotted with red. Tuber rooting all over. Perak, 1889. (B. M. 7105.)

ARISARUM. Only three species compose this genus, which is confined to the Mediterranean region. To that described on p. 112, Vol. I., the following should be added:

A. proboscideum (proboscis-like). *fl.*, spathe erect, greyish-white and inflated below, the upper part olive-green, narrowed into a proboscis which is often 5in. long; spadix included. February.* *l.* solitary or few, 3in. to 4in. long, 1in. to 2in. broad, hastate; petioles 4in. to 6in. high, stout, cylindric. Upper Arno and the Apennines. (B. M. 6634.) *Arum proboscideum* is synonymous with this species.

A. simorrhinum (monkey's nose). *fl.*, spathe purplish, or the blade greenish; spadix appendage short, thick; peduncle shorter than the petiole. December. *l.* solitary, sagittate-ovate, triangular-sagittate, or hastate-triangular; petiole three or four times longer than the blade. Algeria, 1596. (B. M. 6023, under name of *A. vulgare.*)

A. vulgare (common), of Hooker. A synonym of *A. simorrhinum.*

ARISTEA. This genus embraces about twenty-five species, natives of tropical and South Africa and Madagascar. To those mentioned on p. 112, Vol. I., the following should be added:

A. corymbosa (corymbose). The correct name of *Witsenia corymbosa.*

A. platycaulis (broad-stemmed). *fl.*, perianth blue, the segments oblong, ¼in. long; pedicels small; inflorescence an ample panicle 3in. to 9in. long, with all the rachises much flattened, the lower branches overtopped by their subtending leaves. April. *l.*, radical ones ensiform, firm, 1ft. long, 1in. broad. 1887.

ARISTOLOCHIA. About 180 species are included here, and they are broadly dispersed over the temperate and warmer regions. To those described on pp. 112-3, Vol I., the following should be added:

A. altissima (very tall). *fl.* pale yellowish-brown, striped reddish-brown; perianth about 1½in. long, the tube gradually enlarged to the limb, which is yellow within. June to August. *l.* bright, glossy green, petiolate, 2in. to 3in. long, ovate-cordate, obtuse or acute, waved; petioles ½in. to ¾in. long. Sicily and Algeria. Half-hardy. (B. M. 6586.)

A. arborea (tree-like). *fl.* brown and purple, produced in fascicle-like panicles from the base of the trunk; calyx fleshy-coriaceous, the throat closed by an orbicular process. *l.* ample, oblong - elliptic, acuminate, obtuse at base, pinnatinerved, reticulated and pubescent beneath, shortly petiolate. Stem erect, somewhat arborescent; branches densely fuscous-pubescent. Mexico, 1862. Stove. (B. M. 5295.)

A. Bonplandi (Bonpland's). A synonym of *A. fimbriata.*

A. brasiliensis (Brazilian). *fl.* pale, reticulated and spotted with dark purple, borne on long peduncles. *l.* reniform, very obtuse, with a deep sinus and large auricles at base. Stems striated, smooth. Brazil, 1620. Stove.

A. b. macrophylla (large-leaved). The correct name of *A. ornithocephala.*

A. ciliata (ciliated). A synonym of *A. fimbriata.*

A. Dammeriana (Dr. Dammer's). *fl.*, perianth nearly 2in. long, the lower portion distended and oblique, expanding into a trumpet-shaped tube terminated by a limb which is two-lobed on one side and on the other is prolonged into a tail-like expansion; peduncles axillary, one-flowered. *l.* about 7in. long, 2½in. broad, oblong, acuminate, cordately bilobed at base. Old stems covered with corky bark. Central America, 1895. Stove.

A. elegans (elegant).* *fl.* solitary, on long pedicels; perianth tube pale yellowish-green, 1½in. long, rather inflated, the limb suddenly expanding into a nearly shallow cup, which externally is white, veined purple, and internally rich purplish-brown, with irregular, white marks. August. *l.* 2in. to 3in. long and broad, broadly reniform-cordate; petioles 1in. to 2½in. long, very slender. Brazil, 1883. Stove climber. (B. M. 6903.)

A. elegans-brasiliensis (hybrid).* *fl.* about 8in. long, of which the distended tube occupies 2½in. and is creamy-yellow, blotched with purple along the nerves; upper lip cream-coloured, purple-spotted, about 4in. long; throat of the perianth clear yellow, with purple veins. *l.* as in *A. brasiliensis*, but less glaucous. 1897. Stove. The first recorded hybrid *Aristolochia.* (G. C. 1897, xxii., p. 126, f. 36.)

A. fimbriata (fringed). The correct name of the plant known in gardens as *A. Bonplandi*, *A. ciliata* (B. M. 3756), and *A. ciliosa* (B. 90).

A. Giberti (Gibert's). *fl.* green, spotted with dark purple, axillary, solitary; peduncles half as long as the petioles. October. *l.* orbicular-reniform, very obtuse, with a deep sinus and large rounded auricles at base, pedately seven-nerved, pale beneath. Stems slender, sulcate-angular. Brazil, 1862. Stove. (B. M. 5345.)

A. gigas. Pelican Flower. SYN. *A. grandiflora* (of B. M. 4368, not Swartz).

A. glandulosa (glandular). *fl.* green and brown, rather large, axillary, solitary; lip refracted, obovate-spathulate; peduncles striated, rather longer than the petioles. May. *l.* 2½in. long, cordate-hastate, obtuse, with rounded auricles, villous on both sides; petioles 1½in. long. Cuba. Stove.

A. g. glabra (smooth). This resembles the type, but is larger, and has the stem and leaves highly glabrous. Mexico, 1846. Hardy. SYN. *A. macradenia* (B. M. 4467).

A. grandiflora (large-flowered). A synonym of *A. gigas.*

A. g. Sturtevanti (E. D. Sturtevant's).* *fl.* very large, spotted and veined with crimson; throat deep, velvety crimson, widely expanded. New Jersey, 1891.

A. hians (gaping). *fl.* bronzy-green outside, the veins and margin of the beak light yellowish-green, the inside of the broad lobe dull yellowish-green, marked purple-brown, the inside of the beak covered with brownish-purple hairs, the inside of the inflated tube pale greenish, hairy, spotted purple-brown in the upper half. September. *l.* roundish in outline, deeply cordate at base, obtusely rounded at apex, green, reticulated beneath;

Aristolochia—*continued.*

stipules 1in. in diameter, with wavy margins. Venezuela, 1887. Stove. (B. M. 7073.)

A. longicaudata (long-tailed). *fl.* creamy-white, with purple veins, large. *l.* (and habit) as in *A. brasiliensis.* British Guiana, 1890. "A handsome, robust, stove species of the unilabiate group, in which the solitary lip of the flower is prolonged into a very long tail." (G. C. 1890, viii., p. 493, f. 98.)

A. longifolia (long-leaved). *fl.* purplish-brown, of a good size; tube yellowish, with dull purplish veins outside, abruptly bent upon itself; limb roundish, about 2½in. in diameter, the lower part bent as if pinched in the middle. *l.* long, linear-lanceolate, acuminate. Stems long, climbing. Rootstock short, woody. Hong Kong, 1886. Stove. (B. M. 6884.)

A. macradenia (large-glanded). A synonym of *A. glandulosa glabra.*

A. pandurata (fiddle-shaped). *fl.* of an intense violet, lined and reticulated with paler violet or yellow, paler and unspotted outside, large, axillary, solitary; peduncles longer than the petioles. September. *l.* very variable; the lower ones usually hastate-panduriform, the upper ones hastate-cordate, acute, with a deep sinus at base. Stems woody. *h.* 10ft. Caraccas, 1823. Stove. SYNS. *A. panduriformis*, *A. picta* (F. d. S. v., p. 521; L. & P. F. G. i., p. 9).

A. panduriformis (fiddle-shaped). A synonym of *A. pandurata.*

A. picta (painted). A synonym of *A. pandurata.*

A. ridicula (ridiculous). *fl.* 3½in. to 4½in. long; tube dull whitish, veined purplish-brown, bent upon itself, the basal part inflated; limb shortly revolute, prolonged from the upper part of the sides into two long lobes, "reminding one of a donkey's ears"; they are tawny or cream, with dark purplish-brown, dendritic markings, sparsely purple-brown hairy. *l.* bright green, orbicular or orbicular-reniform, cordate at base, covered with short hairs. Stem, petioles, and pedicels clothed with spreading hairs. Brazil, 1886. Stove climber. (B. M. 6934; G. C. n. s., xxvi., p. 361.)

A. Roxburghiana (Roxburgh's). *fl.* in racemose, puberulous cymes; perianth pale green, 2in. to 2½in. long, the lip as long as the tube. September. *l.* 4in. to 8in. long, cordate, the upper ones often narrowly lanceolate, the lower ones (or all) ovate or broadly ovate-oblong, pedately five- to seven-nerved. India, 1881. Stove.

A. salpinx (trumpet). *fl.* about 1½in. long, inflated at base, then abruptly constricted and bent upwards in the form of a dorsally compressed, trumpet-shaped tube, with an oblique mouth, outside cream-coloured, with purple network of veins, inside lighter, the upper lip with a yellow central blotch and numerous purplish spots around it, the margins slightly reflexed, marked with purple lines and having a few short, purple hairs. *l.* cordate-ovate, acuminate, glabrous, 4in. to 6in. long, 2½in. to 3in. broad. Paraguay, 1886. Stove. (G. C. n. s., xxvi., pp. 456-7.)

A. Serpentaria (serpent-like). *fl.* near the base of the stem, on bracteate, spreading peduncles; calyx dull purple, three-lobed, shaped like the letter S. June to August. *l.* 2in. to 4in. long, ovate to linear-lanceolate, cordate or hastate at base, shortly petiolate. Stems pubescent, zigzag and leafy above. North America, 1632. A hardy, deciduous trailer.

A. Sturtevantii (E. D. Sturtevant's). A variety of *A. grandiflora.*

A. Westlandi (A. B. Westland's). *fl.* pendulous, chiefly produced from towards the base of the plant; perianth tube brown and yellow, cylindric, the limb pale greenish-yellow, veined and speckled purple, 6in. long, broadly rounded-ovate; peduncles 3in. to 5in. long, one-flowered. March. *l.* 6in. to 10in. long, shortly petiolate, narrowly oblong-lanceolate, acuminate, glabrous above, strongly nerved and pubescent beneath. Stem short, woody; branches tall-climbing. China, 1886. Stove. (B. M. 7011.)

ARISTOMENIA. A synonym of **Stifftia** (which *see*).

ARISTOTELA. A synonym of **Othonna** (which *see*).

ARISTOTELEA (of Loureiro). A synonym of **Spiranthes** (which *see*).

ARISTOTELIA. SYN. *Friesia.* About ten species of hardy or half-hardy shrubs are included in this genus; they are natives of Chili, Tasmania, the New Hebrides, New Zealand, &c. Flowers axillary or lateral, racemose, often polygamous; sepals and petals four or five, the latter three-lobed, toothed, or nearly entire. Berries small. Leaves often nearly opposite, entire or toothed.

As the Aristotelias are not hardy in all parts of the country, they should not be planted in the ordinary shrubbery border unless the site is a very favourable one.

Aristotelia—*continued.*

The points of the shoots are frequently damaged by light frosts, and in severe winters the growths are cut down almost to the ground. Aristotelias well deserve a place against a wall.

To the species described on p. 113, Vol. I., the following should be added:

A. Braithwaitei (Braithwaite's). This is described as a beautiful plant, having large flowers with (white?) fringed petals. It is said to be intermediate in character between *Elæocarpus* and *Aristotelia*, having the floral characteristics of the former, and the foliage and inflorescence of the latter. New Hebrides, 1881.

A. racemosa (racemose). *fl.* small; racemes panicled, many-flowered, axillary. *l.* on long petioles, membranous, pubescent, 3in. to 5in. long, ovate-cordate or oblong-lanceolate, acuminate, deeply and irregularly serrated, often red or purple beneath. *h.* 6ft. to 20ft. New Zealand, 1873.

ARM. A large branch of a Vine, trained horizontally.

ARMADILLO VULGARIS. *See* **Oniscidæ.**

ARMED. Furnished with prickles, spines, or thorns.

ARMENIACA MUME. Another name for **Prunus Mume** (which *see*).

ARMERIA. SYN. *Statice* (in part). According to some authors, the number of species is upwards of fifty: while others reduce the number to six or seven. The genus is mostly represented in Europe, North Africa, and Western Asia.

The value of the Thrifts lies chiefly in their compact tufted habit, in their adaptability for sunny situations, and their utility for edgings, *A. alpina*, *A. maritima alba*, and *A. m. Laucheana* being the best for the purpose. *A. latifolia* is commonly known as the Giant Thrift, and is very free, the flowers being large and of a nice rosy-crimson. The form Rose Beauty is, however, superior generally to the type. These last make nice pot-plants.

To the species described on pp. 113-4, Vol. I., the following should be added:

A. alliacea (Allium-like). A synonym of *A. dianthoides*.

A. alpina (alpine). A synonym of *A. vulgaris*.

A. cæspitosa (tufted). *fl.* pale lilac, in small heads; involucral leaflets brownish; scape pubescent. Summer. *l.* very short, narrow-linear, triquetrous, rigid, recurved. *h.* 1in. to 2in. Roots forming dense tufts. Mountains of Spain, 1885. The smallest of the Thrifts. (B. M. 7596; R. G. 1192, f. 2.)

A. latifolia (broad-leaved).* *fl.* disposed in a large, globose head; petals pale rose-colour, obovate; involucral bracts pale brown; scape tall. April. *l.* 3in. to 5in. long, narrow-oblanceolate, acute or acuminate at apex, gradually narrowed to the petioles, glaucescent. Portugal. (B. M. 7313.) *A. latifolia* is not synonymous with *A. cephalotes*, the correct name of which is *A. mauritanica*.

A. undulata (wavy). *fl.* white, with white bracts, borne in a large head on a tall scape. Summer. *l.*, lower ones lanceolate or lanceolate-linear, often sinuate-toothed, three-nerved; the rest linear or bristle-like, acute. Greece, 1888. Plant highly glabrous, tufted.

ARMERIASTRUM. A synonym of **Acantholimon** (which *see*).

ARMILLARIA MELLEA. *See* **Agaricus.**

ARMORACIA. Included under **Cochlearia** (which *see*).

ARMY WORM (*Leucania unipuncta*). The insect known popularly in the United States by the above name is the larva of a Moth 1½in. in wing expanse, and of a yellowish colour dotted with black. It is very rarely seen in this country. In America and elsewhere, however, it is one of the greatest pests with which the agriculturist has to contend. Like the rest of its congeners it is a Grass-feeder, though none of them are over-fastidious. The name Army Worm has been applied on account of the enormous numbers which in certain seasons swoop down upon the Grass crops. Fortunately the pest is kept in check by a host of insect parasites, or the consequences would be still more disastrous. Applications of Paris Green, and the digging of deep trenches in the fields are both successfully employed. So far as can be traced it has not done any damage in this country.

ARNEBIA. SYNS. *Dioclea*, *Meneghinia*, *Stenosolenium*, *Strobila*, *Toxostigma*. About a dozen species, natives of North Africa and Western and Central Asia, are included in this genus; they are mostly hardy, annual or perennial, hispid herbs. Flowers yellow or violet, sub-sessile, in simple racemes or branched cymes; calyx five-cleft or five-parted; corolla tube straight, the five lobes imbricated, spreading; stamens included. Leaves alternate. Roots tinged with red. To the species described on p. 114, Vol. I., the following should be added:

A. cornuta (having horns). *fl.* deep yellow, having at first five black spots at the base of the lobes, which change to brown and finally disappear; raceme erect, leafy. *l.* lanceolate, dark green, hairy; lower ones obtuse; upper ones acute. *h.* 1½ft. Afghanistan, 1888. A pretty annual.

A. macrothyrsa (large-thyrsed). *fl.* yellow, produced in dense trusses. *l.* 4in. to 7in. long. *h.* 1ft. to 1½ft. Armenia, 1891. A fine, showy perennial.

ARNICA. There are about ten species of this genus, natives of Europe, Asia, and North America. Flower-heads yellow, large, radiate, heterogamous, borne on long peduncles; involucral bracts in one or two series, acuminate. Leaves usually crowded at the base of the stem, opposite, entire or toothed. *See also* **Aster, Doronicum,** and **Mairia.**

A. montana is a very choice plant for the rockery or for the front of the mixed border. It is one of those Composites which are best grown in a sunny spot, when its orange-yellow flower-heads will be plentifully produced.

ARNOPOGON. A synonym of **Urospermum** (which *see*).

AROMIA MOSCHATA is the name by which the elegant Musk Beetle is known to science. In Vol. II. of this work the insect is fully described, and this description, together with the illustration (Fig. 79), will enable the gardener to readily identify the insect. It affects tree-trunks in the daytime, but gets more active as evening approaches. These wood-feeding insects are very objectionable by reason of the fact that the larvæ remain in that condition considerably longer than is the case with insects generally. When captured these Beetles emit a noise which has been translated into a squeak, but which in reality is the result of friction, as already noted. If these Beetles are left in undisturbed possession, they will in time so tunnel the tree in every direction that little of the heart-wood remains. *See also* **Musk Beetle.**

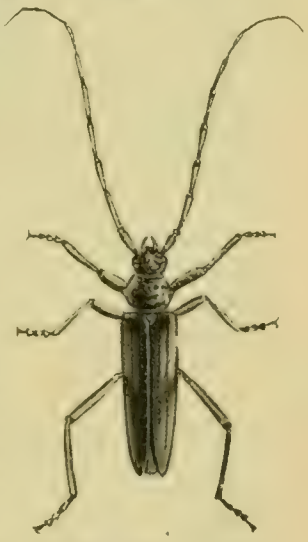

FIG. 79. MUSK BEETLE (*Aromia moschata*). (Natural size.)

ARRACACIA is the correct name of *Arracacha*. The genus embraces about a dozen species of perennial herbs, all American. Flowers white; involucral bracts leafy or wanting. Leaves pinnate or pinnately decompound.

ARSENITES. Two of the most valuable Arsenites of Copper and of Lime respectively are at the present day employed as insecticides in the form of **Paris Green** and **London Purple** (which *see*). Both compounds are virulent poisons.

ARTABOTRYS. This genus includes about fifteen species of sarmentose or climbing, stove shrubs, natives of tropical Asia and Africa. Flowers solitary or fascicled; sepals three, cohering at base; petals six, free; stamens numerous; peduncles often hard, hooked.

ARTANEMA. SYNS. *Archimenes* (of Vahl), *Diceros.* This genus embraces three species (closely related), natives of tropical Asia and Australia. *A. fimbriatum* is the only one introduced.

ARTEMISIA. Including *Absinthium.* This genus embraces about 150 distinct species (about 200 have been described as such), mostly natives of the Northern hemisphere, but a few are found in South America and the Sandwich Islands. Four are indigenous in Britain. To those described on p. 115, Vol. I., the following should be added:

A. Absinthium (Absinthium). Common Wormwood. *fl.-heads* dingy yellow, rather large, hemispherical, drooping; ray florets very short; panicles erect, leafy. August. *l.* bipinnatifid, clothed with short, silky down; segments lanceolate. *h.* 1ft. to 1½ft. Europe (Britain). *See* **Wormwood.**

A. tridentata (three-toothed). *fl.-heads* densely paniculate; outer bracts short, tomentose-canescent. *l.* cuneate, obtusely three-toothed or three-lobed, silvery, persistent. *h.* 1ft. to 12ft. North America, 1894. A thick-growing bush.

ARTHROCHILUS. A synonym of **Drakæa** (which *see*).

ARTHROPTERIS TENELLA. A synonym of **Polypodium tenellum** (which *see*).

ARTHROSOLEN (from *arthron*, a joint, and *solen*, a tube). ORD. *Thymelæaceæ.* A genus comprising ten species of greenhouse shrubs, with the habit of *Wikstræmia* or *Gnidia*, natives of South Africa, one extending into the tropics. Flowers hermaphrodite, disposed in spikes or heads; stamens eight, rarely ten. Leaves sparse, flat. *A. laxus* and *A. spicatus* (L. B. C. 755 and 311, under names of *Passerina laxa* and *P. spicata*) have been introduced, but are probably lost to cultivation.

ARTHROSTEMMA. SYN. *Heteronoma.* Six species, natives of Mexico, Venezuela, Peru, Colombia, and the West Indies, form this genus. *See also* **Brachyotum.**

ARTHROZAMIA. A synonym of **Encephalartos** (which *see*).

ARTICHOKE, JERUSALEM. *Varieties:* Until recently only the old well-known Jerusalem Artichoke was grown; this will probably be superseded by a variety named the New White. This sort is as prolific as the old one, the tubers are of better form and paler in colour, and are also considered by many to be of better flavour.

ARTOCARPUS. SYN. *Sitodium.* This genus includes about forty species, natives of tropical Asia. Flowers small, very numerous, in globose or oblong, crowded heads; peduncles axillary, solitary. Leaves alternate, ample, penniveined, entire or pinnately few-lobed.

A. Cannoni. The correct name is *Ficus Cannoni.*

A. integrifolia is known as the Jaca or Jack-tree. (B. M. 2833-4.)

ARUBA. A synonym of **Almeida** (which *see*).

ARUM. As at present arranged this genus includes about two dozen species, natives of Europe, the Mediterranean region, and Western Asia as far as Afghanistan. To those described on p. 118, Vol. I., the following should be added. A number of species formerly classed under this genus are now referred to **Amorphophallus, Arisæma, Arisarum, Biarum, Caladium, Helicodiceros, Sauromatum, Synantherias, Typhonium, Xanthosoma,** &c.

A. corsicum (Corsican). A synonym of *A. pictum.*

A. detruncatum (abruptly cut). *fl.*, spathe greenish-yellow, spotted with purple, the blade lanceolate, acuminate, three times as long as the tube; peduncle much shorter than the petioles. *l.* hastate, the posterior lobe sometimes almost horizontally truncate. Asia Minor, 1889.

Arum—*continued.*

A. Dioscoridis (Dioscorides').* *fl.*, spathe varying in colour, the tube oblong, the blade oblong-lanceolate. *l.* hastate or sagittate, the oblong- or ovate-triangular anterior lobe sometimes twice as long as the posterior one; petioles twice or thrice as long as the leaves. *h.* 1ft. Levant.

A. D. Smithii (Smith's). The correct name of *A. spectabile* (R. G. 1872, t. 742).

A. D. spectabile (remarkable). *fl.*, "spathe reddish-purple passing into green above with spots, 20in. long; peduncle 3ft. high. *l.* much undulated." (Kew Bulletin, 1898, App II.)

A. Dracunculus. The correct name is *Dracunculus vulgaris.*

A. D. syriacum (Syrian). *fl.*, spathe dark purple below, pale purple in the middle, spotted with dark purple, greenish above; spadix appendage cylindrical. Syria, 1859. SYN. *A. Liepoldii.*

A. elongatum (lengthened). A form of *A. orientale.*

A. gratum (pleasing). A form of *A. orientale.*

A. hygrophilum (moisture-loving). *fl.*, spathe tube purple or whitish at base, ovoid, the limb pale green, margined with purple, more or less acuminate, about 2½in. long; spadix appendage purple, 2in. long; peduncle 8in. to 12in. long. *l.* elongated-sagittate-hastate; petioles nearly three times as long as the blade. Syria, &c., 1860.

A. italicum. SYN. *A. numidicum.* A vigorous form, introduced in 1894, is known as *A. modicense.*

A. Liepoldii (Liepold's). A synonym of *A. Dracunculus syriacum.*

A. Magdalenæ (Magdalen's). This is very closely allied to *A. palæstinum*, but has a yellow spathe, marbled and spotted with purple. Palestine, 1894.

A. modicense (Modica). A form of *A. italicum.*

A. numidicum (Numidian). A synonym of *A. italicum.*

A. orientale. The following varieties may be mentioned:

A. o. elongatum (lengthened). *fl.*, spathe purplish outside, margined with purple on the inside, long-acuminate. Caucasus, 1882.

A. o. gratum (pleasing). *fl.*, limb of the spathe of a pleasing greenish-yellow, with purple markings. Lebanon, &c., 1859.

A. o. Petteri (Petter's). *fl.*, spathe oblong-lanceolate, acuminate, pale greenish-yellow with a broad purple margin, or wholly purple. Dalmatia, 1860.

A. Petteri (Petter's). A form of *A. orientale.*

A. philistæum (Philistian). *fl.*, spathe tube whitish within, the blade saturated with purple and spotted, four times as long as the tube; spadix much shorter than the spathe; peduncle 6in. to 8in. long. *l.* hastate-sagittate, 6in. to 8in. long, with very prominent nerves; petioles 10in. to 12in. long. Palestine, 1859.

A. proboscideum. The correct name is *Arisæma proboscideum.*

A. sanctum (sacred). *fl.*, spathe of a velvety blackish-purple, large; spadix black; peduncle long. *l.* large, cordate-triangular. Tuber large and flat. Palestine, 1889.

A. spirale. The correct name is *Cryptocoryne spiralis.*

ARUNCUS. *See* **Spiræa Aruncus.**

ARUNDINA (a diminutive of *Arundo*; in allusion to the Reed-like stems). ORD. *Orchideæ.* A small genus (about five species) of erect, terrestrial, leafy Orchids, natives of the East Indies, South China, and the Malayan Archipelago. Flowers rather large, in terminal, loose, simple or rarely divided racemes; sepals sub-equal, free, spreading; petals similar or broader; lip erect at the base of the rather long, erect column, which is surrounded by the lateral lobes. Leaves flat, narrow or rather broad, sessile, with articulated sheaths. Stems erect, Reed-like, invested with the leaf-sheaths. Pseudo-bulbs wanting. The species introduced should be grown in a cool part of the East Indian house. Rough, fibrous peat and loam form the best compost, as the plants are devoid of pseudo-bulbs, and require richer soil than many other Orchids. Copious supplies of water and plenty of light, but shading in hot sunshine, are essential to success in the culture of Arundinas. Propagation may be affected by divisions, or by potting the young plants that are produced on the stems.

Though some six species of this genus are known, only one, *A. bambusæfolia*, is at present in cultivation. This requires a light position in the Dendrobium-house, where only the bright rays of the sun are broken sufficiently to prevent scorching. During the growing season abundance of moisture, both at the roots and in the atmosphere, is required, with cooler conditions during the resting period.

Arundina—*continued.*

Belonging to the terrestrial class of Orchids, the potting-compost should consist of good fibrous peat and loam, to which should be added a liberal sprinkling of rough sand or broken crocks to keep the material in a porous condition. The drainage also should be ample, so that there may be no possibility of stagnation.

A. bambusæfolia (Bamboo-leaved). *fl.* large; sepals and petals pale magenta-rose; lip rose, striped orange on either side the white throat. July to autumn. *l.* pale green, ensiform. Stems 3ft. to 5ft. high. Nepaul, Birma, &c. (B. M. 7284; W. O. A. iii. 139.) SYNS. *Bletia graminifolia, Cymbidium bambusæfolium.*

A. densiflora (dense-flowered). *fl.* rosy-violet, as large as those of *B. bambusæfolia*, scented, the lip bordered crimson; racemes close, head-like. *l.* lanceolate, sub-equal, sheathing. Stems 3ft. high. Singapore, 1842. (B. R. 1842, 38.)

A. Philippi (Philipp's). This is closely related to *A. bambusæfolia*, but is distinguished in having narrower leaves and smaller flowers; the latter are pale lavender, 1½in. across, with a blotch of crimson on the lip. 1895.

ARUNDINARIA. SYNS. *Ludolfia, Macronax, Miegia, Triglossum.* Including *Thamnocalamus.* This genus includes about two dozen species, natives of Asia and America, and mostly tropical. To those described on p. 118, Vol. I., the following should be added. For exhaustive information on the genus and its allies the reader is referred to A. B. Freeman-Mitford's excellent work "The Bamboo Garden" (London, 1896). *See also* **Bambusa.**

A. anceps (two-edged).* This principally differs from *A. nitida* in the leaf-sheaths having a circular fringe of short, bristly white hairs at the insertion of the leaf, and in the stems, purple at first, ripening to a greenish-brown tint. Origin unknown.

A. aristata (bristly). *l.* bright green, slightly glaucous beneath, 4in. long, ¼in. to ⅜in. broad, acuminate, slightly serrated, prettily tessellated; sheaths fringed with short, silky hairs. Stems 8ft. to 12ft. high, purplish-brown; nodes rather prominent. Himalayas.

A. auricoma (golden-haired).* *l.* 5in. to 7in. long, 1in. broad, "pinched in" about ½in. from the sharp point, rounded at base, boldly striped with bright yellow, serrated, velvety beneath; petioles well defined; sheaths hairy at base. Stems 3ft. high, ¼in. thick, purple, fistulous; nodes prominent, 3in. to 5in. apart. China and Japan. An ornamental, dwarf species, with which *A. Maximowiczii* is probably identical. SYN. *A. Fortunei aurea.*

A. chrysantha (golden-flowered). *l.* tessellated, 5in. to 7in. long, ½in. to ⅝in. broad, showing slight variegation; sheaths very hairy on one edge. Stems 5ft. or more in height, fistulous, very slender; nodes not prominent, having a sharp lower rim; branches numerous. China and Japan. This plant is quite hardy.

A. Falconeri (Falconer's). *l.* 3in. to 6in. long, oblong-lanceolate, thin, pointed, slightly serrated, petiolate, with striated venation on the upper surface. Stems tall, ¼in. to ⅜in. thick, smooth when young, scurfy-white when old, often striped with yellow and green; nodes raised; internodes 8in. to 15in. long; branches many at the nodes. Temperate Himalayas. SYNS. *Bambusa gracilis* (of gardens), *Thamnocalamus Falconeri.*

A. Fortunei (Fortune's).* *l.* about 5in. long, ½in. to ¾in. broad, serrated, pinched in towards the point, rounded at base, tessellated, bright green, with a well-defined, white-striped variegation; petioles white. Stems round, fistulous, green, erect, about 3ft. high; nodes often hidden by the overlapping sheaths; branches long, solitary or in pairs. China. SYN. *Bambusa Fortunei.* There are two varieties: *variegata* and *argentea vittata.*

A. F. aurea (golden). A synonym of *A. auricoma.*

A. F. viridis (green). A synonym of *A. humilis.*

A. gigantea (gigantic). A synonym of *A. macrosperma.*

A. Hindsii (Hinds'). *l.* at first erect, at length nodding, some of them attaining 9in. in length and ⅜in. in breadth, glaucous-green, tapering to a rather long petiole, pinched in about 1in. from the sharp point, thicker than usual, slightly hairy, serrated; sheaths slightly hairy on the top. Stems 7ft. or more in height, erect, round; nodes rather long, flat below, prominent above; internodes 3in. to 7in. long, covered with a white, waxy secretion. Hong Kong, 1894. SYN. *Bambusa erecta.*

A. H. graminea (Grass-like). This has narrower leaves and shorter stems than the type. 1894. SYN. *Bambusa graminea.*

A. humilis (dwarf). *l.* paler than usual, smooth, serrated, 4in. to 6in. long, ¾in. broad, finely pointed at apex, rounded at base; petiolate. Stems slender, 2ft. to 3ft. high, fistulous, round; nodes not very prominent; internodes 2in. to 5in. long; branches very long. China and Japan. SYN. *A. Fortunei viridis.*

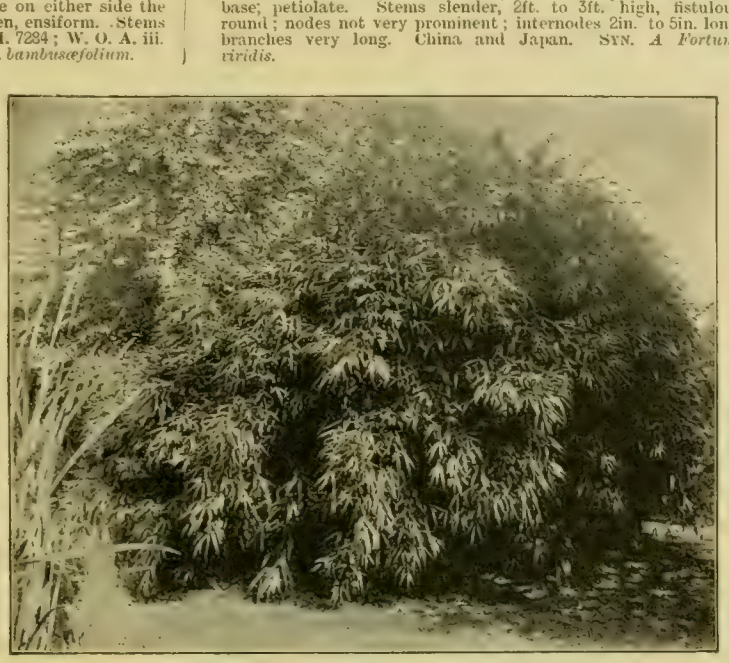

FIG. 80. ARUNDINARIA JAPONICA.

A. japonica (Japanese). The correct name of *A. Metake.* See Fig. 80.

A. khasiana (Khasia Hills). *l.* 3in. to 4in. long, ¾in. broad, linear-lanceolate, glandular between the nerves, not (or hardly) tessellated. Stems annual, dark green or blackish; nodes prominent; branchlets fascicled, dark-coloured. Khasia Hills. Closely allied to *A. falcata.* The *A. khasiana* of gardens is synonymous with *A. nitida.*

A. macrosperma (large-seeded). *l.* lanceolate, acuminate, 1in. to 2in. wide, smoothish, rounded at base, petiolate, tessellated. Stems arborescent, from 10ft. to 20ft. high, rigid, simple the first year, branching the second, afterwards at indefinite periods fruiting, and soon after decaying. United States, 1800. SYNS. *A. gigantea, Bambusa Hermanni, B. Neumanni.*

A. metallica (metallic). *l.* spreading, 6in. to 9in. long, 1½in. across, acutely pointed, deep green, with a very pale midrib. Stems stout, carrying about half-a-dozen leaves towards the apex. 1898. A dwarf-growing species.

A. nitida (shining).* *l.* 2in. to 3in. long, ¼in. broad, brilliant green, lancet-shaped, serrated, especially on one edge; petioles almost wanting; sheaths purple, downy. Stems 8ft. or more in height, ¼in. thick, deep blackish-purple, branching the second year, each branch bearing four leaves. China and Japan, 1894. SYN. *A. khasiana* (of gardens).

A. nobilis (noble). *l.* linear-lanceolate, 2in. to 3in. long, ¼in. to ½in. broad, tapering to a point, slightly serrated, purple-edged, borne on dark purple petioles. Stems round, slender, straight, yellowish, with purple-brown nodes; internodes about 7in. long. Native country unknown.

A. pumila (dwarf). *l.* about 5in. long, ½in. to ¾in. broad, abruptly pointed at apex, rounded at base, petiolate, tessellated, serrated, bright green, rather rough. Stems 1½ft. or more in height, round, fistulous, very slender, not much branched; nodes not prominent, but well defined, with a waxy deposit on the under-side; internodes about 2½in. long. China and Japan. This species is quite hardy.

A. racemosa (racemose).* *l.* 4in. to 7in. long, ½in. to ⅝in. broad, linear-lanceolate, tessellated, scabrous-serrulated, rounded or narrowed into very short petioles, glabrous or scarcely hairy

Arundinaria—*continued.*

above. Stems erect from a long rhizome, 5ft. to 15ft. high, ¾in. to 2in. thick, the nodes mere rings; internodes blue-green when young; branches fascicled at the nodes. India.

A. Simoni (Simon's).* *l.* tessellated, variable in size, usually about 10in. long and ¾in. broad, green above, glaucous below, serrated, finely pointed. Stems 13ft. high or more, round, furnished from top to bottom with sheaths, the upper edges of which are fringed. China and Japan, 1862. (B. M. 7146.) SYNS. *Bambusa Simoni, B. Narihira.* See Fig. 81, for which we are indebted to the "Gardeners' Chronicle."

FIG. 81. ARUNDINARIA SIMONI.

Arundinaria—*continued.*

A. S. striata (striped). *l.* striped with silvery variegation. Stems dwarfer than in the type. SYNS. *Bambusa Maximowiczii, B. plicata.*

A. spathiflora (spathe-flowered). *l.* two to four at the ends of the branches, 3in. to 5in. long, ½in. to ¾in. broad, linear-lanceolate, tessellated, acute at apex, narrowed at base, shortly petiolate, hairy. Stems 12ft. to 20ft. high, ½in. to ¾in. thick, smooth, glaucous-green and scurfy when young, yellow or reddish-brown when old; nodes prominent; internodes 6in. to 15in. long; branches principally from the upper nodes. Western Himalayas. SYN. *Thamnocalamus spathiflorus.*

A. Veitchii (Veitch's).* *l.* tessellated, 7in. long, 2½in. broad, green above, glaucous beneath, much serrated, rounded at base, pinched in towards the apex and ending in a sharp point; petioles purple above, yellow below. Stems about 2ft. high, ½in. thick, rich purple; nodes not very prominent; internodes 3in. to 4in. long.

ARUNDINELLA (a diminutive of *Arundo*, the name of an allied genus). SYNS. *Acratherum, Brandtia, Goldbachia, Thysanachne.* ORD. *Gramineæ.* A genus comprising about two dozen species of tall or dwarf Grasses, diffused over tropical regions. Spikelets acute or acuminate, twin at the sides of the branchlets; glumes four; panicle terminal, variable. Leaves flat, flaccid. *A. anomala*, introduced from Japan in 1889, is described as a hardy, dwarf Grass, suitable for lawns, and only requiring to be cut twice a year.

ARUNDO. Indian Grass; Lady's Laces; Painted Grass; Water Reed. SYNS. *Amphidonax, Donax, Scolochloa.* There are six or seven species of this genus, natives of the Mediterranean region, India, America, New Zealand, &c. To those described on pp. 118-9, Vol. I., the following should be added:

A. madagascariensis (Madagascar). A tall Reed, growing from 10ft. to 20ft. high, and bearing feathery panicles similar to those produced by Pampas Grass. Asia, Africa, and Madagascar, 1893.

A. Phragmites (Phragmites). A synonym of *Phragmites communis.*

ASAGRÆA. A synonym of **Schœnocaulon** (which *see*).

ASAPHES. A synonym of **Morina** (which *see*).

ASARINA. Included under **Antirrhinum** (which *see*).

ASARUM. SYN. *Heterotropa.* According to W. B. Hemsley (G. C. April 5th, 1890), this genus now includes about eighteen species, mostly natives of North temperate regions. Flowers terminal, solitary, shortly pedunculate; stamens twelve (rarely eight?); filaments rather thick or very short. Leaves usually long-stalked, cordate, reniform, or almost

Asarum—*continued.*

hastate. To the species described on p. 119, Vol. I., the following should be added:

A. albivenium (white-veined). This species is similar to *A. (Heterotropa) parviflora*, but has longer-stalked, yellowish flowers with red spots and white-veined leaves. Japan, 1864. (R. G. 1864, t. 440.) SYN. *A. leucodictyon.*

A. caudigerum (tail-bearing). *fl.* green, speckled with red and reddish-brown; perianth tube villous within, the lobes triangular-ovate, each narrowed into a slender tail 1in. or more in length; peduncle shorter than the petioles. January. *l.* two, radical, 2in. to 3in. long, broadly ovate-cordate, with a deep, narrow sinus. Southern China, 1890. Plant stemless, clothed with long hairs. Cool greenhouse. (B. M. 7126.)

A. geophilum (earth-loving). *fl.* purplish-brown, margined and spotted with white, solitary, very shortly pedunculate, about 1in. in diameter, scarcely appearing above the surface of the ground. December. *l.* cordate-orbicular, somewhat fleshy, 2in. to 4in. across, dark shining green veined with white on the upper surface. South China, 1888. Cool greenhouse. (B. M. 7168.)

A. Hookeri (Hooker's). The correct name of *A. caudatum.*

A. japonicum (Japanese). A synonym of *A. Thunbergii.*

A. leucodictyon (white-netted). A synonym of *A. albivenium.*

A. macranthum (large-flowered).* *fl.* of a rich purplish-brown, about 2in. in diameter, seated close to the ground, and so numerous that they cover the surface, the broad, much-undulated, spreading lobes of the perianth bordered with yellowish. *l.* 4in. to 5in. across, borne well above the flowers, on stout stalks, shining green above, mottled with white and paler beneath, with prominent red veins. Eastern China and Formosa, 1877. Greenhouse. This species has a pleasant odour, like Fenugreek. (B. M. 7022.)

A. maximum (largest). *fl.* maroon-purple, with a conspicuous eye-like blotch of white, fleshy, three-lobed, 2½in. in diameter, borne on short stalks. *l.* cordate, 1½ft. high, 8in. in diameter, dark green, mottled with grey much in the same manner as a Cyclamen. Rhizome creeping. China, 1895. (B. M. 7456.)

A. parviflorum (small-flowered). The correct name of *Heterotropa parviflora.*

A. Thunbergii (Thunberg's). The correct name of *Heterotropa asaroides.* SYN. *A. japonicum.*

ASCARICIDA. Included under **Vernonia** (which *see*).

ASCIDIUM (*pl.* Ascidia). A hollow, pitcher-like leaf, *e.g.*, that of *Sarracenia.*

ASCIUM. A synonym of **Norantea** (which *see*).

ASCLEPIAS. About sixty species are included in this genus, the majority being North American; a few are found in Central and South America, two in Africa, and one is broadly distributed over the warmer regions of the globe. To those described on pp. 119-20, Vol. I., the following varieties should be added:

A. acuminata is synonymous with *A. rubra.*

A. amœna is synonymous with *A. purpurascens.*

A. atrosanguinea aurea (blood-coloured and golden). This ornamental plant appears to be a variety of *A. curassavica* with deep blood-red flowers, having a yellow corona. Bolivia, 1883.

A. decumbens (decumbent). A variety of *A. tuberosa.*

A. incarnata pulchra (pretty). A form with copious and somewhat hirsute pubescence, and usually broader leaves (lanceolate to oblong), often sub-cordate at base. North America. (S. B. F. G. ser. ii., t. 18, under name of *A. pulchra.*)

A. pulchra (pretty). A form of *A. incarnata.*

A. speciosa (showy). The correct name of *A. Douglasii.*

A. syriaca. The correct name is *A. Cornuti.*

A. tuberosa decumbens (decumbent). *fl.* in umbels from most of the upper axils, racemosely disposed. *l.* broader and more commonly opposite than in the type. Stems reclining. North America, 1680. (S. B. F. G. ser. ii., t. 24, under name of *A. decumbens.*)

ASCOCHYTA. A genus of fungi belonging to the *Sphæropsideæ*, probably representing phases in the life cycle of ascigerous fungi. The chief outward characteristic of this genus is a spotting of the parts affected—leaves, stems, or, in the case of leguminous plants, the pods. The Garden Pea and the French Kidney Bean are both liable to attack from *A. pisi*, the spots appearing on leaves and pods. Generically the fungus may be briefly described: Conidia roundish, two-celled, hyaline; pycnidia embedded in the injured parts, which, in addition,

Ascochyta—*continued.*

are sometimes surrounded by rings. Other species infest the hardy *Aspidistra*, the Raspberry, the Strawberry, and the Petunia. Spraying with sulphide of potassium (½oz. to the gallon of water) is probably the best preventive.

ASCOMYCETES, or SAC FUNGI. A group of fungi characterised by the spores being produced in cylindrical sacs, scientifically known as asci. To this group belong the Mildew Fungi (*Erysipheæ*), the esculent Truffles (*Tuberaceæ*), and the *Pyrenomycetes*, several kinds of which destroy not only forest trees, but also Vines and fruit trees. Indeed, to the last-named order belong the genera responsible for the Anthracnose of the Vine, the Canker of Apple and other trees, and the ergot of economic value because of its medicinal properties. The last order of this group is *Discomycetes*, to which belong the genera causing the Blotch Disease of Maples, the peculiar Pocket, Mock, or Bladder Plums, the disfiguring and debilitating Peach-Curl, the Witches' Brooms of the Cherry, and many others less noteworthy.

ASCYRUM. Five species, found in North America and the Antilles, are referred to this genus.

ASEXUAL. Having no sex; *e.g.*, flowering plants that have neither stamens nor pistil.

ASH BARK SCALE (*Chionaspis fraxini*). Though commonly known by the name above adopted, this familiar insect almost as often frequents Willows, Alders, and other plants. The genus to which it belongs is a destructive one, and in certain seasons the active and conspicuous red larvæ may in late spring be found in myriads on tree-trunks which recently gave them birth. The larvæ form scale-like coverings, and then are inactive. They moult several times before arriving at the perfect stage. The females differ considerably from the males. First, they are inactive creatures destitute of wings; secondly, they are responsible for the damage to the trees by extracting the juices by means of their rostra, the males not being provided with a mouth. Usually, the males are winged, though they are seldom seen; but sometimes with this genus there are wingless males, whose functions are simply to perpetuate their kind and die. The females never move once the perfect insect stage is reached; indeed, they are absolutely incapable of so doing. They affix themselves to the spot on which the eggs are to be deposited, and there die, the shrivelled body combining with the covering elaborated to form a protection for the bright red eggs.

These insects appear in such vast numbers in certain seasons that they cause no little damage to the trees. Where, therefore, Ash or other trees, used in the decoration of gardens, are attacked by this Scale, they should be treated to kerosene emulsion during the latter part of May, by which time the larvæ have usually not begun to elaborate their protective covering, and are thus readily killed by contact.

ASH MIDGE. *See* **Diplosis.**

ASH, SOUTHERN PRICKLY. *See* **Xanthoxylum Clava-Herculis.**

ASILUS CRABRONIFORMIS. *See* **Hornet Fly.**

ASIMINA. SYN. *Orchidocarpum.* This genus embraces seven or eight species, all American. Leaves penniveined.

A. triloba is the Papaw or Custard Apple of the United States. SYN. *Anona triloba* (B. M. 5854).

ASPARAGUS. Bentham and Hooker include *Myrsiphyllum* hereunder, but it has been kept distinct in this work. The genus comprises nearly 100 species, broadly dispersed over the temperate and warmer regions. To those described on pp. 122-3, Vol. I., the following should be added. Except where otherwise stated, warm

Asparagus—*continued.*

greenhouse treatment is required. For further information, see the "Gardener's Chronicle," February 26th, March 12th and 26th, 1898.

In addition to the manures previously recommended for Asparagus, mention should now be made of kainit and nitrate of soda: 2oz. of the former and 1oz. of the latter should be mixed together and applied to each square surface yard of the beds. This dressing may be given two or three times during the growing season.

A. acutifolius (acute-leaved). *fl.* yellow, ¼in. across. *fr.* deep crimson, pea-like. *l.* grey-green, hair-like, rigid, tufted, becoming almost spinous in exposed situations. Stems hard, wiry, brown, about 5ft high; branches rigid, 3in. to 6in. long. South Europe, 1640. Hardy perennial. (S. F. G. 337.)

A. æthiopicus (African).* *fl.* white, in racemes 2in. to 3in. long. *fr.* globose, ¼in. in diameter, one-seeded. *l.* flat, falcate, rigid, bi- or ternate, ascending, mucronate, ¼in. long. Stems woody, terete, climbing, 10ft. long; branchlets short, strongly angled; prickles large, pungent. South and tropical Africa, 1816.

A. æ. natalensis (Natal). *fl.* loosely panicled. *l.* larger, less rigid, darker green.

A. æ. ternifolius (ternate-leaved). This is a synonym of *A. falcatus.* (G. C. 1893, xxiii., p. 123, f. 47.)

A. africanus (African). *fl.* white, small, star-shaped, generally produced in axillary umbels. *fr.* globose, ¼in. in diameter, one-seeded. *l.* densely clustered, rigid, subulate, about ¼in. long, persistent. Stems 12ft. long, woody, terete, much-branched, sarmentose; branchlets slightly zigzag; main prickles large, pungent. South Africa, 1819.

A. a. dependens (hanging down). *l.* shorter and stouter than in the type. Branches deflexed, often pubescent.

A. albanensis (Albanian). A variety of *A. plumosus.*

A. asiaticus (Asiatic). *fl.* white, few, axillary, small. *fr.* globose, ¼in. in diameter, one-seeded. *l.* subulate, rigid, ascending, ¼in. to ½in. long, three to twelve in a cluster. Main stem 30ft. long, slender, green, sarmentose; main prickles small; branches long. Asia and Africa, 1759. A vigorous climber, requiring a somewhat shaded position.

A. Buchanani (Buchanan's). *fl.* white, campanulate; racemes 1½in. to 2in. long, loose-flowered. *l.* ¾in. long, very narrow-linear, ascending, elongated. Branches slender, glabrous; spines hard, pungent, ¼in. long. Shiré Highlands, Tropical Africa, 1893. Plant shrubby, broadly sarmentose.

A. comorensis (Comoro).* This resembles *A. plumosus* in general appearance, but differs mainly in its more robust habit, darker green colour, and the soft texture of its leaves. Comoro, 1833. (G. C. 1893, xxiii., p. 131, f. 72.)

A. crispus (curled). The correct name of *A. decumbens.*

A. declinatus (declinate). *fl.* white, very small, campanulate. *fr.* small, globose, one-seeded. *l.* slender, subulate, bright green, ¼in. to ½in. long, six to ten in the lateral clusters, as many as twenty in those at the tips and bases of the branchlets; main leaves produced into a deltoid spur. Stems sarmentose, glabrous, woody, terete; branches decompound, with numerous spreading or deflexed branchlets. South Africa, 1759. Half-hardy.

A. deflexus (deflexed). *fl.* striped with brown, small, solitary or in clusters of two to six. October. *l.* ¼in. long, in clusters of six to ten; main ones forming a short, deflexed spur. Branches slender, the lower ones deflexed; branchlets very short. Angola, 1892. A hardy, much-branched shrub.

A. grandiflorus (large-flowered). A synonym of *A. umbellatus.*

A. laricinus (Larch-like). *fl.* white, small, campanulate, axillary, many in a cluster. May. *fr.* dull red, globose, one-seeded, ⅛in. in diameter. *l.* subulate, rigid, densely clustered, ascending ¾in. to 1½in. long, bright green. Stems 12ft. long, woody, much-branched; main prickles large, pungent, spreading; branches pale, ascending, zigzag. South Africa, 1816. (G. C. 1893, xxiii., p. 122, f. 46.)

A. lucidus (clear). *fl.* white, small, axillary. *fr.* pink, or white when ripe, ¼in. in diameter. *l.* narrow, flattened, falcate, 1in to 2in. long, disposed in fascicles of two to six. Stems thin, flexuous, 4ft. to 6ft. long, with small spines, branching freely. China and Japan. An elegant stove climber for pillars, &c.

A. medeoloides (Medeola-like). The correct name of *Myrsiphyllum asparagoides.*

A. plumosus (G. C. 1893, xxiii., p. 146, f. 58). SYN. *A. consanguineus.* The following are varieties:

A. p. albanensis (Albanian). *l.* longer and less numerous than in the type. 1895.

A. p. cristatus (crested). Branches less flattened, each terminating in a tassel-like cluster of branchlets and leaves.

A. p. declinatus (declinate). A variety with drooping branches.

A. p. Sanderi (Sander's). A curious seedling form, of tall habit, and having tufted, plumose growth on the large leaves. 1894.

Asparagus—*continued.*

A. p. tenuissimus (very slender).* This is of a lighter green than the typical *A. plumosus,* and the foliage is remarkable for its extreme slenderness and delicate appearance. South Africa, 1882.

A. retrofractus (bent back).* *fl.* white, small, axillary, umbellate. July. *fr.* small, globose, one-seeded. *l.* densely clustered, subulate, curved, ascending, ¼in. to 1in. long, bright green, Larch-like. Stems 6ft. or more in length, slender, woody, terete, much-branched; main prickles small, pungent, uncinate; branches slender, very zigzag. South Africa, 1759. SYN. *A. r. arborescus.*

A. sarmentosus (sarmentose). *fl.* white, star-like, fragrant; racemes 1in. to 3in. long, spreading from the woody branches. August. *fr.* bright scarlet, pea-like. *l.* linear, rigid, mucronate, ¼in. to ¾in. long, solitary except at the tips of the branchlets, flat, bright green, with a distinct midrib. Stems woody, sub-erect or twining, with short, deflexed prickles; branchlets numerous, square, spreading or ascending. South Africa, 1810. Cool house. (G. C. 1893, xxiii., p. 179, f. 71.)

A. scandens deflexus (deflexed). *fl.* smaller than in the type. *l.* firmer, ¼in. to ½in. long. Branchlets very zigzag.

A. schoberioides (Schoberia-like). *fl.* small, sessile, produced on the lower half of the branches. *fr.* red, small, abundant. *l.* in clusters of three or four, ¼in. long, linear, falcate, deciduous. Stems about 1ft. high, thin, wiry, branched above. Japan. Of this hardy but not very ornamental species there are one or two varieties, one having longer stems.

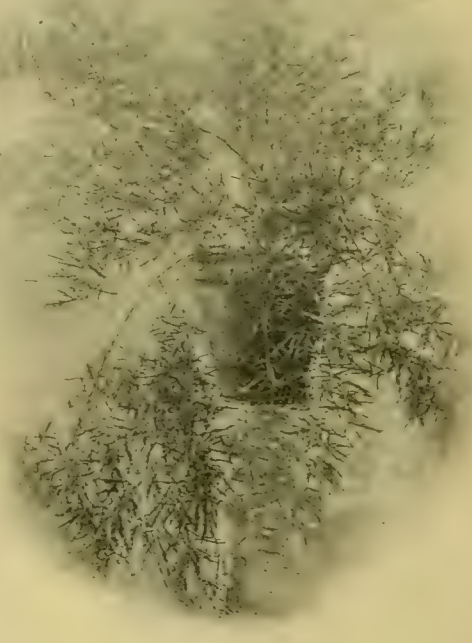

FIG. 82. ASPARAGUS SPRENGERI.

A. Sprengeri (Sprenger's).* *fl.* whitish, small, racemes 1in. long. *fr.* ⅛in. in diameter. *l.* flat, linear, glabrous, bright green, straight or slightly curved, 1in. to 1½in. long, ⅛in. broad, flattened, glossy green. Stems woody, terete, wide-climbing, 2ft. to 6ft. long, freely branched; prickles small, hooked. South Africa, 1890. A very elegant species. (R. G. 1890, p. 490, f. 80.) There is a variegated form. See Fig. 82.

A. tenuifolius (slender-leaved). *fl.* white, ¼in. across, axillary. May. *fr.* bright red, as large as Cherries. *l.* greyish-green, linear, curved, ½in. to 1in. long, in whorls of about a score at short intervals. Stems wiry, smooth, 3ft. high; branches ascending. France, Italy, &c., 1819. Half-hardy perennial.

A. tenuissimus (very slender). A variety of *A. plumosus.*

Asparagus—*continued.*

A. trichophyllus (hair-leaved). *fl.* axillary, usually solitary, on long pedicels. *fr.* pea-like. *l.* ¼in. to 1in. long, stiff, subulate, in clusters of twenty to thirty. Stems flexuous, 3ft. to 6ft. long, freely branched above; branches having curved-up spines at their base. Siberia and Northern China. Hardy perennial.

A. umbellatus (umbellate). *fl.* white, small, fragrant, in compact umbels of about a dozen. *fr.* pea-like. *l.* stiff, almost spinous, triquetrous, ¼in. long, in clusters of ten to twenty. Stems slender, striated, wiry, copiously branched above; branches drooping, thickly clothed with leaves. Canary Islands, 1823. A nearly hardy sub-shrub. SYN. *A. grandiflorus.*

A. verticillatus (whorled). *fl.* small. *fr.* bright red, like those of the common Asparagus. *l.* hair-like, ¼in. to 2in. long, in tufts of two to twenty. Stems ¼in. thick, woody with age, smooth, armed with short, hard spines at the nodes; branches numerous, slender, 1ft. to 2ft. long. Persia, Siberia, &c., 1752. Hardy.

ASPARAGUS BEETLE. This pest seems to be on the increase, and many cases are on record of entire failure of crops in certain districts owing to the prevalence of the Beetle. It has already been shown (Vol. I.) that the Beetle is sufficiently distinctive not to be passed over for any other. The larva, however, is not so readily recognised. It is of a bluish-grey colour, with black head and legs, and in length varies somewhat from ⅛in. or a little more to as much as ¼in. It feeds for some fourteen days, at the end of which time it assumes the pupal state beneath the soil. The Beetles deposit their eggs, which are frequently laid in rows, on the shoots and leaves of their food-plants, and though of comparatively small size they may readily be distinguished. The symptoms of attack of the Asparagus Beetle are a withering of the shoots, and instead of the plants presenting a light green appearance, patches of a brown or yellowish colour may be found upon them early in the season. Such plants, if examined, will almost invariably be found to harbour the larvæ of the Beetle under notice. These grubs, too, are difficult to dislodge, possessing as they do the power of holding on by means of the fleshy foot found at the anal extremity.

Besides the remedial measures suggested in Vol. I., it will be well to go over infested plants while the grubs are on the feed, and either squeeze them between finger and thumb, or remove them bodily and cast them into an insecticide previously prepared. Shoots, too, on which eggs have been deposited should be cut off and burned. It is useless removing such infested portions and then consigning them to the rubbish-heap.

ASPARAGUS RUST. *See* **Puccinia Asparagi.**

ASPASIA. The half-dozen species of this genus are all tropical American, ranging from Brazil as far as Central America. To those described on p. 124, Vol. I., the following should be added:

A. principissa (princely). *fl.* over 2in. across, somewhat resembling those of an Odontoglossum; segments light green, lined brown, lanceolate-linear; lip light buff, broadly pandurate, almost 1in. long, with two parallel tubercles at the base. Veraguas.

ASPERELLA (a diminutive of *asper*, rough; in allusion to the scabrous leaves). Also spelt *Asprella*. SYNS. *Gymnostichum*, *Hystrix*. ORD. *Gramineæ*. A monotypic genus. The species, *A. Hystrix*, is a rather tall, hardy, annual Grass, native of the Orient, with longer, looser, and slenderer terminal spikes than in *Elymus* (to which this genus is closely related), and flat leaves. It is largely used on the Continent in bouquets of everlastings, and for other purposes.

ASPERIFOLIÆ. Included under **Borragineæ** (which *see*).

ASPERULA. Of this genus about eighty species have been described; but not nearly that number are distinct as such. They extend over Europe, Asia (especially Western), and Australia.

A. azurea is the correct name of *A. orientalis.*

A. calabrica (Calabrian). A synonym of *Putoria calabrica.*

ASPHODEL, FALSE. *See* **Tofieldia.**

ASPHODEL, SCOTCH. *See* **Tofieldia palustris.**

ASPHODELINE. SYN. *Dorydium.* There are about fourteen species of this genus, natives of the Mediterranean region and the Orient as far as Persia and the Caucasus. To those described on pp. 124-5, Vol. I., the following should be added.

A. cretica (Cretan). A synonym of *A. tenuior.*

A. imperialis (imperial). *fl.* reddish-white, large. *fr.* angular. *l.* forming a magnificent rosette, somewhat prolonged up the stem, and not all springing from one base. Stem furnished with leaf-scales. *h.* 8ft. Thyana, Cappadocia, 1897. The largest of all the species. (G. C. 1897, xxii., p. 397, f. 116.)

ASPHODELOPSIS. A synonym of **Chlorophytum** (which *see*).

ASPHODELUS. The six or seven described species of this genus are reduced by Baker to five; they inhabit the Mediterranean region, one extending as far as India and the Mascarene Islands. To those described on p. 125, Vol. I., the following should be added. *See also* **Asphodeline.**

A. acaulis (stemless). *fl.* six to twenty in a lax corymb; perianth pale pink, 1in. to 1½in. long, funnel-shaped; peduncle very short or abortive. May. *l.* ten to twenty in a dense, radical rosette, linear, tapering to a point, 6in. to 12in. long, minutely pubescent. Algeria. (B. M. 7004.)

A. albus is a sub-species of *A. ramosus.*

A. comosus (tufted). *fl.*, perianth ⅝in. long, the segments white, with a green keel; panicle 1ft. long, with a dense, terminal raceme 2in. in diameter, and six or eight small side ones; peduncle stout, as long as the leaves. *l.*, radical ones ensiform, 1½ft. long, gradually tapering, acutely keeled at back. North-western Himalayas, 1837.

A. tenuifolius (slender-leaved). The correct name of *A. æstivus.*

ASPIDIOTUS. ORD. *Homoptera.* One of the numerous genera into which the scales are divided. It belongs to the group *Diaspina*, in which the scales are formed by the aid of the cast-skins and a kind of secretion. In this genus the scales are almost circular, while the exuviæ are central or lateral in the male, concealed, covered with a pellicle having a raised point in the centre. There is some little confusion existing with regard to the nomenclature of this genus, and the many synonyms which are from time to time employed add to the difficulty. Reference has already been made to the fact that *A. conchiformis* is no longer employed by naturalists for the Mussel Scale, but *Mytilaspis pomorum*, the former now being regarded as a useless synonym. The members of this genus are found on a variety of plants, both outdoors and under glass, and are most undesirable. The chief species found in gardens are referred to under **Scales** and **Pear Insects.**

ASPIDISTRA. SYNS. *Macrogyne* and *Porpax.* This genus embraces four species, natives of the Himalayas, China, and Japan. Leaves radical, long, ample, contracted into shortly-dilated petioles. To the species, &c., described on p. 125, Vol. I., the following should be added:

A. elatior (taller). The correct name of *A. lurida* (of gardens), described and figured in Vol. I.

A. punctata (B. R. 977) is synonymous with *A. clatior.*

A. typica (typical). *fl.* dirty white or greenish, speckled with red, dark purple within, numerous, radical, ¾in. in diameter, globose. September. *l.* 1ft. to 1½ft. long, long-petiolate, elliptic-lanceolate; nerves about seven. Rootstock stout, creeping. Tonkin (?), 1895. (B. M. 7434.)

ASPIDIUM. Buckler Fern. Including *Melanopteris* and *Phanerophlebia.* This cosmopolitan genus embraces about sixty species, showing remarkable variation as regards size, texture, cutting, and venation. To the information given on pp. 125-7, Vol. I., the following should be added. Several species formerly included here will now be found under **Nephrodium.**

Very few, if any, Aspidiums are fastidious in their habits. The exotic species found in the group *Polystichum* are particularly robust; and whether adapted to stove or to greenhouse treatment, all thrive in a mixture of three parts sandy peat and one part fibrous loam. They also succeed admirably in places where light is not

Aspidium—*continued.*

abundant, and where few other Ferns would hold their own.

The British portion of the group *Polystichum* is represented by the Prickly Shield Fern and its numerous varieties, all of which are free-growing, easily-managed, and very desirable for either the outdoor rockery, the indoor Fernery, or pot culture, as all are evergreen, delighting in a mixture of sandy loam and fibrous peat in equal parts, resting on a sound drainage. Although, when once established, the influence of strong light is not injurious to them, they produce much finer foliage when placed in a shady situation during the growing season. They require to be freely supplied with water at the roots: they must also be kept constantly moist during the winter. British Aspidiums are also excellent subjects for pot culture, as they bear indoor treatment much better than most native Ferns. Their propagation (except in cases of rare varieties, which are only increased by division of the crowns) is usually effected by means of spores; these are produced in great abundance, and if sown as they ripen, at the end of the summer, germinate rapidly, and make, during the following summer, young plants which are very valuable for the decoration of the greenhouse and of the conservatory during the ensuing winters.

The deservedly popular Ferns commonly known under the name of *Cyrtomium* are amongst the most useful of decorative plants, on account of their rapid growth and their firm, leathery texture, besides being all very distinct and particularly handsome. They are indeed the best Ferns to use in the least favoured places—in rooms and on staircases, where their fronds seem to defy draughts, smoke, and even gas, better than any other Ferns with which we are acquainted. Their bold and shining foliage forms a striking contrast to that of finer-cut species when planted out in the cool Fernery, under which treatment they develop into handsome specimens in an incredibly short time, and show themselves to great advantage. For that special purpose, Aspidiums of the *Cyrtomium* group are of the greatest value, as by the use of them additional charm may be given to the rockery not heated artificially, but simply protected by glass, where they, being of an evergreen nature, retain their beauty during the whole of the winter months.

The soil which suits Aspidiums best is a compost of about equal parts fibrous loam, peat, and silver-sand; but care must be taken that they are not potted hard, or, if planted out in the Fernery, that the soil round them is kept moderately loose. They require an abundant supply of water at the roots during the growing season, and frequent syringings overhead are beneficial during that time, but they should be watered sparingly during winter. The propagation of plants of this section, like that of most other Aspidiums, is best effected by means of spores, which are abundantly produced, and which germinate very freely if sown as soon as gathered.

Amongst Aspidiums the Holly Fern (*A. Lonchitis*) is somewhat capricious under cultivation, although when established it will thrive in the greenhouse and luxuriate for a time in stove temperature. The best mode of treatment, however, is that advocated by Mr. W. Reeve. He has grown it most successfully in the cool house, where it was constantly shaded and standing upon a cool, damp bottom. He employed a compost of sandy loam and peat in equal parts, with a liberal admixture of sharp sand. It may be cultivated upon the outdoor rockery, but great care is necessary, as it is a very shy plant to establish itself in dry, exposed situations. Mr. Reeve remarks that "a shady part of the rockery must be selected, where it can be kept constantly damp without ever being wet," and that it will not stand stagnant moisture; also that it must be planted firmly in the above-mentioned compost as early in the spring as possible, and that if a hand- or bell-glass can be kept over it for a short time it is all the better, as this will maintain the soil moist about it for some time without the application of much water, after which it should be gradually inured to more air. It is usually increased by means of its spores, which should be sown as soon as ripe, for the division of its crowns, when several are produced, is at all times, and even under the most favourable conditions, considered a very risky operation.

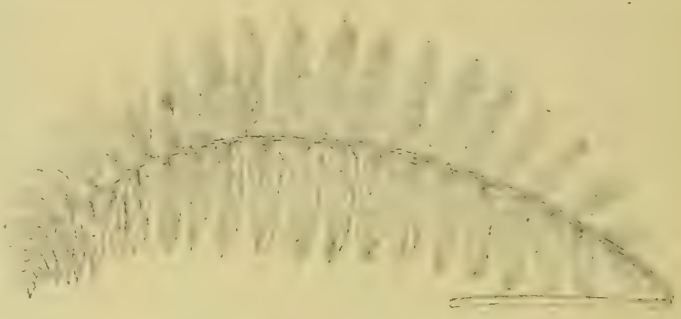

FIG. 83. FROND OF ASPIDIUM ACROSTICHOIDES.

Though perfectly hardy in most parts of this country, *A. acrostichoides* proves most useful when grown all the year round in either the cold house or the conservatory. Its handsome fronds, being of good substance, are very useful for cutting, and are admirably adapted for mixing with flowers. It is a species which thrives best in sandy peat and leaf-mould, with an abundance of water at the roots all the year round.

A. acrostichoides.* Christmas Fern. In North America the fronds (see Fig. 83) of this species are largely used for Christmas decoration.

A. aculeatum acrocladon (branched at apex).* *fronds* 1½ft. long, rich green, narrow, the pinnæ in the lower portion again divided to the midrib; apex of the fronds three-branched and repeatedly forked. An exquisite variety.

A. a. lobatum (lobed). A striking variety, chiefly distinguished from the type in its much shorter, more crowded, and less scaly pinnæ; the pinnules are also more nearly entire.

A. a. pulcherrimum (very pretty). *fronds* uncrested and quite barren; pinnules elongated and curved sickle-fashion, imparting a peculiar beauty to the frond.

Other more or less rare varieties are: *argutum, crassum, cristato-gracile, cristatum, densum, furcatum, interruptum, Moritzianum, multifidum, plumosum, pulchrum, setosum*, and *tsussimense*.

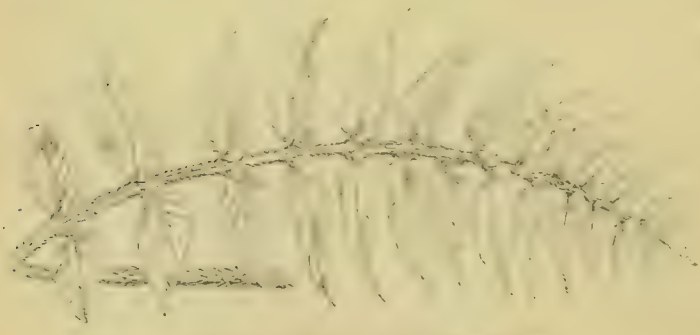

FIG. 84. FROND OF ASPIDIUM FALCATUM.

Aspidium—*continued.*

FIG. 85. ASPIDIUM FALCATUM PENDULUM.

A. angulare acrocladon (branched at apex). *fronds* about 10in. long, repeatedly branched at their extremity; rachis and under-side of the pinnules covered with light brown scales.

A. a. brachiatum (branched). *fronds* 1ft. to 2ft. long, pyramidal in form, the lowest pair of pinnæ being sometimes so large as to look like branches. The form *brachiato-cristatum* is a nearly allied form in which the end of each branch of the fronds terminates in a tuft.

Other varieties are: *acutilobum, acutum, alatum, aristatum, biserratum, cornutum, cristatum, Elworthii, Footii, grandidens, indivisum, interruptum, latipes, oxyphyllum, Padleyanum, præmorsum, pumilum, ramosissimum, setaceum, tripinnatum, truncatum,* and *varians.*

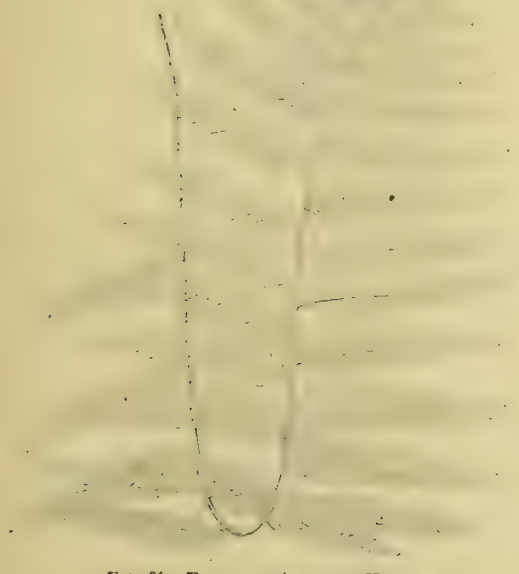

FIG. 86. FROND OF ASPIDIUM HOOKERI.

Aspidium—*continued.*

A. atratum (dark). A synonym of *Nephrodium hirtipes.*

A. Blumei (Blume's). A synonym of *Nephrodium intermedium.*

A. caryotideum (Caryota-like). A variety of *A. falcatum.*

A. concavum (concave). A synonym of *A. laserpitiifolium.*

A. coniifolium (Conium-leaved). A synonym of *A. aristatum.*

A. Fadyeni (Fadyen's). A synonym of *Fadyenia prolifera.*

A. falcatum. The bold fronds (see Fig. 84) of this species and its varieties make a striking contrast with those of the more finely-cut species when planted out in the cold Fernery.

A. f. Fensoni (Fenson's). *fronds* having pinnules broader than in the typical plant, and coalescing near the tips of the fronds. 1889. A robust form.

A. f. pendulum (pendulous). This differs from the type in its pendulous habit and in having narrower pinnæ. 1892. See Fig. 85.

A. Fortunei (Fortune's). A form of *A. falcatum.*

A. Hookeri (Hooker's). This evergreen species (a frond of which is shown in Fig. 86) has quite the habit of a Nephrodium, and is of similarly soft texture.

A. lobatum (lobed). A variety of *A. aculeatum.*

A. mucronatum. In habit, texture, and colour, this lovely dwarf, evergreen, easily-cultivated species somewhat resembles our native Holly Fern (*A. Lonchitis*). See Fig. 87.

FIG. 87. ASPIDIUM MUCRONATUM.

A. munitum.* This very handsome species, when well grown and fully developed, is one of the finest Ferns native of North America, where it is popularly known as Chamisso's Shield Fern. See Fig. 83.

A. Plumieri (Plumier's). A form of *A. trifoliatum.*

A. polyblepharum (many-fringed). A synonym of *A. angulare.*

A. proliferum (proliferous). A name applied to forms of *A. aculeatum* and *A. angulare.*

A. Richardi (Richard's). *sti.* stout, erect, 6in. to 12in. long, scaly throughout. *fronds* coriaceous, 9in. to 18in. long, 6in. to 9in. broad. *sori* in two rows midway between midrib and edge. New Zealand. This greenhouse species differs from *A. aculeatum* in its more rigid texture and shorter teeth, and in its lower pinnæ being of the same size as those in the centre of the frond. SYN. *Polystichum Richardi.*

Aspidium—*continued.*

FIG. 88. ASPIDIUM MUNITUM.

A. setosum (bristly).* *sti.* stiff, 8in. to 10in. long, very scaly. *fronds* evergreen, dark, 1½ft. to 1½ft. long, 4in. to 6in. broad; pinnæ densely placed; pinnules somewhat cordate, but terminating in a bristle, and so closely set as to overlap. *sori* scattered over the whole under-surface of the frond. Japan. A very popular and decorative, greenhouse or nearly hardy Fern. See Fig. 89. SYN. *Polystichum setosum.*

A. simulatum (simulating). A synonym of *Nephrodium simulatum.*

A. Standishii (Standish's). A synonym of *A. lasercpitiifolium.*

A. triangulare laxum (triangular, loose). *fronds* long and very narrow, somewhat drooping, of a leathery texture, and very lasting. A garden variety. SYN. *Polystichum xiphioides.*

A. triangulum ilicifolium (Holly-leaved). *sti.* slender, 1in. to 2in. long, clothed with large, light brown scales. *fronds* 6in.

FIG. 89. ASPIDIUM SETOSUM

Aspidium—*continued.*

to 9in. long, 1in. to 2in. broad; pinnæ about 1in. long, mucronate at apex, cut down below to the rachis into lanceolate lobes. *sori* principally in two rows near the midrib. Northern India. Greenhouse. See Fig. 90.

A. trifoliatum Plumieri (Plumier's). A large form, with more copious and more scattered sori, and a less distinctly peltate involucre than in the type.

A. tripteron. A frond of this characteristic species, which is almost hardy, but thrives in a greenhouse, is shown in Fig. 91.

A. truncatulum (slightly truncate). A synonym of *Didymochlæna lunulata.*

A. uliginosum (marsh-loving). A synonym of *Nephrodium cristatum uliginosum.*

A. vestitum (clothed). A variety of *A. aculeatum.*

ASPLENIUM. Including *Callipteris*, *Lötzea*, *Oxygonium*, *Thamnopteris*, and *Triblemma*. Nearly 350 species of this genus have been recorded, including plants from all parts of the world where Ferns grow.

Asplenium forms a most interesting genus among the Ferns of British origin, and are particularly useful on account of the evergreen nature of their fronds. The leathery texture of their foliage also greatly adds to their value as decorative plants; while the ease with which the strongest-growing kinds may be cultivated also tends to make these species particularly popular.

FIG. 90. ASPIDIUM TRIANGULUM ILICIFOLIUM.

Some of the very dwarf-growing sorts are somewhat difficult to preserve, especially in smoky localities, but these, besides succeeding fairly well in Fern-cases, are rendered specially attractive through their constitution and mode of growth, and they may safely be termed the gems among our native Ferns.

Most Aspleniums succeed best in a mixture of fibrous loam, peat, and sand, in equal proportions. In potting them, great care should be taken with the drainage, as, if it is at all defective the plants will soon become

Asplenium—*continued.*

flabby and otherwise begin to show symptoms of ill-health. With the exception of a few dwarf species, which grow naturally in walls or in fissures of rocks, Aspleniums, above all, dislike being potted hard. Many of them will stand the full rays of the sun under glass, but it is not beneficial in any way to the plants, which, instead of being of a healthy, bright, shining green colour, as nearly all of them are when in good condition, have a yellowish tint, although they may perhaps be hardier than those grown in partial shade.

Being native of countries very distant from one another, and being found wild under totally different conditions, it will be easily understood that Aspleniums require varied treatment, and, on that account, while some kinds really need stove temperature to develop their foliage to perfection, others do well in a greenhouse temperature, while a few of them may even be used with advantage for the ornamentation of the hardy Fernery. Although the majority of the hardier kinds—even our own *A. marinum*—grow very well for a time under the influence of strong artificial heat, it must be borne in mind that they are much more robust, although of slower growth, when kept in a lower temperature.

FIG. 91. FROND OF ASPIDIUM TRIPTERON.

A considerable number of exotic Aspleniums are either viviparous or at least proliferous at their apex. In either case if there is a desire to increase the stock of any particular viviparous or proliferous species, the portion of the fronds bearing the rudiments of young plants should be pegged down to the soil, and be kept moderately moist, when they will soon root.

When Aspleniums have to be produced in large quantities—such, for instance, as the kinds belonging to the *bulbiferum* group, which for decorative purposes are raised by the thousand—market growers find it more expeditious to detach the little bulbils when furnished with two or three tiny fronds, and to prick them in close together in shallow boxes filled with a loose compost of three parts peat or leaf-mould, one of loam, and one of sand: in this they produce roots very freely, and rapidly form young plants, which may be potted singly as soon as they have from six to eight fronds. None of the British Aspleniums are known to possess these viviparous or proliferous characters, and their propagation is usually effected by division of their crowns, although they may with advantage be increased from spores, which mostly ripen in the autumn and germinate freely during the following spring.

The genus *Asplenium* is unusually rich in decorative species and varieties, and comparatively few require special treatment. *A. Fabianum* is, however, one that

Asplenium—*continued.*

does. It succeeds when grown in peat and sand alone, and will be found to produce fronds of large dimensions, and especially bright as to colour. The Fern is admirably adapted for table-decoration, for vases, &c. It is perfectly evergreen, and very good-sized plants with a quantity of foliage may be grown in pots of comparatively small size.

Very decorative, too, is *A. caudatum*, an easily-grown Fern, requiring a mixture of peat and sand only. On account of the gracefully pendulous character of its fronds, this species is very well adapted for growing in hanging-baskets of large dimensions. The whole plant is of a beautiful dark, glossy green, which contrasts agreeably with the colour of the conspicuous fructification. The fronds, being of leathery texture, remain a long time on the plant. *A. formosum* is another species which must be grown in peat and sand, with the addition of a little crock-dust. Loam it does not like.

Noteworthy in connection with this genus is the fact that it contains several of our finest native Ferns, though unfortunately these are not as readily accommodated as are some of the exotics. One of the prettiest and most interesting of all such Ferns is *A. Ceterach*. It is not at all easy to cultivate successfully; it is too impatient of confinement to live long in a greenhouse, and the cold frame, so useful for the protection of other half-hardy species, is almost certain death to this. So wrote an experienced cultivator, Mr. Charles Johnson, more than a quarter of a century since. Further, he said that it universally seemed to prefer a calcareous habitat; and those who have seen it in a state of Nature can testify to that fact. Other points to be observed in its cultivation are ample drainage, whether in the open or in pots, and in the latter case it is, moreover, necessary to avoid wetting the fronds when watering.

Another native gem is the Black Maidenhair Spleenwort (*A. nigrum*), which, on account of the lasting qualities of its foliage, has taken a prominent position. Its dark, shining fronds, when cut and mixed with flowers, retain their freshness for an almost unlimited time; they are of elegant outline, and are produced in great abundance. It is found very plentifully in Cornwall, Devonshire, Somerset, Hampshire, and in some other counties, in shady places at the foot of trees and shrubs, as also along the hedges, in meadows, on old walls, and in disused quarries. These are the positions in which the fronds attain their greatest size, but the Fern will also bear continued exposure to sunshine, and when growing thus it is very dwarf and of a yellowish colour. It is also very useful for pot culture, as it thrives under glass in the cool house, even better than it does in the outdoor Fernery. The best soil for this Fern is a mixture of leaf-mould, sandy loam, lime rubbish, and fibrous peat in about equal parts. Propagation may be effected by means of spores, which are ripe about September; or by the divisions of the crowns during March and April.

Distinct and beautiful again is another native—the Lady Fern, one of the easiest grown and most decorative of all British Ferns. Mr. S. Moore thus writes of its requirements in "British Ferns": When placed about rockwork it should occupy a low, boggy situation at the base of the rock, being planted amongst turfy soil, kept thoroughly moistened, either naturally or artificially. It is far less beautiful if planted in dry, exposed situations. Few hardy plants which can be introduced among rockwork are so thoroughly lovely as a vigorous Lady Fern, placed just within the mouth of a cavernous recess large enough to admit of its development and just open enough that the light of day may gleam across the dark background sufficient to reveal the drooping, feathery fronds; and, what is more, it will delight to grow in such a situation

Asplenium—*continued.*

if freely supplied with moisture to its roots. In woodland walks, or on the shady margin of ornamental water, no Fern can be more appropriately introduced. When grown in a pot, it requires one of rather a large size, and should be planted in turfy soil intermixed with fragments of charcoal, sandstone, and potsherds. To attain anything like a fair degree of its ladylike gracefulness, this Fern must under all circumstances be well supplied with water.

Although really a British Fern, the Sea Spleenwort (*A. marinum*) does not not succeed well in the open in many parts of Great Britain; whereas it certainly luxuriates in warmth, and readily adapts itself to the treatment allowed even to our stove plants, it grows very well and forms splendid specimens in the cool and intermediate houses, pits, vineries, &c. It also proves one of the handsomest Ferns in cultivation when planted in the temperate Fernery. In its natural state the Sea Spleenwort appears to require very little nourishment for its maintenance, but when cultivated its young seedlings will often make their appearance and, if left undisturbed, grow luxuriantly in places where scarcely a particle of soil is to be found. It is, however, more satisfactory to plant it in a compost of three parts fibrous peat and one of sand, with thorough drainage.

Mention might now fittingly be made to the cultural requirements of the well-known Maidenhair Spleenwort (*Asplenium Trichomanes*), found almost everywhere in Britain. Hardy as the Fern is it prefers an exposed situation to a close or very shady one, in which the constant moisture, by collecting on the fronds, soon causes them to blacken and decay. If the plants are grown in pots, it is essential that these should be well drained, and frequent watering over the fronds must be avoided. The compost best suited for this species is a mixture of porous, loamy soil, lumps of sandstone, and old lime rubbish. In the hardy outdoor Fernery, *A. Trichomanes* is particularly adapted for the formation of a neat and pleasant edging where it can take its natural position; but in this case it should be planted between stones, and the crowns should be kept slightly above the surface of the soil. In such a position its graceful, slender fronds are shown to perfection. Propagated either by means of spores, which are generally ripe in August and germinate freely, or by the division of its crowns in March.

Two species which may be regarded as indispensable to any good collection of Ferns are *A. flabellifolium* and *A. flaccidum*. The former is best when grown in small hanging-baskets, as then its fronds are very graceful. In rustic cork baskets it is grown with most complete success, for it takes possession of the most ragged parts of them in a remarkably short time. Grown in pots or even trailing on the ground in a Fern-case, it has a weedy appearance. *A. fontanum* is another decided acquisition, as, on account of its dwarf, compact habit, it must be treated as an ordinary greenhouse Fern, have glass protection all the year round, and be shaded from the direct rays of the sun during the summer months. It is readily propagated by careful division of the plants during the spring months, when the portions thus obtained should be potted or planted in a mixture of sandy peat and broken bricks, or old mortar, or both; and particular attention should be paid to the drainage, which is best formed of freshly-broken bricks.

Greenhouse treatment should also be meted out to *A. lanceolatum*, another native Fern, though very local in its distribution. Like most of its congeners of small dimensions, it must be shaded from the hot sun. Under such treatment, and provided it be kept moderately moist, its fronds attain a length of from 10in. to 12in., and are of a beautiful dark green. A mixture of peat, lime-rubbish, bricks broken small, and leaf-mould, in about equal proportions, is what it likes. In planting or potting, the crown requires to be kept well above the surface of the soil. Usually propagated by division of the crowns in early spring, but the operation requires rather more attention than it is usual to bestow on British Ferns.

A. Goringianum pictum is another Fern which, though hardy in sheltered spots, is best grown in a greenhouse or under the shelter of a cold frame, using a compost of two parts of leaf-mould, one of fibrous loam, and one of silver-sand. Spores are produced in abundance, but the plant is propagated by division.

Although requiring stove heat to grow and develop their handsome fronds properly during the greater part of the year, *A. Nidus* and its varieties stand well out of doors in the summer if not exposed to the full sun, and they prove exceedingly effective when used in the subtropical garden. Great care must be taken to keep away slugs and woodlice, which are particularly fond of the young succulent fronds. These Ferns thrive best in a mixture of about equal parts rough, fibrous peat and chopped sphagnum. They require very little soil, most of the nourishment being derived from aërial roots, which are produced freely on the surface of the pot, and at the base of the fronds, if the atmosphere be kept in proper condition.

In *A. Selosii* and *A. septentrionale* we have two species somewhat difficult to manage. The former should be firmly potted between pieces of sandstone in loam, leaf-mould, rock-chippings, and sand, with good drainage. With the latter, as with all other species of delicate constitution and slow growth, it is necessary that the tufted crowns should be kept above the surface of the soil, and in potting it the essential point is to secure perfect drainage. A mixture of peat, loam, and old mortar, in about equal parts, should be used. Water must be sparingly given, taking care to avoid any superfluous moisture. The cold frame is the best place in which to keep the plant in good order.

It is worthy of special note that all Aspleniums are particularly free from the attacks of such pests as Thrips, Green-fly, and Mealy Bug, and are naturally clean plants, their worst enemies being Woodlice and Slugs, which are fond of their succulent stalks. The former must be trapped by means of slices of Carrot placed in their haunts, and the latter with bran or brewer's grains.

To the species and varieties described on pp. 127-35, Vol. I., the following should be added:

A. achilleæfolium (Achillea-leaved). *fronds* about 2ft. long, including the grey stipes, somewhat lanceolate; pinnæ numerous, soft, 4in. to 6in. long, 1in. broad, cut throughout to the winged midrib into numerous bluntly-toothed pinnules ¼in. long and ⅛in. broad. *sori* oblong, usually

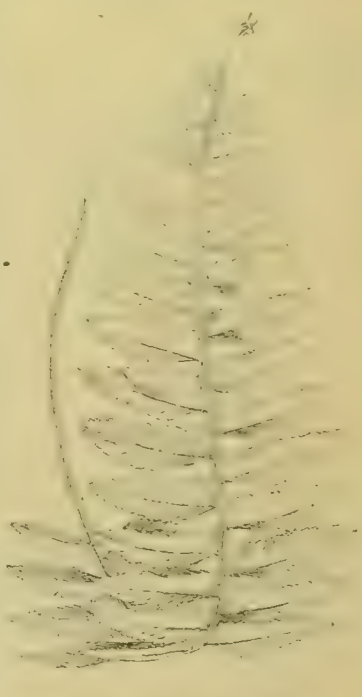

FIG. 92. FROND OF ASPLENIUM ALATUM.

Asplenium—*continued.*

one to each lobe of the pinnules. Mexico. Greenhouse. SYN. *Athyrium achilleæfolium.*

A. alatum. This species is readily distinguished by the broad and nearly transparent wings on the stipes and rachis. See Fig. 92.

A. amboinense (Amboyna). *rhiz.* creeping, clothed with black, subulate scales. *sti.* about 1in. long. *fronds* numerous, evergreen, lanceolate, narrowed below, truncate at apex, having a scaly bud at the end of the midrib, and a small, forked or multifid continuation of the frond. South Sea Islands, 1887. Stove.

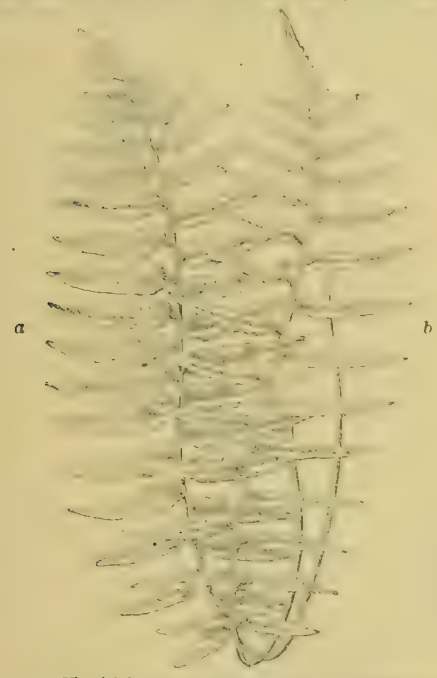

FIG. 93. (*a*) BARREN AND (*b*) FERTILE FRONDS OF ASPLENIUM ANGUSTIFOLIUM.

A. angustifolium. In damp, rich woods, especially in mountainous districts, this species is found in perfection. A barren and a fertile frond are shown in Fig. 93.

FIG. 94. ASPLENIUM ATTENUATUM.

Asplenium—*continued.*

A. attenuatum. The proliferous character of this singular, dwarf, rigid Fern, native of New South Wales and Queensland, is well shown in Fig. 94.

FIG. 95. ASPLENIUM BELANGERI.

A. auritum. The form *macilentum* has the rachis broadly winged and the pinnæ blunt; and *rigidum* has the pinnæ deeply pinnatifid throughout.

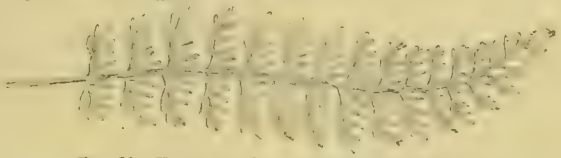

FIG. 96. FROND OF ASPLENIUM BRACHYPTERON.

A. axillare (axillary), of Aiton. A synonym of *A. umbrosum.*

A. bantamense (Bantam). *sti.* 6in. to 12in. long, firm, erect, nearly naked. *fronds* 9in. to 18in. long, with a large terminal

FIG 97. PARTIALLY-DEVELOPED BARREN FROND OF ASPLENIUM CAUDATUM.

Asplenium—*continued.*

pinna and one to four pairs of lateral ones, which are 6in. to 8in. long, 1¼in. to 2in. broad, narrowed at both ends, and with edges nearly entire. *sori* slender, irregular, nearly touching both edge and midrib. Himalayas, Hong Kong, &c. Greenhouse. SYNS. *A. fraxinifolium, Diplazium bantamense.*

A. Baptistii Drucryi (Druery's). A variety with broader pinnæ than in the type, and conspicuously crested. 1894.

A. barbadense (Barbados). *rhiz.* small, erect. *fronds* pinnate, densely tufted, erect, spreading, nearly or quite stalkless, pale green, 2in. to 4in. long, ¼in. to ⅜in. broad, tapering both ways; pinnæ spreading, numerous, sessile, oblong, the lower margin obliquely cut away, the rest crenate-toothed. Barbados, 1894. A pretty little stove species.

A. Beddomei (Beddome's). A synonym of *A. crinicaule.*

A. Belangeri. This handsome and deservedly popular species is one of the most elegant plants of the genus, forming a graceful plume of finely-divided fronds, spreading on all sides. See Fig. 95.

A. biforme (of two forms). A garden synonym of *A. dimorphum.*

A. brachypteron. Although introduced many years ago, this interesting species (a frond of which is shown in Fig. 96) is not so widely grown as it deserves. It should not be kept too warm. The warm end of a greenhouse, or the cool end of a stove, suits it best.

A. Bradleyi (Bradley's). *sti.* 2in. to 3in. long, polished, nearly black. *fronds* abundant, variable, usually pinnate, but in fully-developed specimens often pinnatifid and even bipinnate, 5in. to 7in. long, oblong-lanceolate; pinnæ eight to twelve pairs, the lower ones largest, all short-stalked and toothed. *sori* short, sub-costular. North America. Greenhouse.

A. Campbelli (Campbell's). *rhiz.* small, erect, with a few pale brown scales in the centre. *sti.* tufted, erect, rather strong, 4in. to 6in. long. *fronds* erect, composed of one or two pairs of contiguous, spreading lateral pinnæ, and a slightly larger terminal one, which are lanceolate, acuminate, 3in. to 5in. long, 1¼in. broad, shortly decurrent on the rachis. British and Dutch Guiana, 1885. Stove.

A. caryotæfolium (Caryota-leaved). A synonym of *A. cuneatum.*

A. caudatum. The frond illustrated at Fig. 97 is only partially developed, and does not show the tail-like appendage to which this plant owes its specific name.

A. celtidifolium (Celtis-leaved). *sti.* strong, erect, 1ft. or more in length, brownish, paleaceous below. *fronds* 2ft. to 4ft. long; 9in. to 18in. broad, pinnatifid at apex, pinnate below; pinnæ numerous, the lower ones distinctly stalked, 6in. to 9in. long, 1½in. to 2in. broad, acuminate, sub-entire or slightly toothed or lobed. *sori* beginning at the midrib and falling short of the edge. Cuba, Brazil, &c. Stove. SYN. *Diplazium celtidifolium.*

A. Ceterach ramoso-cristatum (branch-crested). *fronds* 8in. or more in length including the stipes, branching, and much divided at their extremity and occasionally crested as well; pinnæ variable in size and form, divided nearly or quite to the midrib. Ireland. An extraordinary form.

FIG. 98. ASPLENIUM COLENSOI.

A. Colensoi. When fully developed, the fronds of this elegant species are literally studded all over with young plants, by which means it may be readily propagated. See Fig. 98.

A. compressum. This thick, fleshy-looking Fern is different in appearance from any other known Asplenium (a frond and a detached pinna are shown in Fig. 99). It is known in Continental gardens as *A. fœcundum.*

A. conchatum (shell-like). *sti.* stout, erect, 2ft. or more in length. *fronds* 3ft. to 4ft. long, 1ft. to 1½ft. broad; lower pinnæ lanceolate, 9in. to 12in. long, 2in. to 3in. broad; pinnules numerous, lanceolate, cut down to a winged rachis into linear-oblong, spreading segments. *sori* short, oblong, in two oblique rows near the midrib. West Indies. Stove. SYN. *Athyrium conchatum.*

A. cordifolium (cordate-fronded). *sti.* firm, erect, 6in. to 12in. long, scaly below. *fronds* coriaceous, of an extraordinary shape,

Asplenium—*continued.*

being entire, cordate at base, and long-acuminate at apex. *sori* extending from the midrib to the edge. Philippine and Malay Islands. Stove. SYN. *Anisogonium cordifolium.*

FIG. 99. FROND AND PINNA OF ASPLENIUM COMPRESSUM.

A. costale (costal). *sti.* 1ft. or more in length, tufted, stout, erect. *fronds* large, the apex pinnatifid, the lower part copiously pinnate; pinnæ often 1ft. long, 3in. broad, cut down half or

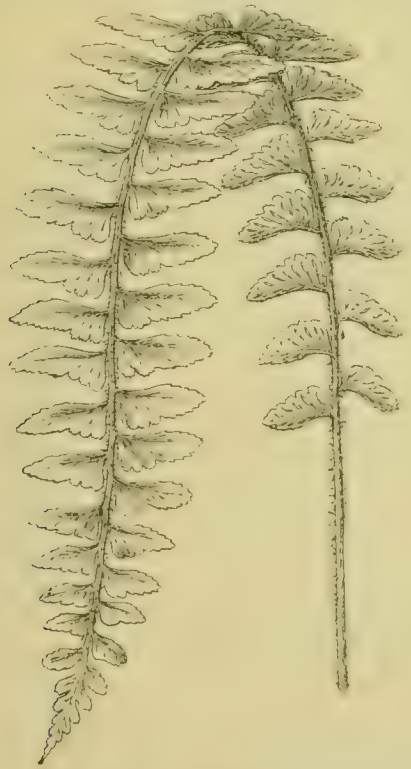

FIG. 100. FROND OF ASPLENIUM CRINICAULE.

Asplenium—*continued.*

two-thirds of the way to the rachis into blunt, slightly incised-serrated lobes. *sori* copious, broad, falling very short of the edge. West Indies to Peru. Stove. SYN. *Diplazium costale.*

A. crenulatum (slightly crenate). *cau.* erect. *sti.* firm, erect, 1in. to 1½in. long, hardly scaly below. *fronds* 2ft. to 3ft. long, 9in. to 15in. broad, pinnatifid at apex; pinnæ 6in. to 8in. long, 1¼in. broad, cut half or two-thirds of the way to the rachis into slightly-toothed, oblong lobes or segments. *sori* about ¼in. long, disposed close to the midvein of the fertile segments. Tropical America. A strong-growing, stove species, of nearly arborescent habit. SYN. *Diplazium crenulatum.*

FIG. 101. FROND OF ASPLENIUM DECUSSATUM.

A. crinicaule (hairy-stalked). *sti.* erect, 3in. to 4in. long, sparsely covered with dark brown hairs. *fronds* 6in. to 9in. long, 1½in. broad; pinnæ fifteen or more on each side, horizontal, subcoriaceous, obtuse, irregularly crenate on the edges, the upper side suddenly narrowed and sometimes auricled at base, the lower obliquely truncate. China, Sikkim, &c. Stove. See Fig. 100. SYN. *A. Beddomei.*

A. decurrens (decurrent). *sti.* short, grey, naked. *fronds* 1¼ft. to 1½ft. long, oblong-lanceolate; pinnæ five or six pairs, firm, parchment-like, dark green, proliferous at their extremity, adnate at their lower base, nearly or quite free and rounded on the

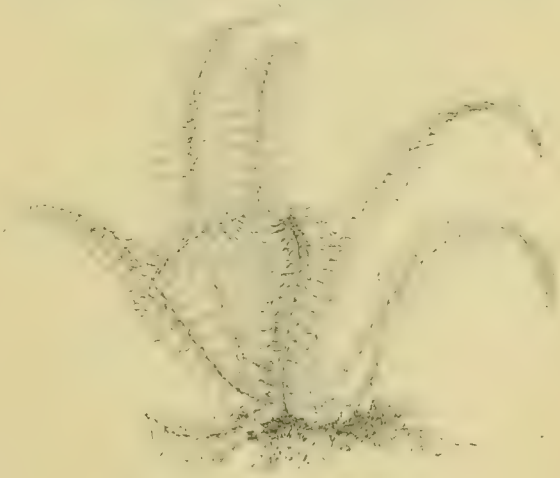

FIG. 102 ASPLENIUM EBENEUM.

Asplenium—*continued.*

FIG. 103. ASPLENIUM FERULACEUM.

upper side, crenulate above. *sori* in two parallel rows close to the midvein or rarely prolonged on either side of it. Samoa and Ceylon.

A. decussatum. A frond of this gigantic species is shown in Fig. 101.

FIG. 104. FROND OF ASPLENIUM FILIX-FŒMINA ACROCLADON.

Asplenium—*continued.*

A. dilatatum (stretched out). A synonym of *A. latifolium.*

A. divaricatum (divaricate). *sti.* very short. *fronds* 6in. long, 2in. broad; pinnæ numerous, closely set, almost overlapping, cut into numerous pinnules of a parchment-like texture not more than one line broad. *sori* solitary at the base of each pinnule. Chili and Peru. Stove.

FIG. 105. FROND OF ASPLENIUM FILIX-FŒMINA DISSECTUM.

A. Drueryi (Druery's). A form of *A. Baptistii.*

A. duale (double). *rhiz.* woody. *fronds* pinnate, 1½ft. long; pinnæ 1in. broad, serrated. *sori* linear, in two rows. Jamaica, 1893. A stove species, resembling *A. falcatum.*

A. ebeneum. The general appearance of this species, as will be gathered from Fig. 102, is that of an elongated form of *A. Trichomanes.*

A. elegantulum (rather elegant). A synonym of *A. incisum.*

A. elongatum (lengthened). A form of *A. tenerum.*

A. esculentum. The variety *serampurense* is a pubescent, simply-pinnate form.

A. ferulaceum (Ferula-like). *cau.* short, erect. *sti.* erect, naked, pale green, 6in. to 12in. long. *fronds* dark green, 1ft. to 2ft. long, somewhat ovate; pinnæ decreasing gradually upwards, the lowest horizontal or even deflexed, 6in. to 9in. long, 3in. to 5in. broad; pinnules subdivided into linear, flattened segments, which are again pinnatifid, the ultimate lobes being reduced to filiform organs ¼in. long. *sori* very small, lateral, abundant. Andes of Ecuador. This beautiful stove species is the most finely divided of the whole genus. See Fig. 103. SYN. *Darea ferulacea.*

A. Filix-fœmina acrocladon, a frond of which is shown in Fig. 104, is perhaps the most remarkably-crested form of the Lady Fern. Among other varieties the following call for mention:

A. F.-f. clarissima (very distinct). *fronds* 2ft. long, 1ft. broad, arching, very light green, and as finely divided as those of *plumosum.* Up to now this variety

FIG. 106. UPPER PORTION OF FROND OF ASPLENIUM FILIX-FŒMINA FIELDLÆ, with lower Portion showing arrangement of Pinnæ.

Asplenium—*continued.*

has failed to produce spores, and can only be propagated by embedding the edges of its pinnæ in light soil.

FIG. 107. FROND OF ASPLENIUM FILIX-FŒMINA GRANDICEPS.

A. F.-f. dissectum. The stipes and rachis of this variety are furnished with brown scales, which are so conspicuous as to impart the appearance of prickly processes. See Fig. 105.

FIG. 108. FROND OF ASPLENIUM FILIX-FŒMINA INCISUM.

A. F.-f. Fieldiæ (Miss Field's). *sti.* about 6in. long. *fronds* 2ft. or more in length, only 1in. broad, except just below the apex,

Asplenium—*continued.*

where they are 1½in. broad; pinnæ divided at base into two short pinnules, one part ascending, and the other descending, giving the fronds a cruciform appearance; near the apex the pinnæ merge into alternate pairs of gradually-diminishing, deeply-cut divisions, and the fronds terminate in a narrow, normal, truncate extremity. A remarkable form. See Fig. 106.

A. F.-f. Friselliæ coronare (crowned). A handsome variety, with short and much divided fronds. 1894.

A. F.-f. Girdlestonei cristatum (Girdlestone's crested). *fronds* of a pleasing green; pinnæ densely tufted. 1891. A slender, graceful form.

FIG. 109. FROND OF ASPLENIUM FILIX-FŒMINA VICTORIÆ.

A. F.-f. grandiceps. The weight of the dense, globose crest (Fig. 107) of this variety causes the fronds to assume a pretty arched appearance.

A. F.-f. incisum (cut). *fronds* gigantic, attaining 4ft. to 5ft. in length and 1ft. in breadth, broadly lanceolate, drooping; pinnæ tapering; pinnules often so deeply cut as to render the fronds almost tripinnate. See Fig. 108

A. F.-f. plumosum Dreweryi (Drewery's). A lovely plumose form. 1891.

A. F.-f. regale (regal). *fronds* very broad; pinnæ broad, prettily crested at the apex. 1889. A charming variety.

A. F.-f. setigerum grandiceps (bristle-bearing, large-headed). *fronds* erect, about 1ft. high, with a heavily-crested tuft at the apex; pinnæ divided and crested at the ends in an extraordinary manner. 1893.

A. F.-f. velutinum (velvety). A beautiful, dwarf, densely-branched variety, dwarfer than its parent *A. F.-f. acrocladon*, also closer and more compact in habit: this and the finely-divided apices give the plant the appearance of a ball of green velvet. 1892.

FIG. 110. FROND OF ASPLENIUM FLABELLIFOLIUM.

Asplenium—*continued.*

A. F.-f. Victoriæ. It is difficult to adequately describe the beauty of this "Queen of Lady Ferns," but Fig. 109 gives a good idea of the appearance of its fronds.

FIG. 111. ASPLENIUM FORMOSUM.

A. flabellifolium. Although not generally popular, this curious and pretty evergreen species is well worth growing in small baskets, or for covering the surface of the soil in small Fern-cases. See Fig. 110.

A. fœcundum (prolific). A popular name for *A. compressum.*

A. fœniculaceum (Fennel-like). A variety of *A. fragrans.*

FIG. 112. ASPLENIUM FRAGRANS FŒNICULACEUM.

Asplenium—*continued.*

A. formosum.* The lovely fronds of this elegant, delicate-looking, evergreen species are produced abundantly from a very short stem; and the wiry, polished nature of its dark stipes approaches the *A. Trichomanes* group. See Fig. 111.

A. fragrans fœniculaceum. The fronds of this charming garden variety are 10in. to 15in. long, including the stipes, and are only bipinnatifid. See Fig. 112.

FIG. 113. ASPLENIUM GERMANICUM.

A. fraxinifolium (Ash-leaved). A synonym of *A. bantamense.*

A. furcatum laceratum (torn). *fronds* broader, flatter, and more distinctly incised than in the type.

A. gemmiferum (bud-bearing). *fronds* of a more papery texture and generally proliferous at their extremities; otherwise closely resembling those of the popular *A. obtusatum. sori* copious, broad, falling short of both edge and midrib. South Africa, &c. Greenhouse.

A. germanicum. This species is allied to *A. Ruta-muraria.* See Fig. 113.

A. Griffithianum (Griffith's). *sti.* tufted, short, erect. *fronds* lanceolate, 6in. to 9in. long, ⅜in. to 1in. broad, acuminate, very gradually narrowed below, crenate-serrated, sub-coriaceous. *sori* reaching from the midrib two-thirds of the way to the edge. Assam and Sikkim. Greenhouse.

A. Harrisi (Harris's). *rhiz.* little larger than a pin's head. *sti.* tufted, thread-like, 1in. to 1½in. long. *fronds* pinnate, semi-erect or prostrate, 3in. to 5in. long, ¼in. to ½in. wide, attenuated into a naked, thread-like tail, proliferous at the end. *sori* medial, oblique. Jamaica (7000ft.); 1895. A fragile little, half-hardy species, allied to *A. viride.*

A. Hemionitis multifidum. The habit of this distinct variety, which has fronds quite as broad as they are long, is well shown in Fig. 114.

A. heterocarpum. A frond of this very distinct species is shown in Fig. 115. In habit the plant somewhat resembles a miniature Adiantum.

A. heterophlebium (variously veined). *sti.* 1ft. long, grey, scaly. *fronds* thinly herbaceous, 1ft. to 1½ft. long, 8in. to 9in. broad, with six to eight pairs of pinnæ below the pinnatifid apex; lowest pinnæ 2in. or more apart, 3in. to 4in. long, 1in. to 1½in. broad, acute, cordate at base, dark green, the edges undulated, naked; rachis villous; veins pinnate. *sori* not reaching the edge. Eastern Himalayas. SYN. *Anisogonium heterophlebium.*

A. hians (gaping). *sti.* 1ft. to 1½ft. long, slightly scaly. *fronds* 3ft. to 4ft. long, 2ft. to 3ft. broad; pinnæ thin, papery, dark green, the lower ones 1ft. or more in length and 4in. to 6in. broad; pinnules numerous, lanceolate, with blunt lobes reaching nearly to the rachis. *sori* short, oblong, only the lower ones being double. West Indies and Ecuador. An almost arborescent, stove species. SYN. *Diplazium hians*

Asplenium—*continued.*

FIG. 114. ASPLENIUM HEMIONITIS MULTIFIDUM.

A. horridum (horrid). *sti.* strong, erect, brownish, fibrillose. *fronds* 2ft. to 3ft. long, 8in. to 12in. broad; pinnæ numerous, spreading, 4in. to 6in. long, acuminate, lobed, cordate or broadly rounded at the base on the upper, truncate on a broad curve on the lower, side; rachis stout, fibrous. *sori* in two nearly parallel lines close to the midrib, a few also on the disk of the lobes. Sandwich Islands, Samoa, and Java, 1884. (H. S. F. iii. 193.)

FIG. 115. FROND OF ASPLENIUM HETEROCARPUM.

Asplenium—*continued.*

FIG. 116. ASPLENIUM INCISUM.

A. incisum. The habit of this Japanese and Chinese species somewhat resembles our British *A. lanceolatum.* See Fig. 116. SYN. *A. elegantulum.*

A. japonicum (Japanese). *rhiz.* slender, creeping. *sti.* straw-coloured. *fronds* 9in. to 15in. long, 4in. to 6in. broad; pinnæ eight to ten, papery, bright green, cut down in the lower part into close, oblong, slightly-toothed lobes. *sori* reaching two-thirds of the way to the edge on both margins. Japan, China, &c. Greenhouse. SYN. *Diplazium japonicum.*

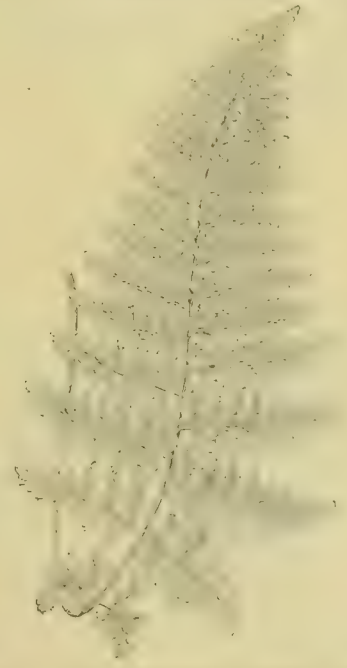

FIG. 117 FROND OF ASPLENIUM LANCEOLATUM.

Asplenium—*continued.*

A. Klotzschii (Klotzschy's). *sti.* strong, upright, dark brown, scaly at base. *fronds* 3ft. to 5ft. long, 9in. to 18in. broad; pinnæ 6in. to 9in. long, 3in. to 4in. broad, deep green, papery; pinnules 2in. to 3in. long, divided into slightly-toothed lobes. Venezuela. Stove. SYN. *Diplazium Klotzschii.*

A. lanceolatum. The Spear-shaped Spleenwort, as this species is commonly called, although indigenous in countries extending from England to Greece, as well as in Algiers, Madeira, the Azores, &c., is nevertheless very local, being found in sheltered, well-drained, and yet moist situations. A frond is shown in Fig. 117.

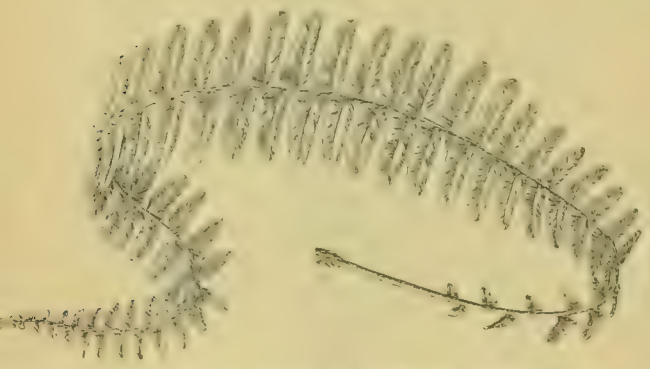

FIG. 118. FROND OF ASPLENIUM LONGISSIMUM.

A. lasiopteris (woolly Fern). A form of *A. Petersoni.*

A. latifolium (broad-fronded). *sti.* strong, erect, smooth, 1ft. or more in length, clothed at base with dark brown scales. *fronds* 3ft. to 4ft. long, 1ft. to 1½ft. broad; pinnæ about twelve on each side, the largest 1ft. long and 4in. broad; pinnules numerous, coriaceous, 2in. long, ½in. broad, and truncate at base, the edges slightly toothed. *sori* linear, about ¼in. long. Ceylon, &c. A greenhouse species, of almost arborescent habit. SYNS. *A dilatatum, Diplazium latifolium.*

A. Lechleri (Lechler's). *sti.* stout, upright, 2ft. to 3ft. long, scaly towards the base. *fronds* 3ft. long, 2ft. broad at the base; pinnæ very coriaceous, 1ft. long, 3in. broad, slightly toothed, tapering to a sharp point, rounded at base. *sori* beginning at the midrib, but falling short of the edge. Peru. A strong-growing, stove species, well adapted for the rockery. SYN. *Diplazium Lechleri.*

A. longissimum. Being an evergreen, this species is furnished at all seasons with its very elegant, pendulous fronds (Fig. 118).

A. lunulatum. There are a number of varieties, including *erectum, Fernandezianum, lobatum, pteropus, tenellum* (SYN. *reclinatum*), and *tripinnatifidum.*

A. Lyallii (Lyall's). A form of *A. obtusatum.*

FIG. 119. ASPLENIUM MARINUM.

Asplenium—*continued.*

A. macilentum (lank). A form of *A. auritum.*

A. marinum. The various situations in which this native species is found largely account for the number of forms observable. The typical plant is well shown in Fig. 119

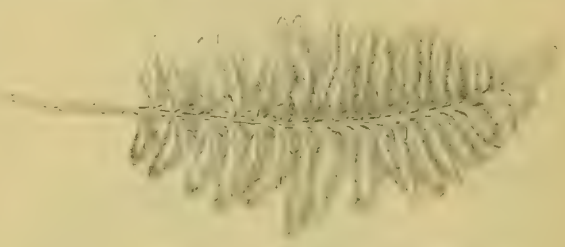

FIG. 120. FROND OF ASPLENIUM MARINUM IMBRICATUM.

A. m. imbricatum (overlapping). *fronds* having the pinnæ so closely placed that they overlap each other for fully one-half of their width; these are auricled at base and minutely dented on the margins. See Fig. 120.

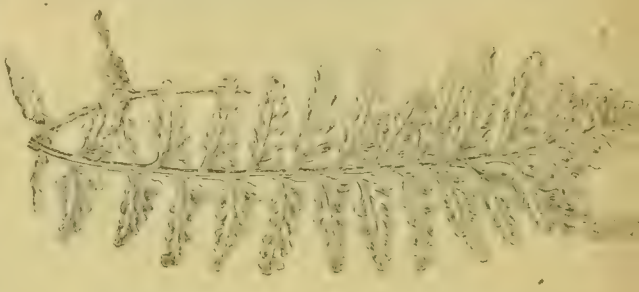

FIG. 121. FROND OF ASPLENIUM MARINUM RAMOSUM.

A. m. ramosum. The fronds of this variety, which are abundantly produced, are very irregularly divided, some being forked from the middle, and a few from the stalks, but most of them are branched near the apex only, as in Fig. 121.

A. Mayii (May's).* *fronds* dark purplish-green, short, gracefully arched, freely produced; pinnæ deeply notched. 1894. A seedling, of tufted habit, of which *A. Baptistii* is probably one of the parents. Stove.

FIG. 122. ASPLENIUM MONANTHEMUM, showing Habit and detached Basal Portion of Frond, with Bulbils.

Asplenium—*continued.*

A. monanthemum. The fronds of this species produce bulbils at the axils of the basal pair of pinnæ only, the plant being in this respect different from most other cultivated Aspleniums. See Fig. 122.

A. nigripes (black-footed). *sori* linear-oblong, often curved, disposed principally in two parallel rows close to the midrib of the pinnules. Otherwise this greenhouse species resembles *A. macrocarpum.* Japan, Nilghiris, &c. SYN. *Athyrium nigripes.*

A. nigro-paleaceum (dark-chaffy). *cau.* decumbent. *sti.* 1ft. to 1½ft. long, ¼in. thick, thicky clothed with nearly black scales. *fronds* thick, 2ft. to 3ft. long and nearly as broad; lower pinnæ 1ft. to 1½ft. long, 6in. to 8in. broad; pinnules numerous, spreading, 3in. to 4in. long, 1in. broad, cut down half or two-thirds to the rachis into incised-crenate lobes ¼in. broad; texture thick; rachis slightly zigzag. *sori*, lower ones ¼in. long. St. Helena. Greenhouse. SYN. *Diplazium Loddigesii.*

A. niponicum (Nipon). *rhiz.* creeping, with lanceolate, reddish scales. *sti.* 6in. to 12in. long, glossy, straminous. *fronds* herbaceous, 1ft. or more in length, 6in. to 8in. broad; pinnæ lanceolate, distinctly stalked, cut down nearly or quite to the rachis below into oblong-lanceolate, unequal-sided pinnules, which vary from sub-entire to deeply pinnatifid; rachis and both sides naked, often tinged with purple. *sori* copious, the lower ones often horseshoe-shaped. Japan and China. Greenhouse. SYN. *Athyrium niponicum.* There is a crested variety.

FIG. 123. FROND OF ASPLENIUM NITIDUM.

A. nitidum. This decorative species is found on the Nilghiri Mountains at an altitude of 4000ft. A frond is shown in Fig. 123.

A. nobile (noble). A variety of *A. viviparum.*

A. nodulosum (slightly noduled). A synonym of *A. lineatum.*

A. obliquum (oblique). A form of *A. obtusatum.*

A. obtusatum Lyallii (Lyall's). *fronds* herbaceous, nearly 1½ft. long, 9in. broad; lower pinnæ lanceolate-deltoid, 6in. long, cut down into deeply-toothed pinnules, which are cuneate at base and distinctly stalked.

A. o. obliquum (oblique). *fronds* cartilaginous, often more than 1ft. long and 6in. broad; pinnæ more numerous than in the type, often 4in. long and 1in. broad, gradually narrowed to an acute point. *sori* in lines ¼in. to ⅜in. long and closer.

A. obtusilobum. On account of its very peculiar mode of growth, this pretty, dwarf species is readily distinguished from all others. Instead of the proliferation being, as is usual in many Aspleniums, located at the extremity of the fronds, it consists in the slender, filiform growths which start from the base of the plant. See Fig. 124.

Asplenium—*continued.*

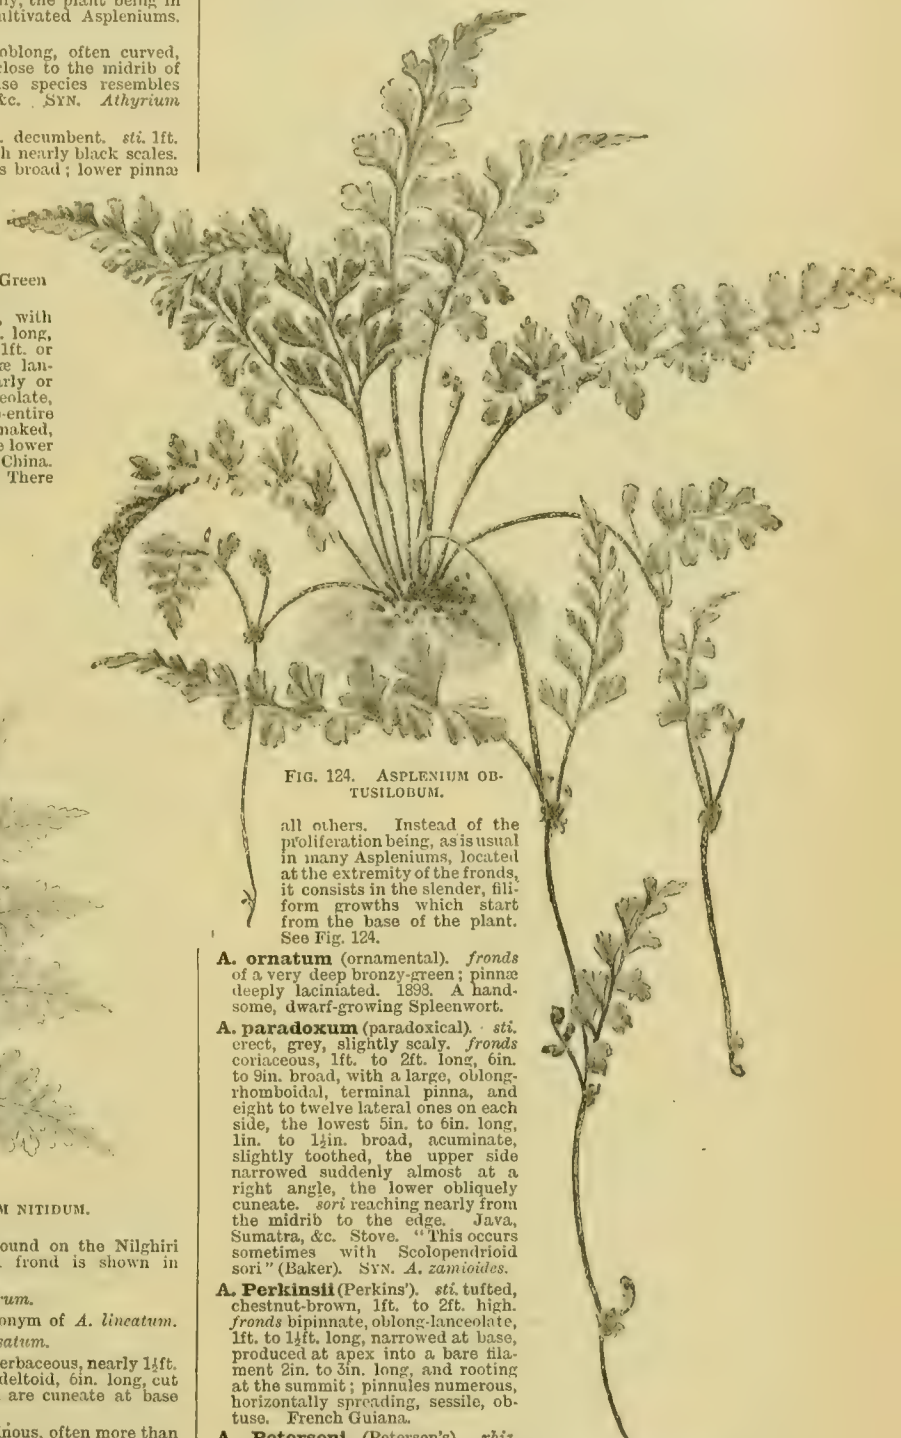

FIG. 124. ASPLENIUM OBTUSILOBUM.

A. ornatum (ornamental). *fronds* of a very deep bronzy-green; pinnæ deeply laciniated. 1893. A handsome, dwarf-growing Spleenwort.

A. paradoxum (paradoxical). *sti.* erect, grey, slightly scaly. *fronds* coriaceous, 1ft. to 2ft. long, 6in. to 9in. broad, with a large, oblong-rhomboidal, terminal pinna, and eight to twelve lateral ones on each side, the lowest 5in. to 6in. long, 1in. to 1½in. broad, acuminate, slightly toothed, the upper side narrowed suddenly almost at a right angle, the lower obliquely cuneate. *sori* reaching nearly from the midrib to the edge. Java, Sumatra, &c. Stove. "This occurs sometimes with Scolopendrioid sori" (Baker). SYN. *A. zamioides.*

A. Perkinsii (Perkins'). *sti.* tufted, chestnut-brown, 1ft. to 2ft. high. *fronds* bipinnate, oblong-lanceolate, 1ft. to 1½ft. long, narrowed at base, produced at apex into a bare filament 2in. to 3in. long, and rooting at the summit; pinnules numerous, horizontally spreading, sessile, obtuse. French Guiana.

A. Petersenii (Petersen's). *rhiz.* wide-creeping. *sti.* 6in. to 9in. long, erect, dark, villous. *fronds* 1¼ft. to 1½ft. long, 6in. to 8in. broad, with eight to ten pinnæ on each side below the pinnatifid apex; largest pinnæ 3in. to 4in. long, 1in. to 1¼in. broad, the lower lobes cut down nearly or quite to the rachis, ⅜in. to ½in.

Asplenium—*continued.*

deep, obtuse; texture herbaceous, the dark rachis and dark green fronds villous on both sides. *sori*, lower ones ¼in. long. Canton, &c. Stove. SYN. *Diplazium decussatum* (of gardens). *A. lasiopteris* is a form of this species.

A. pinnatifidum. This species bears a certain resemblance to the Walking Leaf of North America (*Scolopendrium rhizophyllum*), but rarely, if ever, roots at the apex of the fronds. See Fig. 125.

FIG. 125. ASPLENIUM PINNATIFIDUM.

A. polyodon (many-toothed). A synonym of *A. falcatum.*

A. polypodioides (Polypodium-like). *cau.* erect, nearly arborescent. *sti.* stout, green, 1ft. or more in length. *fronds* 4ft. long, 2ft. broad; pinnæ eight or nine on each side, 1ft. long, 6in. broad, thin, papery, bright green; pinnules numerous, cut into narrow-oblong, slightly-toothed lobes. *sori* distinctly falling short of the edge. Himalayas. Greenhouse. SYN. *Diplazium polypodioides.*

A. proliferum (proliferous). A synonym of *A. decussatum.*

A. pteridoides (Pteris-like). *sti.* 3in. to 4in. long, naked. *fronds* flaccid but firm, oblong-deltoid, 8in. to 9in. long, tripinnatifid, the rachis winged in the upper half; pinnæ close, the lower ones stalked, lanceolate-deltoid, 1½in. to 2in. broad, the lowest rather shorter and broader than the central ones; pinnules rhomboid, sessile, erecto-patent, pinnatifid in the upper half. *sori* on the outside of veins in the lobes only, ¼in. to ½in. long. Lord Howe's Island. Stove.

A. pteropus (wing-footed). A form of *A. lunulatum.*

FIG. 126. FROND OF ASPLENIUM RHIZOPHORUM.

Asplenium—*continued.*

A. pubescens (downy). A synonym of *A. esculentum.*

A. reclinatum (reclinate). A variety of *A. lunulatum.*

A. rhizophorum. This species varies greatly in the cutting of its fronds; it is best recognised by its elongated rachis bearing a solitary bulbil at the extremity. See Fig. 126.

FIG. 127. ASPLENIUM RUTÆFOLIUM.

A. rutæfolium. The habit of this beautiful species, which is a native, not only of South Africa, but also of the Himalayas, Ceylon, and Japan, is well shown in Fig. 127.

A. Ruta-muraria. Of this singular native Fern (see Fig. 123) there are several varieties, but owing to their small dimensions they are not very often seen.

FIG. 128. ASPLENIUM RUTA-MURARIA.

A. Sandersoni. The slender, proliferous-tipped fronds of this graceful species are shown in Fig. 129.

A. scandens (climbing). *sti.* scattered on a stout, creeping rhizome, very short. *fronds* 1ft. to 2ft. long, 6in. to 12in. broad, with numerous horizontal pinnæ on each side, which are 4in. to 6in. long, 1½in. broad, cut down to a distinctly winged rachis into numerous sub-distant, ovate-rhomboidal pinnules; pinnules cut down to the rachis throughout; lower segments again pinnatifid; ultimate divisions narrow-linear. *sori* solitary, marginal. New Guinea, &c., 1887. Stove. SYN. *Darea scandens.*

A. Schimperi (Schimper's). *rhiz.* wide-creeping, ½in. thick, with bright brown basal scales. *sti.* 3in. to 9in. long, naked. *fronds* firm, membranous, oblong-lanceolate or oblong-deltoid, 1ft. to 1½ft. long, 3in. to 9in. broad, tri- or quadripinnatifid; pinnæ close, lanceolate, stalked, the lowest distant, reduced; segments close, sharply incised-toothed. *sori* small, oblong-reniform. Abyssinia. SYN. *Athyrium Schimperi.*

A. semihastatum (half-hastate). *sti.* 6in. to 9in. long, slender. *fronds* herbaceous, 6in. to 9in. long, 3in. to 4in. broad, pinnatifid at apex, pinnate below; pinnæ mostly simple, oblong, auricled, the lowest stalked, 2in. long, 1in. broad, toothed, and cut nearly or quite to the rachis into spathulate pinnules. *sori* reaching from the midrib nearly to the edge. Cuba. Stove. SYN. *Diplazium semihastatum.*

A. septentrionale. The Forked Spleenwort, as this species is popularly called, is of a very cosmopolitan character, extending from India to the Rocky Mountains. The specific name doubtless refers to its being most frequently found in the Northern districts of Great Britain, where it is, however, very rare. See Fig. 130.

Asplenium—*continued.*

FIG. 129. ASPLENIUM SANDERSONI.

A. Serra (saw). *rhiz.* stout, creeping. *fronds* frequently 4ft. long and 1ft. broad, vivid green, elegantly arching; pinnæ fifteen to twenty pairs, spreading, 4in. to 8in. long, about 1in. broad, sharply toothed, rounded at base on the upper side, wedge-shaped on the lower side. *sori* prominent, disposed mostly in two parallel rows close to the midrib. Brazil, Peru, &c. Stove.

A. sinuatum (sinuate). *sti.* tufted, short, erect. *fronds* coriaceous, lanceolate, 1ft. to 2ft. long, 1in. to 2½in. broad, narrowed to an acuminate apex and very gradually below, the margin slightly undulated but not toothed. *sori* narrow, often on every vein, reaching from near the rachis nearly to the margin. Guinea Coast southward to Angola. Stove.

FIG. 130. ASPLENIUM SEPTENTRIONALE.

A. speciosum (showy). *rhiz.* wide-creeping. *sti.* erect, straw-coloured, 1ft. or more in length. *fronds* 1ft. to 2ft. long, 8in. to 12in. broad; pinnæ thin but firm, 4in. to 6in. long, ¾in. to 1in. broad, conspicuously lobed and slightly toothed, somewhat cuneate at base. *sori* slender, reaching nearly to the edge. Philippine and Malayan Islands. Stove. See Fig. 131. SYN. *Diplazium speciosum.*

A. squamulatum (slightly squamate). *sti.* tufted, 2in. to 4in. long, strong, erect, scaly below. *fronds* very coriaceous, lanceolate, 1ft. to 1½ft. long, 2in. to 3in. broad, narrowed to an acuminate apex and very gradually below into the stem, the margin entire; rachis stout, the lower part furfuraceous. *sori* reaching from near the midrib to within ¼in. or ½in. of the margin. Java, Borneo, &c. Stove.

A. striatum (striped). A synonym of *A. Shepherdi.*

A. tenellum (rather tender). A form of *A. lunulatum.*

A. tenerum (tender). *sti.* tufted, erect, naked, greyish, 4in. to 6in. long. *fronds* herbaceous, 8in. to 15in. long, 3in. to 4in. broad, oblong-lanceolate; pinnæ ten to twenty on each side, stalked, horizontal, 1in. to 1½in. long, ¼in. to ⅜in. broad, deeply toothed, unequal-sided, the lower ones deflexed. *sori* numerous, regular, parallel, not reaching either edge or midrib. Ceylon. Stove. *A. elongatum* is a form of this species.

A. thelypteroides. This species is found in the Sikkim Himalaya, up to 10,000ft. elevation, as well as in North America. The frond shown in Fig. 132 has the stipes rather shorter than is usually the case.

Asplenium—*continued.*

A. tomentosum (downy). *sti.* 6in. to 9in. long, erect, brown-tomentose, at length glossy. *fronds* 6in. to 12in. long, 3in. to 4in. broad, ovate-lanceolate; pinnæ numerous, closely placed, lanceolate, the lower pair deflexed, the next horizontal, 2in. to 3in. long, ¼in. broad, acute, the edge cut down regularly into oblong-falcate lobes ⅛in. broad; rachis finely tomentose. *sori* linear, touching the edge but not the midrib. East Indies, &c. Stove. SYN. *Diplazium tomentosum.*

A. unilaterale (one-sided). A synonym of *A. resectum.*

A. vagans (wandering). *sti.* tufted, 1in. to 2in. long, pale green. *fronds* coriaceous, 3in. to 4in. long, ¼in. to ⅜in. broad, widely straggling, elongated and rooting at the apex; pinnæ eight to twelve on each side, sessile, sub-rhomboidal. *sori*

FIG. 131. ENTIRE FROND AND DETACHED PINNA OF ASPLENIUM SPECIOSUM.

FIG. 132. FROND OF ASPLENIUM THELYPTEROIDES.

Asplenium—*continued.*

two or three to a pinna, placed near the margin. St. Thomas' Island, &c. Stove.

A. viviparum nobile (noble). *fronds* beautifully feathery, much more open and flat than in the type, 1½ft. long, quadripinnate; ultimate segments three times as long as those of the type, pendulous. *sori* abundant on the margins of the segments. New Guinea. Young plants are produced on the upper surface of the mature fronds.

A. zamioides (Zamia-like). A synonym of *A. paradoxum.*

ASPREGENIA. A synonym of **Octomeria** (which *see*).

ASPRELLA. *See* **Asperella.**

ASTELIA (from *a*, privative, and *stele*, a pillar; in allusion to some of the species living on trees, but not being parasitic). SYN. *Hamelinia.* ORD. *Liliaceæ.* A genus embracing about nine species of mostly greenhouse perennials, clothed with silky, shaggy, or chaff-like hairs, and with a short, thick rhizome, natives of New Zealand, the Pacific Islands, the mountains of Australia, Tasmania, and Antarctic America. Flowers white, greenish or purple, polygamo-dioecious, small, in dense racemes or panicles; perianth marcescent, persistent, six-parted. Leaves radical or crowded at the base of the scape, sheathing it. The species thrive in a compost of equal parts peat and loam, and may be propagated by divisions, in spring.

A. Banksii (Banks's). *fl.* greenish; perianth ¼in. in diameter; panicle densely silky, 4in. or more in length. *l.* 2ft. to 5ft. long, ¾in. to ⅝in. broad, glabrous or silky. New Zealand.

A. Cunninghamii (Cunningham's). *fl.* green, numerous; perianth rotate, ¼in. in diameter. *l.* 2ft. to 5ft. long, ¾in. to 1in. broad, spreading and recurved, plaited, silky, and villous. Scape 1in. to 1½ft. high. New Zealand. Probably half-hardy. (B. M. 5175.)

A. Solandri (Solander's). *fl.* greenish, very much crowded in panicles (male) 6in. to 18in. or (female) 8in. to 12in. long; perianth, male ¼in. long, female much smaller. *l.* 2ft. to 4ft. long, 3in. broad, spreading and recurved, clothed at base with dense, silky wool. Scape stout. New Zealand, 1864. (B. M. 5503.)

ASTELMA. Botanists include this genus under **Helipterum** (which *see*), the specific names remaining unchanged.

ASTER. SYN. *Pinardia.* Bentham and Hooker include the following genera (among many others) hereunder: *Bellidiastrum*, *Calimeris*, *Dieteria*, *Galatella*, *Linosyris*, *Machæranthera*, *Diplopappus*, and *Tripolium.* There are, according to those authorities, about 200 distinct species of this genus (nearly 350 have been described as such); they are most copious in the Northern hemisphere, particularly in America, where about 120 occur.

Of this extensive genus no section of it has been so much improved as that known as Michaelmas Daisies, Starworts, and Perennial Asters. The first name nowadays is, however, somewhat of an anachronism, seeing that many of the newer species and varieties blossom as early as July, and by a judicious selection it is possible to have bright and useful flowers for cutting onwards until winter arrives. The Perennial Asters of the present day are very different from the Michaelmas Daisies of old, many of which were poor and washed-out as to colour, and weedy and straggling as to habit. They are essentially flowers for the amateur, as they are not fastidious as to soil or surroundings, and may be grown in towns as well as in the country if but a little attention is bestowed upon them. They are far more useful, because more enduring and floriferous, than the usual tender occupants of beds and borders, which are allowed to drag out a miserable existence after the zenith of their beauty in late summer is passed, and they should be more extensively cultivated. A fillip was most certainly given to their culture after the Aster Conference of 1891, but they are still far from being sufficiently recognised considering their decorative qualities and their value as cut-flowers for vases and the like. For associating with many of the autumnal flowers—like the Japanese Anemones, the Double Sunflowers, and the Marsh Ox-Eyes—they are excellent, and last, too, whether cut or on the bush, a long time. For pot culture the Perennial Asters are now being much grown.

Aster—*continued.*

FIG 133. ASTER CORDIFOLIUS ELEGANS.

A well-worked, rich soil suits them admirably, and beyond a stout stake to prevent the tall-growing kinds from being broken by the strong winds and heavy rains of autumn, they require very little after-treatment. To see them to the best advantage a good wide border is necessary, allowing the plants ample room to develop, and especially the vigorous kinds. The tall varieties may then be accommodated in the back row, medium growers more towards the centre, and the dwarf varieties may be utilised for the edgings or even for rockeries, as many of them seldom attain more than 6in. in height. Such are *A. alpinus* and its varieties, the best of which are *speciosus* and *superbus.*

Perennial Asters are readily propagated by division in autumn or in spring. The latter, however, is the better season. It will also be found a good plan to discard the old stools—at least, of the strong-growing kinds—every second year, using for replanting only the outside portions. If dry, hot weather should set in, mulching is most beneficial. These Asters, it must be remembered, take a lot out of the soil, and to get the best results liquid manure-water should be occasionally given. Overcrowding must be avoided. It will be found a good plan to cut down the vigorous kinds in July to within 6in.

In the early-flowering section are *A. acris* and its variety *dracunculoides*; *A. Amellus bessarabicus* and Riverslea; *A. cordifolius*; *A. lævis* and its varieties Apollo, Arcturus, and Psyche; *A. Maackii*; varieties of *A. Novæ-Belgii*, like *lævigatus*, Purity, Harpur Crewe, Daisy Hill, and Madonna; and *A. Shortii.* Later come varieties of *A. lævis*—*decorus*, *floribundus*, *formosissimus*, and Ariadne; the compact little *A. dumosus*; *A. cordifolius elegans* (Fig. 133) and *A. c. albulus*; *A. ericoides Clio*; *A. Lindleyanus nanus*; Coombe Fishacre; *A. Linosyris*; a veritable host of garden forms of *Novæ-Belgii* in Robert Parker, John Wood, Nancy, Autumn Glory, Daphne, Ella, Margaret Jarvis, and White Spray; several good varieties of *A. Novæ-Angliæ* in *præcox*, *roseus*, *ruber*, and W. Bowman; and the exquisitely graceful *A. vimineus* and its form Cassiope. This last is one of the gems of the whole collection. Still later are *A. Novæ-Angliæ pulchellus*; *A. grandiflorus*; *A. Tradescantii*; *A. ericoides*, another graceful species; *A. amethystinus*; *A. diffusus*

Aster—*continued.*

horizontalis; A. d. pendulus; and the well-known *A. turbinellus.*

To those described on pp. 136-9, Vol. I., the following should be added. Several plants formerly classed under *Aster* are now transferred to **Callistephus, Erigeron, Felicia, Heteropappus, Inula, Microglossa, Olearia,** and **Sericocarpus.**

A. abbreviatus (shortened). A synonym of *A. patulus.*

A. Alberti (Albert Regel's). *fl.-heads* pale purple, terminal, solitary, 1in. in diameter; involucral scales in four series; ray florets linear, spreading. *l.* scattered, linear, slender, acute. Stems ascending, branching. Turkestan, 1884. SYN. *Calimeris Alberti* (R. G. 1152, f. 2, e-g).

A. albescens (whitish). A synonym of *Microglossa albescens.*

A. alpinus speciosus (showy).* *fl.-heads* showy, about 3in. in diameter; ray florets purple; disk orange. *h.* 1½ft. 1883. A dwarf, free-flowering variety. (R. G. 1283, 1276, f. 1.)

A. amelloides (Amellus-like). A synonym of *A. Amellus bessarabicus.*

A. amethystinus (amethystine-violet). *fl.-heads* rather numerous, racemosely disposed, with squarrose or spreading tips to the well-imbricated bracts; ray florets amethystine violet or purple, ½in. long. October. *l.* not rigid; cauline ones small, all linear and entire, not at all or scarcely narrowed at the abrupt, closely sessile or partly amplexicaul base. *h.* 2ft. to 3ft. North America. Plant paniculately much branched. SYNS. *A. bostoniensis* and *A. pilosus* (of gardens).

A. amygdalinus. The correct name is *A. umbellatus.*

A. Bellidiastrum. The correct name of *Bellidiastrum Michelii.*

A. bicolor (two-coloured). *fl.-heads* numerous, disposed in long corymbs; ray florets pinkish-white, passing into pink, and eventually turning lilac; disk yellow, turning purple. August and September. A garden form.

A. bostoniensis (Boston). A garden synonym of *A. amethystinus.*

A. cæspitosus (tufted). This is a dwarf and very floriferous garden form of *A. Novæ-Belgii*, with small flower-heads and leaves. August and September. North America. (B. R. xix., 1571.)

A. Chapmani (Chapman's). *fl.-heads* violet, showy, about ½in. across; involucre imbricated in several ranks, the bracts acute or mucronate. *l.*, radical ones spathulate-linear, 5in. to 9in. long, including the long-attenuated base; cauline ones becoming subulate-filiform and erect. Stem simple and slender, 2ft. to 3ft. high, with a few one-headed branches at the summit. North America.

A. cordifolius elegans (elegant).* A charming variety, producing its delicately-tinted blossoms in dense, plume-like masses. DIANA is a beautiful form of this.

A. coriaceus (leathery). A synonym of *Celmisia coriacea.*

A. coronopifolius (Coronopus-leaved). A synonym of *A. tanacetifolius.*

A. Curtisii (Curtis's). *fl.-heads* bright lilac, large, paniculate; involucre hemispherical, the much-imbricated bracts conspicuously appendaged with foliaceous tips. *l.*, radical and lower ones 3in. to 4in. long, ovate-lanceolate, acuminate, sparingly serrated, abruptly contracted into winged petioles; upper ones lanceolate, sessile. Stems 2ft. to 3ft. high. North America. A very showy plant.

A. Delavayi (Delavay's). This species is closely related to *A. Vilmorini*, but differs in having the disk of a permanent violet-brown instead of yellow shading off to brown. Yunnan, 1897.

A. diffusus horizontalis (horizontal).* *fl.-heads* having more conspicuous white ray florets than in the type. *l.* thickish; those of the widely-spreading flowering branches small and short, entire. A robust, very bushy and floriferous, garden variety. SYN. *A. horizontalis.* See Fig. 134.

A. diplostephioides (Diplostephium-like). Himalayan Aster. *fl.-heads* solitary, inclined, 2in. to 3in. in diameter; involucre broadly hemispherical, the bracts lanceolate; ray florets bright purple, numerous, biseriate; disk purple. May and June. *l.*, radical ones 2in. to 4in. long, obovate, varying to oblanceolate, acute, entire, narrowed to long or short petioles; cauline ones 2in. to 3in. long, sessile, semi-amplexicaul. Stem stout, 6in. to 18in. high, leafy. Sikkim, 1882. A glandular-pubescent, tomentose, or villous perennial. (B. M. 6718.)

A. foliosus is a variety of *A. vimineus.*

A. formosissimus (very beautiful).* *fl.-heads* disposed in a loose, pyramidal panicle; ray florets of a beautiful bluish-lilac; disk at first yellow, turning purple. September. *l.* alternate, ovate-lanceolate, acuminate, dark green; lower ones slightly crenulate. *h.* 1½ft. to 2ft. A garden form, of unknown origin.

A. gymnocephalus (naked-headed). *fl.-heads* rose-coloured, 1½in. in diameter. Summer and autumn. *l.* narrow-lanceolate, bristly-toothed. *h.* 1ft. to 1½ft. Southern Texas and Mexico, 1879. A pretty, half-hardy annual, of slender, bushy habit. (B. M. 6549.)

Aster—*continued.*

A. Herveyi (Hervey's). *fl.-heads* loosely corymbiform-cymose; ray florets bright lilac or violet, narrow, ½in. long; involucral bracts all erect. August and September. *l.* minutely serrated; radical and lower ones ovate, on naked petioles; upper ones lanceolate. *h.* 1ft. to 2ft. North America, 1839. (G. & F. 1839, p. 472, f. 131.)

A. hispidus (hispid). A synonym of *Heteropappus hispidus.*

A. horizontalis (horizontal). A form of *A. diffusus.*

A. incisus (cut). *fl.-heads* blue; ray florets ½in. long; involucral bracts reddish-margined. August and September. *l.* lanceolate, attenuated at both ends, remotely incised-serrated. Stem erect, striated, corymbose at apex. *h.* 1ft. to 2ft. Siberia, 1818. SYN. *Calimeris incisa.*

A. Lindleyanus (Lindley's).* *fl.-heads* disposed in loose panicles; ray florets pale violet, ½in. long; involucral bracts linear-attenuated. *l.*, radical and lower ones ovate, more or less cordate, on winged petioles; upper ones ovate- to oblong-lanceolate; uppermost ones sessile and acuminate at both ends. Stem 10in. to 20in. high, rather stout. North America, 1839. (G. & F. 1889, p. 448, f. 127.)

FIG. 134. ASTER DIFFUSUS HORIZONTALIS.

A. Linosyris (Linosyris).* Goldylocks. *fl.-heads* bright yellow, in a rather compact, terminal corymb, without any rays in this country, but occasionally rayed in Germany; involucre imbricated, with numerous narrow bracts. Late summer and autumn. *l.* numerous, narrow-linear, entire, more or less dotted. *h.* 6in. to 12in. Europe. SYNS. *Chrysocoma Linosyris, Linosyris vulgaris.*

A. longifolius roseus (pink). *fl.-heads* pink. A dwarf variety.

A. Maackii (Maack's). *fl.-heads* large, solitary at the apex of the stem or on the branches; ray florets bluish, more than twice as long as the involucre. August. *l.* scattered, lanceolate or narrow-lanceolate, acute or mucronate-acute, 1in. to 2½in. long, ¼in. to ½in. broad, entire or few-toothed, hairy on both sides. Stem 1½ft. to 2ft. high, one-headed or simply corymbose. Japan.

A. Novæ-Angliæ pulchellus (pretty). *fl.-heads* pale magenta. 1882. A very handsome variety, growing about 4ft. high.

A. pallens (pale). A synonym of *A. patulus.*

A. patulus (somewhat spreading). *fl.-heads* ½in. high, loosely paniculate; ray florets light violet or purple, varying to white. September. *l.* ovate- or oblong-lanceolate, sharply serrated in the middle, acuminate at both ends. *h.* 2ft. to 4ft. North America. SYNS. *A. abbreviatus, A. pallens* (B. R. 1509). There is also a dwarf, early-flowering form in cultivation.

A. pendulus (pendulous). A form of *A. diffusus*, with narrowish and less serrated leaves, verging towards or connected with *A. vimineus.* North America.

A. Piccoli (Father Piccoli's). *fl.-heads* having lilac ray florets and a yellow disk. *l.*, cauline ones sessile, oblong, coarsely toothed. Shen Si, China, 1899. (B. M. 7670.)

A. pilosus (pilose). A garden synonym of *A. amethystinus.*

A. polyphyllus (many-leaved).* *fl.-heads* ½in. high, paniculate; ray florets white, inclined to turn rosy-purple, numerous; involucral bracts linear-subulate. September. *l.*, cauline ones narrow-lanceolate or linear, 4in. to 5in. long, ¼in. to ½in. broad; those of the flowering branchlets small and subulate-linear. *h.* 3ft. North America.

A. pseudamellus (false Amellus). *fl.-heads* few, corymbose, 1in. to 1¾in. in diameter; ray florets bluish-purple; involucral bracts larger than in *A. Amellus*, with reflexed, leafy tips. Autumn. *l.* 1in. to 2in. long, oblong, acute or obtuse, entire or toothed. *h.* 6in. to 18in. Western Himalayas (8000ft. to 13,000ft.), 1836.

A. ptarmicoides (Ptarmica-like). *fl.-heads* several or numerous in a corymbiform head, small; ray florets white, ¼in. to ½in. long; involucre campanulate or somewhat turbinate, the bracts rigid. *l.* firm, linear or the lower ones spathulate-lanceolate. *h.* 6in. to 20in. North America. Plant varying from smooth or minutely scabrous to slightly hairy-pubescent.

A. punctatus (dotted). A synonym of *A. acris.* SYN. *Galatella punctata.*

A. repertus (a discovery). *fl.-heads* disposed in an ample panicle; ray florets reddish-pink; disk at first yellow or yellowish white, turning purple. September and October. *l.* alternate,

Aster—*continued.*

lanceolate, acute, slightly amplexicaul, bright green. *h.* 2ft. to 3ft. North America. A garden plant. There is a variety *cæruleus* with flowers of a bluish-lilac.

A. roseus (rosy). *fl.-heads* nearly 2in. across, disposed in a large corymb; ray florets of a beautiful bright rose; disk golden-yellow. *l.* lanceolate, sessile, pubescent, greyish-green. North America. Probably a variety of *A. Novæ-Angliæ*. (It. H. 1893, p. 103.)

A. rotundifolius (round-leaved). The correct name of *Agathæa cœlestis*.

A. Strachcyi (Strachey's). *fl.-heads* pale lilac-blue, ⅜in. to 1¼in. in diameter; involucral bracts reddish-brown; ray florets linear, the tips minutely notched; scapes rich dark brown, 2in. to 5in. high. May. *l.*, radical ones 1in. to 1½in. long, shortly petiolate, oblanceolate or obovate, pale beneath; those on the stolons much smaller and more sessile; those on the scapes few, linear or linear-obovate. Western Himalayas, 1885. (B. M. 6912.)

A. tanacetifolius (Tansy-leaved). *fl.-heads* ½in. high; ray florets bright violet, numerous; involucral bracts narrow-linear. July. *l.*, lower ones twice or thrice pinnately parted; uppermost ones simply pinnatifid or those on the flowering branchlets entire; lobes short, setulose-mucronate. *h.* 1ft. to 2ft. North America, 1851. A pubescent, often rather viscid annual. SYNS. *A. coronopifolius, Dieteria coronopifolia, Machæranthera tanacetifolia* (B. M. 4624).

A. tenuifolius (slender-leaved). *fl.-heads* about ½in. high; ray florets violet, showy; involucre turbinate, its bracts very acute. August. *l.* thickish, almost fleshy, linear, tapering to both ends, acute; lower ones with a long, tapering base; upper ones subulate-attenuated. Stem simple or paniculately branched above, 1ft. to 2ft. high. North America, 1725.

A. tenuifolius (of Willdenow). A synonym of *A. ericoides*.

A. Thomsoni (Thomson's). *fl.-heads* pale lilac, 1½in. to 2½in. in diameter, few, on long peduncles; involucral bracts linear-lanceolate; pappus reddish. August to October. *l.* sub-sessile, 2in. to 4in. long, 1in. to 1½in. broad, broadly-ovate, acuminate, coarsely serrated, half-amplexicaul at base. *h.* 1ft. to 3ft. Western Himalayas. Increased by seeds or cuttings; it should not be divided.

A. tricephalus (three-headed). *fl.-heads* one to three, large and showy; ray florets purple. Autumn. *l.*, radical ones obovate-spathulate, on long, winged petioles, entire, glabrous or hairy; cauline ones oblong, half-amplexicaul. Stems puberulous. *h.* 1½ft. Sikkim (10,000ft. to 14,000ft.), 1886.

A. trinervis (three-nerved).* *fl.-heads* blue; ray florets longer than those of the disk; involucral scales lanceolate; pedicels rigid. August. *l.* lanceolate-linear, mucronate-acute, entire, three-nerved, scabrous beneath and on the margins. Stems erect, corymbose at apex. *h.* 2ft. South of France, 1818. SYN. *Galatella rigida*.

A. trinervius (three-nerved). *fl.-heads* ½in. to ¾in. in diameter, corymbose; ray florets white, narrow; involucral bracts linear. Late autumn. *l.* sessile or petiolate, 1in. to 4in. long, lanceolate, coarsely serrated, very variable. *h.* 2ft. to 3ft. Himalayas, &c., 1891. (R. H. 1892, p. 396.)

A. umbellatus (umbelled). The correct name of *A. amygdalinus*.

A. Vilmorini (Vilmorin's). *fl.-heads* 4in. across, solitary or in pairs, at the top of a long, naked stalk; ray florets bluish-purple. *l.* 4in. to 6in. long, linear-lanceolate, acute, entire. Stems simple. *h.* 1ft. to 2½ft. Western China, 1896.

A. vimineus (twiggy).* *fl.-heads* very small, usually crowded along the branches; ray florets usually pure white; disk sometimes turning purple. September. *l.* linear or narrowly lanceolate, entire, or the lower ones with a few serratures, the longer cauline ones 3in. to 5in. long. Stem 3ft. to 5ft. high, slender, simple, with numerous flowering branches. North America, 1800.

A. v. foliolosus (rather leafy). The correct name of *A. foliosus*.

ASTER, WHITE-TOPPED. *See* **Sericocarpus.**

ASTERACANTHA. This in now included by Bentham and Hooker under **Hygrophila** (which *see*), and the correct name of *A. longifolia* is *H. spinosa*.

ASTERANTHEMUM. A synonym of **Smilacina** (which *see*).

ASTERIAS. A synonym of **Gentiana** (which *see*).

ASTERIDIA. A synonym of **Athrixia** (which *see*).

ASTERISCUS (of Mœnch). A synonym of **Odontospermum** (which *see*).

ASTERISCUS (of Schultz "Bipontinus"). A synonym of **Pallenis** (which *see*).

ASTEROMA VAGANS. *See* **Syringa Fungi.**

ASTEROPTERUS. A synonym of **Leyssera** (which *see*).

ASTEROSPERMA. A synonym of **Felicia** (which *see*).

ASTEROSTIGMA. Included under **Staurostigma** (which *see*).

ASTILBE. SYN. *Holcia*. There are about half-a-dozen species of this genus, natives of the Himalayas, Java, Japan, and Eastern North America. To those described on pp. 140-1, Vol. I., the following should be added:

A. chinensis (Chinese).* *fl.* white, with a rose or purplish tinge, densely clustered on rather short spikes. July. Stem branched. *h.* 1½ft. to 2ft. China, 1892. In habit this species resembles the well-known *A. japonica*, but the inflorescence is more loosely branched. SYN. *A. odontophylla*.

A. japonica foliis-purpureis (purple-leaved). An ornamental variety having purple leaves and stems. 1885.

A. j. variegata is known in gardens as *Spiræa reticulata*.

A. Lemoinei (Lemoine's). *fl.* pinkish-white, in very loose panicles. A garden hybrid between *A. Thunbergi* and a variety of *Spiræa astilboides*. 1895. (R. H. 1895, p. 567, f. 185.)

A. odontophylla (having toothed leaves). A synonym of *A. chinensis*.

ASTIRIA (from *a*, not, and *steiros*, sterile; in allusion to the absence of barren stamens). ORD. *Stereuliaceæ*. A monotypic genus. The species is a stove, evergreen, stellate-tomentose tree, thriving in a compost of sandy loam and peat. Propagated by cuttings, inserted in sand, under a bell-glass.

A. rosea (pink). *fl.* pink, disposed in axillary, pedunculate cymes; bracteoles three; calyx five-parted; staminal cup truncate, bearing at the apex twenty stamens, all fertile. May. *l.* large, entire, palmately nerved, deeply cordate. Bourbon, 1843. (B. R. 1844, t. 49.)

ASTRAGALUS. Upwards of 600 species have been referred to this genus, three of which are indigenous in Britain. To those described on pp. 141-2, Vol. I., the following should be added:

A. Gilgeanus (Gilge's). *fl.* deep violet. *l.* silvery. Asia Minor, 1896. Perennial.

A. hamosus (hooked). *fl.* pale yellow; calyx matted with hairs; heads six- to twenty-flowered, much shorter than the leaves. May to July. *fr.*, pods ¼in. to 1in. long, cylindrical, much recurved. *l.* 3in. to 6in. long; leaflets distinctly stalked. South Europe, &c., 1683. A curious-looking, trailing perennial. (S. F. G. 723.) The variety *macrocarpus* has large fruit.

ASTRANTHUS. Included under **Homalium** (which *see*).

ASTRANTIA. Four or five species, natives of Europe and Western Asia, are included in this genus. To those described on p. 142, Vol. I., the following should be added:

A. heterophylla (variable-leaved). A synonym of *A. helleborifolia*.

A. minor (lesser). *fl.* and involucre white, the leaves of the latter about equalling the umbel. May and June. *l.* palmate; segments seven to nine, lanceolate, acute, deeply and sharply toothed. *h.* 6in. to 9in. Europe, 1686. There is a variegated form of this.

ASTRAPÆA. This genus is now included under **Dombeya** (which *see*).

A. tiliæflora should be *A. tiliæfolia* (Lime-leaved), and its correct name is *Dombeya acutangula*.

A. viscosa. The correct name is *Dombeya cannabina*.

ASTROCARYUM. About thirty species, all natives of tropical America, have been enumerated. To those described on p. 142, Vol. I., the following should be added:

A. aculeatum (prickly). *fl.*, females sessile; calyx, as well as the rather longer corolla, densely prickly. *fr.* sub-globose, unarmed. *l.*, leaflets linear, præmorse. Stem tall. Guiana, &c.

A. Ayri (native name). *fl.*, spadices often many on the same stem, erect, nearly 2ft. long, simple, at first included in a fusiform, densely prickly spathe. *fr.* 1½in. long, obovate, rostrate, densely bristly. *l.* dense, 8ft. or more in length; leaflets narrow-lanceolate, long-acuminate, silvery beneath, 2ft. or more in length, 1in. broad. Stem 20ft. to 30ft. high, 10in. to 12in. thick. Rio de Janeiro, &c.

Astrocaryum—*continued.*

A. Borsignyanum (Borsigny's). A garden name for *Stevensonia grandifolia.*

A. Malybo (Malybo). The correct name of *A. argenteum.*

A. mexicanum (Mexican).* *fl.*, spathe shining chestnut-colour, terete, slightly prickly; spadix spicate. *fr.* sessile, fusiform, straight or slightly curved, rostrate, densely setose-prickly. *l.*, leaflets alternate, broadly linear, acute, straight; petioles tetragonal, channelled. Caudex cylindrical, 4ft. to 6ft. high. Mexico, 1864. (R. H. 1878, p. 148.)

A. pictum (painted). A garden name for *Stevensonia grandifolia.*

A. vulgare (common). *fl.*, spadix persistent, between the leaves; peduncle 1ft. or more in length, terete. *fr.* scarlet, ovate-globose, 1in. or more in length. *l.* eight or ten, rarely more, very slightly curved, 8ft. to 10ft. long; leaflets lanceolate, long-acuminate, white beneath. Stem 20ft. to 40ft. high, 3in. to 8in. thick, fuscous-greyish. Brazil.

ASTROLOMA. *See* also *Stenanthera. A. longiflorum* is the correct name of *S. ciliata.*

ASYSTASIA. SYN. *Henfreya.* Under this genus Bentham and Hooker include *Dicentranthera* and *Mackaya*, but the latter has been kept distinct on pp. 311-2, Vol. II., of this work. *Asystasia* embraces about a score species, natives of tropical and South Africa, the East Indies, and the Malayan Archipelago. Leaves membranous, entire. To the species described on pp. 142-3, Vol. I., the following should now be added:

A. bella (pretty). The correct name of *Mackaya bella.*

A. coromandeliana (B. M. 4248). The correct name is *A. violacea.*

A. macrophylla. This is figured as *Dicentranthera macrophylla* in B. M. 5696.

A. Thyrsacantha. According to the authors of the "Genera Plantarum," this is the correct name of *Thyrsacanthus indicus*; but C. B. Clarke, in Hooker's "Flora of British India" (iv. 497), classes it under *Eranthemum indicum.*

A. varia (varying). *fl.* mauve and brown, disposed in short, axillary racemes; corolla tubular. *l.* ovate or lanceolate. Stems quadrangular. *h.* less than 1ft. Zululand, 1892.

A. violacea (B. M. 5882). The correct name is *A. coromandeliana.*

ATALANTHUS. Included under **Sonchus** (which *see*).

ATALANTIA. SYN. *Chilocalyx* (of Turczaninow). Bentham and Hooker include *Severinia* under this genus.

ATELANDRA. Included under **Hemigenia** (which *see*).

ATHALIA SPINARUM. This is a species of Sawfly whose larvæ are very destructive to Turnips. They are whitish when first hatched, afterwards assume a dirty green colour, and eventually are black. It is this last colour which is responsible for the numerous popular names by which they are known to farmers and gardeners: Black Palmer, Black Canker, Black Slug, Blacks, and Niggers. *See* also **Turnip Sawfly.**

ATHALMUS. A synonym of **Pallenis** (which *see*).

ATHANASIA. About forty species, all strongly scented and glandular, are included in this genus. Flower-heads yellow, homogamous, discoid, usually rather small and densely corymbose; involucral bracts imbricated, in several rows. Leaves alternate, often crowded or small, entire, toothed, incised, or pinnatisect. To the species described on p. 143, Vol. I., the following should be added:

A. crithmifolia (Crithmum-leaved). *fl.-heads* numerous, in a compound corymb, sometimes paniculate. July. *l.* 1in. to 2½in. long, glabrous when adult, three- to five-cleft to the middle, rarely shortly three-cleft or entire; lobes linear, elongated. *h.* 2ft. to 3ft. 1723.

ATHEROPOGON. Included under **Bouteloua** (which *see*).

ATHLIANTHUS. A synonym of **Justicia** (which *see*).

ATHOUS. ORD. *Coleoptera.* Another of the genera furnishing the objectionable "Wireworms." The most destructive species is *A. hæmorrhoidalis*, an elongated downy brown Beetle, from ⅓in. to ½in. long, usually found

Athous—*continued.*

in the perfect state upon Hazels and Birches. The larvæ, however, when hatched, are very destructive to pastures and to cornfields. All the members of this genus are not, however, vegetarians; one species at least, and that a British one, is carnivorous, feeding upon several kinds of other Beetles. Unfortunately it is a rare insect, though occasionally found in decaying Ash and Beech. *See* **Wireworms.**

ATHRIXIA. SYN. *Asteridia.* This genus comprises about fifteen species of stove or greenhouse herbs or under-shrubs, natives of South and tropical Africa, Madagascar, and Australia. Flower-heads yellow, heterogamous, solitary at the tips of the branches or sometimes forming a loose, leafy corymb; receptacle flat, naked. Leaves alternate, entire, tomentose beneath.

ATHROTAXIS. To the species described on p. 143, Vol. I., the following should be added:

A. Gunneana (Gunn's). *l.* ⅛in. to ¼in. long, arranged spirally, spreading, slightly curved upwards, rigid, linear-lanceolate, widest at base, tapering to a spiny point, sessile; lower surface glossy-green, convex; upper surface flat or slightly concave, frequently covered with glaucous powder. Tasmania, 1869. A large, tolerably hardy bush, closely allied to *A. selaginoides.* (R. H. 1869, p. 114.)

ATHRUPHYLLUM. A synonym of **Myrsine** (which *see*).

ATIMETA. Included under **Rhodospatha** (which *see*).

ATRAGENE. Bentham and Hooker include this genus under **Clematis** (which *see*).

ATRAPHAXIS (the old Greek name given by Dioscorides, &c., to Orache). Including *Tragopyron.* ORD. *Polygonaceæ.* A genus embracing about seventeen closely-allied species of hardy, rigid, much-branched shrubs, natives of Central and Western Asia. Flowers often fascicled at the nodes, hermaphrodite, four- or five-parted, the two outer segments often smaller; stamens six to eight, rarely nine. Leaves alternate or fascicled at the nodes, narrow or rather small. The species here described are interesting plants. They should be grown in well-drained heath or sandy soil. Very little pruning will be required. Propagation may be effected by cuttings, or by layers.

A. buxifolia (Box-leaved). *fl.* white, nodding, produced in long racemes. July. *fr.* red. *l.* deciduous, obovate, obtuse, tipped with a short mucro, light green, about 1in. in diameter, the lateral margins undulated. *h.* 2ft. Siberia, 1800. SYNS. *Polygonum crispulum* (B. M. 1065), *Tragopyron buxifolium.*

A. lanceolata (lanceolate). *fl.* pink, in terminal, loose racemes, leafless above. *l.* lanceolate or oblong-lanceolate, acute or mucronulate, attenuated at base, penninerved, the margins recurved. *h.* 2ft. Russia, 1778.

A. l. latifolia (broad-leaved). A synonym of *A. Muschketowi.*

A. Muschketowi (Muschketow's). *fl.* white, about ¼in. broad, with red anthers and ovary; perianth five-parted, the two outer segments reflexed; raceme terminal, the flowers chiefly in whorls. May and June. *l.* 1in. to 1½in. long, oblong, acute, crenulate, shortly petiolate. Central Asia, 1895. (B. M. 7435.) SYN. *Tragopyrum lanceolatum latifolium* (R. G. 1894, t. 1344, f. 1-3).

A. spinosa (spiny). *fl.* white, tinged pink. August. *l.* glaucous, ¼in. long or less, ovate, acute, sub-evergreen, on short petioles. Branches ascending, horizontal, or deflexed. *h.* 2ft. to 3ft. Levant, 1732. (W. D. B. 119.)

ATRIPLEX. About 100 species of herbs and shrubs are included in this genus; they inhabit temperate and sub-tropical regions. Flowers monœcious or dicœcious, glomerate. The following species should be added to that given on p. 144, Vol. I.:

A. halimoides (Halimus-like). *fl.* white, all axillary, the males few in the upper axils, surrounded by females. *l.* ¼in. to 1in. long, mostly lanceolate or ovate-lanceolate, acute, on long petioles. Stems diffuse or procumbent, 6in. to 12in. or more in height. Australia. Plant softly mealy-tomentose. The variety *monumentalis* is a seedling form, growing 9ft. to 10ft. high. 1890. (R. G. 1890, p. 105, f. 24.) SYN. *A. nummularia monumentalis.*

A. Halimus (Halimus). *fl.* purplish, small. July and August. *l.* alternate or opposite, rhombic-oblong. *h.* 5ft. to 6ft.

Atriplex—*continued.*

Sea-coasts of South Europe, &c., 1640 A loose, rambling, hardy, sub-evergreen, glaucous shrub.

A. nummularia (money-like). *fl.* dicœcious, in dense spikes or panicles. *l.* mostly orbicular, rather thick, entire or scarcely sinuate-toothed, ¼in. to 1in. across, or on some luxuriant branches nearly 2in. Branches spreading. *h.* 9ft. to 10ft. Australia, 1890. Whole plant silvery-white tomentose.

A. n. monumentalis (monumental). A synonym of *A. halimoides.*

ATTALEA. About a score species, all tropical American, have been enumerated. To those described on p. 144, Vol. I., the following should be added:

A. excelsa (tall). *fl.*, spadix when fruiting 3ft. to 4ft. long. *fr.* oblong-sub-pentagonal, acute, about 5in. long. *l.* erecto-patent. Stem very tall (nearly 100ft.), erect, often 1½ft. or more in thickness Brazil.

A. speciosa (showy). *fr.* ovate-oblong, conico-rostrate. *l.* erecto-patent. Stem very tall.

Aubrietia—*continued.*

far in advance of those which the gardener of a century ago had at command. Besides the many desirable varieties of *A. deltoidea* there are some exquisitely beautiful garden forms, like Beauté de Bade, Fire King, Royal Purple, and Souvenir de Wm. Ingram.

To the species and varieties described on p. 145, Vol. I., the following should now be added:

A. deltoidea grandiflora (large-flowered). *See under* **A. d. Campbelli.**

A. d. Leichtlini (Leichtlin's).* A very ornamental form, with deep rose-coloured flowers. 1886.

A. d. Mooreana (Moore's). A tufted, compact variety, with blue flowers. *Campbelli* and *Columnæ* are nearly or quite identical with this.

A. d. olympica (Olympian) is a beautiful variety, having soft purple flowers.

A. superba (superb). A form of *A. deltoidea græca.*

FIG. 135. ALPINE AURICULA APOLLO.

FIG. 136. ALPINE AURICULA MELAINE.

A. spectabilis (remarkable). *fl.*, females ternate or quaternate on the branches of the spadix, which is 2ft. to 3ft. long. *fr.* ovate, fuscous-tomentose. *l.*, inner ones erect, outer ones erecto-patent, 18ft. long, with pectinate leaflets, of neat and showy habit. Stem 3ft. to 4ft. high, terete, nearly 1ft. thick, or almost wanting. Brazil.

AUBLETIA (of Gærtner). A synonym of **Sonneratia** (which *see*).

AUBLETIA (of Loureiro). A synonym of **Paliurus** (which *see*).

AUBLETIA (of Schreber). A synonym of **Apeiba** (which *see*).

AUBRIETIA. This genus consists of five species natives of Italy, Greece, Asia Minor, and Persia. Though Aubrietias are usually associated with the rock-garden, there is no reason why they should be so restricted as regards their use. They are equally beautiful when grown in a sunny border as edgings, or even in spring beds; while they may also be advantageously employed on sloping banks, and even upon walls. Aubrietias are old inhabitants of our gardens, but the kinds available now are

AUCUBA. Variegated Laurel. Three to five species, natives of the Eastern Himalayas, China, and Japan, are included in this genus. Flowers lurid purple, small, dicœcious, in axillary panicles; males having a small four-toothed calyx, valvate petals, four stamens, and a fleshy disk; females having the calyx-tube ovoid, the limb four-toothed, petals as in the males, and no rudiments of stamens. Leaves opposite, petiolate, ovate or lanceolate, obtusely serrated, coriaceous, shining, blackish when dry. In addition to the species described on p. 145, Vol. I., only the following variety calls for mention:

A. japonica fructu-albo (white-fruited). *fr.* pale greenish-white, much larger than in the variegated forms. *l.* wholly green, shining, stiff. 1893.

AUDIBERTIA (named in honour of M. Audibert, a celebrated nurseryman of Tarascon). ORD. *Labiatæ.* A genus comprising seven or eight species of nearly hardy, villous or cano-tomentose shrubs, confined to North America. Flowers scarlet, violet, or bluish, resembling those of *Salvia* (of the *S. officinalis* type); whorls often densely many-flowered. Leaves entire or crenate,

Audibertia—*continued.*

serrulated, reticulated. Only one species calls for description here. It thrives in any fairly good soil, and may be increased by seeds, or by cuttings.

A. incana (woolly). *fl.* pale blue; corolla less than 1in. long; bracts pubescent and ciliated, tinged with purple. Summer. *l.* spathulate or obovate, obtuse or retuse, entire or sparsely crenulate, seldom 1in. long. *h.* 1½ft. California, 1827. (B. R. 1469.)

AUDIBERTIA (in part). A synonym of **Mentha** (which *see*).

AUGEA (of Retzius). A synonym of **Lanaria** (which *see*).

AULACOPHYLLUM. Included under **Zamia** (which *see*).

AURELIANA. A synonym of *Bassova*. *See* **Witheringia.**

AURICLE. An ear-like appendage.

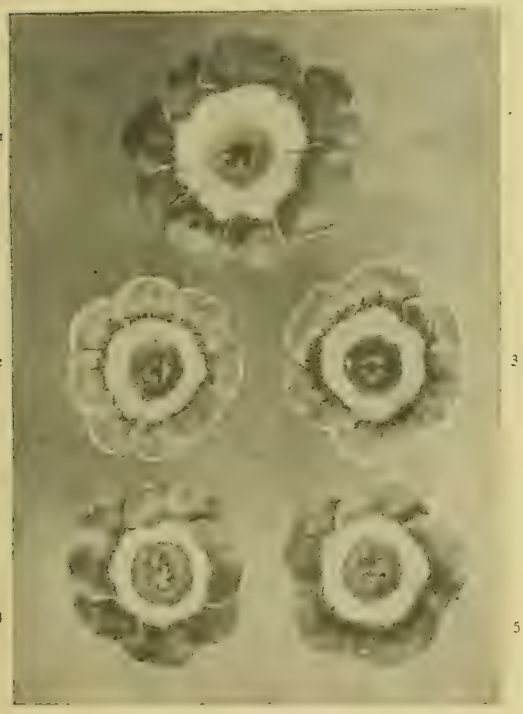

FIG. 137. SHOW AURICULAS: 1, Snitherfield Green; 2, Miss Prim; 3, Marmion; 4, George Lightbody; 5, Rev. F. D. Horner.

AURICULA. Since the issue of this work these charming spring flowers have taken quite a new lease of life, and alike for pots, the rockery, and the flower border, they are appreciated at their true worth. Few florists' flowers can boast such a time-honoured record as the Auricula, of which there is abundant evidence that it existed in gardens three centuries ago. Unfortunately the Show section (Fig. 137) is not suited for outdoor work unprotected, as the beautiful meal-like substance which characterises both flowers and foliage would be spoilt if the plants were exposed to heavy rains. Against the Alpines, however, no such objection can be urged, as they are destitute of farina, and there is, in fact, every reason why they should be found in collections of hardy spring flowers. Two promising varieties in this Section are illustrated at Figs. 135 and 136. Although many of the varieties which delighted our forefathers half a century or more

Auricula—*continued.*

ago—Champion for instance in the Green-edged, and Richard Headley in the Grey-edged—are still amongst the best in cultivation, the majority of those of even twenty years ago have been superseded, thanks to the skill of the florist. In making a selection of the newer kinds, only those likely to withstand the test of time have been included in each of the following sections:

Alpines.—DEAN HOLE (Douglas), truss large; corolla large, well formed, centre deep yellow; edge dark maroon, shading to crimson. DEFIANCE (Turner), good truss; corolla large, with cream centre; margin dark purple, shading to lilac-purple. DIADEM (Gorton), a good old variety of the creamy centre type, the margin shading from deep red to paler red. DUKE OF YORK (Douglas), handsome truss; corolla full-size, orange-yellow centre; margin maroon, shading to crimson. EDITH LODGE (Douglas), good truss; corolla large, yellow centre; margin yellowish-bronze. EVELYN PHILLIPS (Phillips), gold centre; margin deep red, shading to pale red. FRIENDSHIP (Douglas), good truss; finely-formed corolla, gold centre; margin dark red, shading to pale red. MRS. HARRY TURNER (Turner), a beautiful variety, with cream centre; margin maroon-purple, shading paler. MRS. MARTIN SMALL (Phillips), creamy-yellow centre; margin maroon-red, shading paler. MRS. PATRICK CAMPBELL (Douglas), vigorous plant, good truss; corolla large, centre clear yellow; margin buff, shading paler.

Green-edged.—ABBÉ LISZT, neat plant, truss well formed, tube deep yellow; paste white and dense, black ground; edge light green. JOHN GARRETT (Adams), tube pale yellow; good paste, dark ground, and full green edge. PRINCE OF GREENS (Trail), tube pale yellow; paste fine, good dark ground; edge superb green. REV. FRANCIS D. HORNER (Simonite), tube gold; paste white, black ground; edge fine green; corolla and truss large. SHIRLEY HIBBERD (Simonite), tube gold; paste white, black ground; edge fine green; a very fine variety SNITHERFIELD GREEN, a good variety, but comes slightly mealed sometimes. TALISMAN (Simonite), a very pretty variety, of fine quality; small plant and truss.

Grey-edged.—COLONEL CHAMPNEYS (Turner), good tube and paste, violet ground; edge light grey; a vigorous variety with slightly mealed foliage. GEORGE RUDD (Woodhead), clean yellow eye, black ground; edge distinct grey; mealed foliage. LANCASHIRE HERO (Lancashire), fine black ground; edge grey, inclining to green; green foliage, MABEL (Douglas), tube good; paste white, black ground; edge greenish-grey; a finely-proportioned flower. MARMION (Douglas), tube yellow; paste white, black ground; edge decided grey, well proportioned; foliage finely mealed. RICHARD HEADLEY (Lightbody), tube golden; paste dense white, quite black ground; edge silvery-grey; foliage green; a late variety. RINGLEADER (Kenyon), edge fine grey; foliage green; this is the reputed parent of GEORGE LIGHTBODY. SILVIA (Douglas), tube gold; paste good round and white, black ground; foliage green. WILLIAM BROCKBANK (Mellor), tube clear yellow; paste good white, bold black ground; decided grey edge; large truss of flowers.

Selfs.—BLACK BESS (Woodhead), tube orange; paste good white; edge blackish-maroon; foliage green. BUTTERCUP (Horner), tube rich yellow; paste white and circular; edge golden-yellow; foliage green. CHARLES J. PERRY (Turner), a good violet. HEROINE (Horner), tube rich orange; paste dense white and circular; edge dark maroon; bold green foliage. MRS. POTTS (Barlow), tube gold; paste pure white; violet margin; mealed foliage and fine truss. NEGRO (Mellor), tube and paste gold, maroon; foliage green. REV. CHARLES KINGSLEY (Douglas), tube gold; paste white; margin bright violet; foliage mealed. RUBY (Simonite), ruby red; the finest yet raised. SAPPHIRE (Horner), tube pale yellow; paste white; violet-blue edge; foliage mealed. SIR LANCELOT (Douglas), tube orange; edge reddish-maroon; foliage green. SIR WILLIAM HEWITT (Douglas), paste white and circular; a good dark self; foliage green. VULCAN (Sims), tube orange; paste white; margin black; foliage slightly mealed; very distinct.

White-edged.—DR. KIDD (Douglas), edge white and distinct; foliage finely mealed. HEATHER BELL (Simonite), tube pale yellow; paste good white, bluish ground, and edge well-defined. MISS PRIM (Douglas), tube yellow; paste dense white, violet ground; edge medium white; free-growing mealed foliage. MRS. DODWELL (Woodhead), tube yellow; paste white and dense, black ground; good white edge. PRINCESS MAY (Douglas), tube a good yellow; fine blackish ground; edge pure white; foliage green. RELIANCE (Mellor), tube yellow; paste good white, dark maroon ground; edge greyish-white; foliage slightly mealed. SNOWDON'S KNIGHT (Douglas), tube rich yellow; paste dense white, black ground; edge very white; foliage mealed.

Beyond the pests referred to in Vol. I. there is only one addition to make. This is the "rot" to which Auricula roots are subject. If, therefore, at the time of potting decay is noticed, such portions should be cut away and dry quicklime pressed firmly into the wound.

AUSTRALIAN FEATHER PALM. *See* **Ptychosperma.**

AUSTRALIAN HAREBELL. *See* **Wahlenbergia gracilis.**

AUSTRALIAN MINT BUSH. *See* **Prostanthera.**

AUSTRALIAN PEPPER-TREE. *See* **Schinus molle.**

AUSTRALIAN RED BERRY or **SEA BERRY.** *See* **Ragodia.**

AUSTRIAN ROSE. *See* **Rosa lutea.**

AUTUMN TINTS. With landscape gardeners in particular, there has been a growing disposition evinced to include in their trees and shrubs a due proportion of such as "take on" Autumn Tints. They make most effective colour-pictures at a very sombre time of the year, and the foliage alike on the trees and shrubs and when cut is extremely decorative. The idea is worthy of extension, and all gardens large enough to give place to hardy shrubs and trees should contain some of those remarkable for the effect of their foliage in autumn.

The uses to which Autumn-Tinted foliage may be put are numerous. It forms a good setting for cut-flowers for various purposes. Sprays of Thorns with fruit, or sprigs of the popular Guelder Rose crowned with its glowing berries, are strikingly beautiful for placing in vases for table-decoration; while for harvest festivals, and for indoor decorative purposes, Autumn-Tinted foliage is well adapted.

The various forms of *Acer palmatum*, or *A. polymorphum*, as it is frequently called, exhibit an almost endless variety of leaf-colour. A fine colour-picture could be obtained by planting them in groups on sloping mounds—preferably facing south or west, due regard being paid to habit of plant, form and colour of leaf—with a suitable background of green-leaved subjects. The result would be a perfect panorama of colour in October which would baffle even the skilled artist to reproduce. The stately Beeches and noble Elms are picturesque, and in spring, when the first-named are mantling themselves with leaves of the tenderest green, or in autumn, when the colour changes to shades of russet brown and yellow, few trees are more pleasing to the eye. The Amelanchiers Virginian Creepers, *Rhus Cotinus*, *Nyssa sylvatica*, and *Parrotia persica*, are, when arrayed in their autumn colours, unequalled, much less surpassed, by the showiest foliage plant of our stoves.

The most highly-coloured tints are given by deciduous subjects, and although we do not, as a rule, look to evergreens with a great degree of expectation, still, some of them assume pleasing shades from October onwards; in fact, not a few reveal considerable beauty during the winter months.

A few of the subjects falling under the designation above adopted rank amongst the showiest of flowering and ornamental foliage shrubs and trees—*Eucryphia pinnatifolia*, for instance, with lovely pure white flowers and golden-yellow anthers, can scarcely be known too well, as it blossoms towards the latter part of July and August, when the majority of shrubs have given of their best. Its glossy green leaves, composed of several leaflets, are heavily tinged with orange and brown in October.

The Thorns (*Cratægus*), again, in autumn, and particularly those of the North American representatives, are charming pictures in red, crimson, yellow, and gold. *C. Crus-galli* is an exceedingly beautiful tree, whose leaves, after assuming various shades of bronze-green, irregularly margined with red, eventually die off a rich crimson. The variety *prunifolia* is equally remarkable and quite distinct by reason of its purplish-brown, claret, and orange-shadings. *C. splendens*, *C. arbutifolia*, and *C. ovalifolia* belong to the same group, and are characterised by

Autumn Tints—*continued.*

the crimson and scarlet hues of the decaying foliage. *C. pinnatifida*, from Northern China, is conspicuous for its peculiarly bronze-tinted leaves set on red petioles. *C. coccinea* is a charming tree in the landscape in autumn; its leaves, blotched with purple, hang on the trees until late in the season. *C. monogyna ramulis-aureis*, whose leaves are clear yellow in spring and summer, and heavily tinted with orange in September; also *C. tomentosa* and *C. mollis*, are all desirable.

Liriodendron tulipifera (Tulip-tree) has leaves which are distinct from those of all other trees; they are four-lobed and of a pleasing shade of green, which in autumn changes to yellow and orange. The North American Witch Hazel (*Hamamelis virginica*) is of value in the garden in early winter, when its decaying foliage is suffused with yellow.

The genus *Ribes* contributes its quota of glowing colours. *R. aureum* (Buffalo Currant), which makes such a pretty picture in spring, when its drooping, slender racemes of yellow flowers are displayed so abundantly, is equally beautiful in October, when its smooth, green, much-cut leaves change to shades of rose-pink. The variety *aurantiacum* is even showier than the type, the bright-tinted foliage being very striking. *R. prostratum* is from a colour point of view worthy of a place in the rock garden. Its large leaves, of various shades of green, are tinted and edged with red, and before they fall are almost wholly crimson. Flowering Currants should be planted in masses. *Kölreuteria paniculata* is very attractive towards the close of September, when the deep green foliage assumes brownish-orange and crimson tints. *Oxydendron arboreum* (Sorrel-tree) has lovely crimson leaves in autumn.

Enkianthus campanulatus is very showy in October, as its reddish-orange leaves are quite distinct; while if grown in a clear atmosphere its winter effect is very fine, as its bark is highly coloured. Some of the Spindle-trees (Euonymuses) stand out in bold relief in autumn time. The beauty of *E. europæus* as a berry-bearing shrub is known far and wide, as its orange-coloured berries and bright crimson capsules are very pleasing; but no less so are the orange and brown tints of its autumn foliage. The variety *atropurpureus* is deep purple in spring and summer, and heavily shaded with orange in autumn. *E. obovatus*, allied to *E. americanus*, is also noteworthy; the leaves die off shades of reddish-purple and yellow. The square-stemmed *E. alatus* is rich in its autumnal colouring. In autumn the Amelanchiers are aglow with rich and subtle shades of yellow, chocolate, and crimson. Perhaps the most useful and ornamental is *A. canadensis*. The variety *oblongifolia*, however, is conspicuous for its claret-coloured leaves, and forms a striking contrast to the type.

Pyrus arbutifolia is not only desirable for its gorgeous Autumnal Tints, but also for its red fruits. All the forms of *Pyrus Aria* (Beam-tree) are more or less beautiful, and worth planting in the park alike for their charming foliage and attractive berries. Either for growing in the open shrubbery, or for training against a wall 6ft. or so high, *Spiræa prunifolia fl. pl.* should be remembered. In autumn its small Plum-like leaves are deeply stained with purplish-crimson. The yellow-barked Ash (*Fraxinus excelsior aurea*) is not only conspicuous by reason of the golden-yellow shades of the decaying leafage, but in mid-winter its brightly-coloured bark lights up the landscape. The White Ash (*F. americana*) is lovely when its large leaves are shaded with brown and orange. *Cladrastis tinctoria* in summer has the leaves a pretty shade of pale green, which in autumn gives place to rich yellow.

Those who have seen *Parrotia persica* in the weak sunshine of an October day cannot readily forget the effect produced by its Hazel-like leaves, which assume the most brilliant shades of crimson and yellow. *Betula populifolia* makes a pretty picture, especially on a moonlight night, with its brownish-yellow leaves mingling with the green ones; while the white-barked

Autumn Tints—*continued.*

stem gives pleasing variety. The purple-leaved form of the European species also deserves mention, as its autumnal colouring is quite as distinct and pleasing as its spring tints. Although introduced nearly a century ago, *Clerodendron trichotomum* is by no means well-known, notwithstanding its acknowledged beauty and hardiness. When its blossoms have faded, the reddish-purple calyces stand out prominently, affording a pleasing contrast to the beautiful shades of chocolate-brown and orange assumed by the decaying foliage. *Nyssa sylvatica* has smooth green leaves, which turn to brilliant shades of crimson and claret in autumn. *Liquidambar styraciflua* (Sweet Gum-tree) has deeply-lobed leaves, which in a young state are glossy green, and in October purplish-crimson.

Æsculus Hippocastanum (Horse Chestnut) in autumn assumes pleasing shades of orange and brown, while the leaves of *Æ. flava* turn bright yellow. The Maples (*Acer*) are grand trees for the park and garden, and the following are particularly showy in autumn: *Acer rubrum* holds a high place amongst Autumn-Tinted trees, for in October its leaves and petioles turn to shades of crimson, orange, and yellow. *A. circinatum* is very attractive when its leaves are stained with crimson and scarlet in autumn. *A. tataricum* has small serrated leaves which die off a lemon shade. Then there are *A. t. Ginnala* (sometimes given specific rank), whose soft green leaves change to various shades of bronze, red, and crimson before they fall, the bright red petioles affording additional colour; *A. macrophyllum*, with its large divided yellow and gold leaves set on red petioles; and *A. pictum*, whose leaves change from green to different shades of orange, yellow, and brown.

Of the Norway Maple (*A. platanoides*) two varieties stand out prominently above all others—*Reitenbachii* and *Schwedleri*. The first-named differs from the type principally on account of its metallic-green leaves, which intensify in colour before they fall; while *Schwedleri* has bronze-green leaves, changing to gold and deep crimson as autumn approaches. The under-sides of the leaves are nearly old-gold colour. Another sort, *A. insigne*, is worthy of mention, as in autumn its leaves change to yellow. *A. Heldreichi*, a native of Eastern Europe, is also conspicuous in autumn, its yellow leaves contrasting strongly with its crimson foot-stalks. *A. japonicum aureum* is a grand tree, whose beauty is shown from the time its clear yellow leaves are unfolded in spring until they die off in October, when they are heavily tinted and margined with crimson. The variety *microphyllum*, with its deeply-cut leaves, assume delicate shades of crimson and orange. *A. j. vitifolium* stands out conspicuously on a sunny autumn day, when the deeply-cut leaves (not unlike some of the Vines) are a mass of crimson and gold. *A. laciniata* enriches the landscape with glowing shades of orange, scarlet, and crimson. *A. macrantha* is showy, with its small blood-red leaves and petioles and red stem.

The Cotoneasters are prized for their lovely berries, but *C. horizontalis* deserves special mention, as it is the most conspicuous member of the genus when its decaying leaves present such vivid shades of scarlet and crimson. *Carya tomentosa* (White Heart Hickory) arrests attention principally on account of its lovely golden-yellow leaves, composed of from seven to nine leaflets; it is, when properly placed, one of the most gorgeous of Autumn-Tinted trees. *C. porcina microcarpa* is equally beautiful, the decaying foliage being particularly bright. *Vaccinium corymbosum*, in October, is rendered attractive by reason of its brightly-coloured foliage, which is a lovely shade of red, not infrequently intermingled with various shades of green and brown. *V. padifolium* and *V. pennsylvanicum* are likewise showy in their Autumn Tints.

Dogwoods (*Cornus*) are represented in nearly all public parks and gardens by one or two sorts only. *C. alba*, with its red stems and variously-coloured Autumn Tints, is a well-known decorative shrub, especially for winter effect, and the variety, *Späthi*, one of the best of the variegated Dogwoods, is becoming fairly well-known, too. The leaves are a beautiful yellow, marked with pale green, which, in autumn, is shaded with lemon-yellow and splashed with red. *C. florida* has leaves heavily shaded and suffused with chocolate-brown and golden-yellow. *C. brachypoda variegata* (a silver variegated form) assumes a bronzy-yellow shade. *C. macrophylla* is variable as regards its tints, and sometimes its leaves are not so highly coloured as at others. The small yellowish-green leaves of *C. mas elegantissima* are very attractive in October, when irregularly margined with red. *Lonicera Maximowiczii* is about the only Honeysuckle conspicuous for its autumnal colouring—rich shades of yellow and lemon.

The Sumachs (*Rhus*) are handsome tropical-looking plants, which "take on" pretty Autumn Tints. *R. Cotinus* (Venetian Sumach) is very noticeable; its leaves, which are retained longer than those of most of its congeners, are very showy. *R. cotinoides* deserves special mention on account of the dazzling colours of the decaying foliage, which are unequalled by any hardy tree. The normal colour is soft green, which, in early autumn, changes first to bronze-green, and later on to the brightest and most striking shades of orange-scarlet. Glorious shrubs for effect are *R. glabra*, and its variety *laciniata*. The latter is superior to the type; it is a valuable addition to the sub-tropical garden, the leaf-colour in autumn being a mixture of orange, yellow, and red.

Viburnum Opulus (Guelder Rose) bears leaves which are heavily stained with crimson and brown. *V. plicatum*, *V. Lantana*, *V. nudum*, and *V. cassinoides* are also worthy of mention, too.

The Oak is more often associated with the park than with the garden. *Quercus coccinea* (Scarlet Oak) gives colour to the landscape in autumn and early winter which is equalled by few trees. The colour varies from bronze-green to deep crimson. *Q. heterophylla* is dull crimson; *Q. palustris* (Marsh Oak) changes to yellow and red; *Q. marilandica nana*, a small tree, colours finely in an open situation, the leathery leaves being bright green in summer and rich purple-brown in autumn; the large foliage of *Q. velutina* dies off rich crimson; and *Q. conferta* (Hungarian Oak), with its deeply-cut leaves, is gay in October when shaded with cinnamon, brown, and yellow.

Of Azaleas or, more correctly, Rhododendrons, the *mollis*, or *sinensis*, and *pontica* sections are particularly noteworthy in autumn. Barberries are principally planted for their flowers in spring and fruit in autumn; some of them are brilliant towards the close of the summer months, when the leaves are changing colour. *B. Thunbergi* is effective when its small leaves assume shades of orange, yellow, chocolate, and brown. Sprays are admirably adapted for mixing with cut-flowers. Another species—*B. concinna*—has tiny green leaves, glaucous on the under-sides, which turn to bright red. *B. virescens* should be planted freely; its leaves die off a reddish colour, and the red stems are effective in the shrubbery during winter. The decaying leaves of *B. angulosa*, a loose-habited bush, are conspicuous in October. *B. vulgaris* and the purple-leaved *foliis-purpureis* has foliage which is delightful from early spring to autumn. In a young state the leaves are deep purple, and ere they fall the colour changes to bronzy-purple. *B. Aquifolium* (Holly-leaved Barberry), an evergreen member of the genus, is a pleasing shrub at all seasons of the year, but particularly so in autumn and winter, when its summer greenery has given place to shades of bronze and brown, and in not a few cases to crimson and maroon. *Nandina domestica*, a delightful little shrub, has smooth compound leaves which are bright red in autumn, and not only are they amongst the first to change colour, but being persistent, remain attractive for a considerable time.

Autumn Tints—*continued.*

Sprays or leaves are effective when used in conjunction with flowers for table decorations.

Two Leucothoës are deserving of recognition—*L. Catesbæi* (*Andromeda Catesbæi*), bearing long, sharp-pointed, bronzy-purple leaves throughout the winter, and *L. recurva*, with purplish-scarlet leaves in autumn. *Gaultheria procumbens* (Partridge Berry) is a cheerful-looking evergreen, with leathery leaves heavily shaded with bronze and crimson in winter.

Now as to climbers. These should include *Actinidia Kolomikta*, an uncommon free-growing climber, which gives a good account of itself in autumn, as the decaying leaves are heavily shaded with yellow, thus forming a good contrast to the reddish-coloured footstalks. Although usually accommodated in unheated plant-houses, *Akebia quinata* is hardy—in the temperate parts of these isles, at all events. In a young state its leaves are glossy green, but with age become suffused with brownish-purple. There are perhaps no more popular climbers for draping ugly walls than the Virginian Creepers, which in October are the admiration of everybody by reason of the superbly varied leaf-colours. Certainly no climbers are grown so extensively in town gardens, notwithstanding that they are bereft of foliage for a considerable portion of the year. *Vitis quinquefolia* (*Ampelopsis hederacea*) and *Ampelopsis Veitchii*, now recognised as *Vitis inconstans*, are unquestionably the finest of self-clinging deciduous creepers. The leaves vary in both shape and size, but the autumn colouring is always brilliant—shades of crimson, chocolate, and orange. *V. Coignetiæ*, which has received a great deal of notice during the past few years, and *V. Thunbergi* are both glorious in their autumn dress. *V. Teinturier*, a purple-leaved form of *V. vinifera*, is very beautiful, and deserves special mention.

Ivies possess considerable autumn beauty when judiciously used. *Hedera Helix atropurpurea* (*H. nigra*) in the early stages has glossy green leaves, but as winter approaches the colour changes to a lovely shade of bronzy-purple, in which condition it remains until the following spring.

Conifers form an interesting group. The colour of some intensifies in autumn and winter, and *Cryptomeria japonica elegans* will at once occur as a typical example. Then there is *Retinospora ericoides*—now merged into the *Thuia* group—whose small sharply-pointed leaves are heavily shaded with violet from autumn to spring. The majority of the Biotas and Thuias also arrest attention in winter on account of the variously-coloured foliage.

Two deciduous sorts stand out prominently amongst autumn-coloured trees—the Golden Larch (*Pseudolarix Kæmpferi*), with clusters of soft green leaves which change to golden-yellow in the early part of October, and *Taxodium distichum* (deciduous Cypress) which, from a colour point of view, is most conspicuous in its autumn dress, although it is very elegant in spring, when its feathery foliage is being moved by a gentle breeze. Before the leaves fall the colour becomes dull red and yellow, and if near enough to be reflected in water on a sunny day the effect is superb.

AVENUES. In forming an Avenue among the chief mistakes made are planting the trees in unsuitable soil, and not giving sufficient space between each specimen to allow of its individual character being displayed to advantage. Every Avenue should, if possible, be terminated with some definite object—for instance, a pagoda, tower, open scenery, &c. Then, again, the width of the Avenue, as well as the amount of room between the trees, should be well considered beforehand. The kind of tree employed must of course decide this, as it would be absurd to allow such things as Robinias (Acacias) the same amount of space as Limes, Chestnuts, or Elms. On low-lying wet soils it would be an advantage to plant on slightly-raised mounds, providing for drainage by means of broken bricks, stones, and such-like material.

Avenues—*continued.*

The value and beauty of the Horse Chestnut as an Avenue tree have been exemplified on many estates in this country, and the noble examples in Bushey Park, near Teddington, are of world wide repute. Although hardy, it should always be planted in sheltered positions, as its branches, being very heavy, are apt to split and fall off in rough weather. *Fagus sylvatica*, although not largely employed as an Avenue tree, deserves mention. It stands boisterous weather well, succeeds best in moist soil, and an Avenue of shapely trees is effective. It is an advantage to transplant the Beech frequently in a young state, so as to encourage as many fibrous roots as possible. An Avenue of the purple-leaved variety would not be so attractive as one composed entirely of the type, as the colour seen in the mass would be too heavy. Used with discretion in the park, it is, however, capable of producing splendid effects.

The fragrant Lime is a cherished Avenue tree; and rightly so, for it is well adapted to such a form of culture. A moist, well-drained soil answers admirably, as when planted in very dry land it loses a large number of leaves prematurely, especially in hot, dry seasons. The autumn-tinted foliage is very attractive. The Plane-tree (*Platanus acerifolia*) is familiar to everybody as the best of all trees for town planting. Vigorous, free in growth, and thoroughly hardy, it succeeds in all soils and positions. The Acacia is also a grand tree for towns, but unfortunately not used so much as it might be. In some respects it is superior to the last-named, as it is not so vigorous, stands hard pruning better, and may be employed with better effects in restricted areas. The foliage is a rich and pleasing shade of green. For small Avenues, *Acer Negundo* is well adapted, and *Liquidambar styraciflua* also merits attention for Avenues where the larger-growing sorts would be out of place. *Liriodendron tulipifera* grows freely, and forms a noble tree with a tall erect stem, and spreading branches supplied with deep green four-lobed leaves.

Several Elms (*Ulmus*) are serviceable Avenue trees, and the large-leaved English is one of the best. The upright-habited variety is worthy of extended culture. For general purposes the Atlas Cedar (*Cedrus atlantica*) is much better and hardier than *C. Deodora*, which is often employed as an Avenue tree.

For long and very broad Avenues *Quercus Ilex* answers well. The best specimens are produced in moist, deep soils, and when thoroughly established they grow freely. *Q. Turneri* is another ornamental Oak of free growth. *Abies brachyphylla*, a somewhat rare Japanese species, makes a handsome Avenue tree, but it requires good soil and shelter from north and east winds. *A. Nordmanniana* is perhaps the best of all the Silver Firs for decorative purposes; it succeeds in all soils and exposed situations. *A. Douglasii*, now botanically recognised as *Pseudotsuga Douglasii*, is a grand tree, with its tall stem, horizontal branches, and lovely foliage. *Picea pungens glauca* is a particularly showy and thoroughly hardy Conifer. It is of excellent growth in good soil, with an erect stem and stout branches.

Cryptomeria japonica is an upright-growing tree, whose stem is covered with rough brown bark. Protection from biting winds and an open soil should be secured for it. *Thuia gigantea*, a vigorous North American Conifer, also makes a suitable Avenue tree. It has an erect trunk, short branches, and deep green leaves. *Pinus excelsa*, *P. Strobus*, and *Wellingtonia gigantea* (under favourable conditions) are also serviceable Avenue trees. *Araucaria imbricata* has been planted extensively as an Avenue tree, as well as a lawn and park tree. It is sometimes made to cut ridiculous figures in the front gardens of many suburban villas. To see the true beauty of this peculiar tree, rich soil and a clear atmosphere are necessary. Its value as an Avenue tree has, however, been over-estimated.

AVERRHOA. Only the two species described are included in this genus. They are indigenous in tropical Asia. Flowers small, cymulose, regular; sepals five, imbricated; petals five, hypogynous, twisted; stamens ten; cymes in short panicles. Leaves alternate, imparipinnate, exstipulate. *A. Bilimbi* is known as the Cucumber-tree.

AVERRUNCATOR. This useful implement is better known as the Standard Tree Pruner, and is in use in most gardens where tall trees have to be pruned. Probably the best is that made by the Standard Tree Pruner Co., Derby, as it is easy to work and handle, making clean cuts. It is made in various sizes, and considerably economises labour.

AVICENNIA (named in honour of Avicenne, a celebrated Arabian philosopher and physician, 980-1037). SYNS. *Bontia* (of Linnæus), *Donatia*, *Halodendron* (of Thouars), *Sceura*, *Upata*. ORD. *Verbenaceæ*. A small genus (three or four species) of glabrous or canescent, stove shrubs, broadly dispersed over the sea-shores of the warmer parts of the globe. Flowers small, sessile, in contracted, head-like, pedunculate cymes; calyx five-parted; corolla limb five-cleft; stamens four; bracts shorter than the calyx. Leaves opposite, entire, coriaceous. *A. nitida* and *A. officinalis* are occasionally grown in Continental gardens, but they have little decorative value.

AWN. A bristle-like appendage; *e.g.*, those on the glumes of many of the Grasses.

AXE-WEED. *See* **Securigera Coronilla.**

AYENIA (named in honour of the Duke d'Ayen). SYN. *Cybiostigma*. ORD. *Sterculiaceæ*. A genus comprising eight species of stove herbs or sub-shrubs, natives of the warmer parts of America. Flowers small, pedicellate, fascicled or cymose; calyx five-parted; petals five. Leaves serrated. *A. lævigata* and *A. pusilla* have been introduced, but are probably no longer in cultivation.

AYRSHIRE ROSE. *See* **Rosa repens hybrida.**

AZALEA. This genus is now included by the best authorities under **Rhododendron.**

Thrips, Red Spider, and most of the other animal pests to which Azaleas are liable are now best got rid of by means of the XL All Vaporiser. This may be used without the least injury to the tender foliage. More troublesome to the cultivation of Azaleas indoors is, however, bud-dropping, which usually follows if the plants do not receive a sufficiency of moisture at the roots.

To the species, varieties, and hybrids described on pp. 149-50, Vol. I., the following should be added:

A. balsaminæflora alba (white). *fl.* white, produced in large, compact trusses, and lasting a long time in perfection.

A. b. aurea (golden). A form differing from *alba* in its bright yellow flowers.

A. b. carnea (flesh-coloured). *fl.* flesh-coloured, tinted with rose, and also with pale yellow when first expanded. 1887.

The preceding are garden hybrids raised from a Javanese species.

A. dianthiflora (Dianthus-flowered). *fl.* of a rose or violet colour, dotted with brown, sweet-scented; calyx lobes long, pubescent; corolla 3in. in diameter; pedicels tomentose. May and June. *l.* rather large, elliptic-oblong, softly hairy. Japan, 1889. A vigorous, free-flowering, hardy shrub.

A. hybrida Daviesii (Davies' hybrid). *fl.* white. 1893. A garden hybrid, supposed to have originated by crossing *A. sinensis* with *A. viscosa*. (R. G. 1387.)

A. nitida (shining). A form of *A. viscosa*.

A. obtusa (blunt). *fl.* deep red, solitary; segments of the corolla nearly oval and sharp-pointed, the upper one not much smaller than the others, and faintly blotched purple. March. *l.* pilose, oblong, obtuse, narrowed at base. *h.* 2ft. China, 1844. Greenhouse evergreen. (B. R. xxxii. 37; G. C. n. s., xxv., p. 585.)

A. o. alba (white). A variety differing from the type only in the colour of its flowers, which are white, occasionally striped red. 1887.

A. occidentalis (Western). *fl.* rather unpleasantly scented, produced when the leaves are almost fully developed; corolla white or rarely having a slight rosy tinge and a pale yellow band on the upper lobe, often 2½in. long. *l.* obovate-oblong, 1in. to 3in. long, nearly glabrous at maturity, but ciliated, thickish. *h.* 2ft. to 6ft. California.

A. rhombica (rhomboid-leaved). *fl.* usually in pairs; calyx minute; corolla bright rose, 1½in. to 2in. across, sub-bilabiate. May. *l.* sub-conical, 1½in. to 2in. long, assuming a bronzy hue in autumn, the young ones silky, rhombic-elliptic, acute at both ends, hairy above, finely reticulated beneath. Branches slender, stiff, glabrous, the young ones strigose-tomentose. Japan. A much-branched, hardy shrub. SYN. *Rhododendron rhombicum* (B. M. 6972).

A. rustica (rustic). This name has been applied to a garden race, said to be derived from *A. sinensis* (*mollis*) and *A. occidentalis*. 1893.

Indian Azaleas. The following new varieties in the various sections may be recommended:

Azalea indica.—*Double-flowered*: BARONNE ROTHSCHILD, rich purple; very fine. BERNARD ANDRE ALBA, pure white, large; semi-double. BIGNONCE FLORE PLENO, lovely rose, imbricated, large flower; very handsome. COMTE D'HAINAULT, rich salmon-pink, upper petals spotted with dark maroon; very large. DEUTSCHE PERLE, pure white; one of the finest of all varieties, very early, and forces well. EMPRESS OF INDIA, rosy-salmon; pretty and free. NARCISSIFLORA, pure white; a useful winter-flowering variety. QUEEN OF DOUBLE WHITES, pure white; fine. VERVAENEANA, salmon, margined with white; large and handsome.

FIG. 138. AZALEA INDICA.

Single-flowered (See Fig. 138): ALBA DELICATISSIMA, white; the foliage of this variety is richly variegated. AMI CHARLES VERMEIRE, crimson, with spots of a deeper shade on the upper petals; of excellent form and substance. APOLLO, white, striped with carmine; a large and splendid variety. BEAUTY OF SURREY, pure white; a fine variety of good form. GRANDIFLORA ALBA, pure white; one of the largest and best of the new varieties; GRANDIS, brick-red; an excellent variety. HERCULES, rosy-crimson, with dark blotches on upper petals; very large. MADAME JEAN NUYTENS VERSCHAFFELT, soft satiny white, slightly tinged with yellow at the margins; a large and lovely variety. STELLA, rich orange-scarlet, tinged with violet on the upper petals; a splendid large flower.

Azalea pontica.—ADMIRAL DE RUYTER, reddish-scarlet; AUGUSTE MECHELYNCK, white; BEAUTE CELESTE, bright rose; BIJOU DES AMATEURS, rose; BOUQUET DE FLORE, salmon; CARDINAL, flesh colour; COCCINEA SPECIOSA, deep orange; DAVIESII, white; FAMA, rose, shaded with yellow; GLORIA MUNDI, vermilion; HEUREUSE SURPRISE, pure white; IGNEA NOVA, carmine; MINERVA, rosy-salmon; NANCY WATERER, a lovely yellow; PALLAS, rose-magenta; PUCELLE, light violet; PRINCESS ADRIENNE, deep red; QUEEN VICTORIA, deep rose; UNIQUE JAUNE, deep yellow; and WILLIAM III., orange.

Azalea rustica flore pleno.—AIDA, rose, spotted with yellow; ARIADNE, white, shaded with rose; FREYA, whitish mauve, shaded with yellow; HORA, nankin yellow; IL TASSO, light red; MÉCÈNE, white, marked with rose; PHIDIAS, light rose,

Azalea—*continued.*

shading to deep yellow; VELASQUEZ, creamy-white, shaded with rose; VIRGILE, pale yellow.

Azalea sinensis (SYN. *A. mollis*).—ALBICANS, pure white; ALPHONSE LAVALLEE, reddish-orange; BARON EDMOND DE ROTHSCHILD, red; BARON PIGCKE, deep red; CHEVALIER DE REALI, bright light yellow; COMTE DE GOMER, rosy-orange; COMTE DE QUINCEY, golden-yellow; ERNEST BACH, red; ISABELLA VAN HOUTTE, clear nankin; KÖNIGEN SOPHIA, orange suffused with rose; PROFESSOR W. KOSTER, red; and W. E. GUMBLETON, nankin.

Azalea sinensis Hybrids.—CHARLES ROGIER, bright rose; DULCINÉE, reddish-orange; EDISON, rose; FRERE ORBAN, creamy-yellow; GENERAL BRAILMONT, rosy-lilac; GLOIRE DE BELGIQUE, lovely red; J. J. DE VINT, pale orange, immense truss; M. DESBOIS, salmon; SOUVENIR DE LOUIS VAN HOUTTE, white, tinged with rose.

AZALEASTRUM ALBIFLORUM. A garden synonym of **Rhododendron albiflorum** (which *see*).

AZALEODENDRON (a compound of the names *Azalea* and *Rhododendron*). ORD. *Ericaceæ*. This name has been applied to so-called bigeneric hybrids between *Azalea sinensis* (*mollis*) and some varieties of *Rhododendron*. They should properly be classed under *Rhododendron*, in which genus Bentham and Hooker include *Azalea*.

AZARA. About a dozen species, all natives of Chili, are included in this genus. Flowers hermaphrodite, fascicled, shortly corymbose, or somewhat spicate; sepals four or five and somewhat valvate, or five or six and imbricated; petals wanting; stamens indefinite.

AZEREDIA. A synonym of **Cochlospermum** (which *see*).

AZIMA (from *Azimena*, the Malagasy name of an allied shrub). SYN. *Monetia*. ORD. *Salvadoraceæ*. A small genus (three or four species) of stove or greenhouse, much-branched or sarmentose shrubs, natives of tropical Asia, tropical and South Africa, and Madagascar. Flowers small, dicœcious, crowded in the axils or in panicles at the sides of the branches. Leaves opposite, entire. *A. tetracantha* (SYN. *Monetia barlerioides*) has been introduced, but is probably lost to cultivation.

AZOLLA (from *azo*, to dry, and *ollo*, to kill; a dry condition causes the plants to perish). ORD. *Rhizocarpeæ*. A genus embracing five species of stove or greenhouse, fugacious, floating aquatics, with copiously-branched stems, natives of North and South America, Australia, and New Zealand. Leaves sessile, minute, densely imbricated, deeply lobed, each lobe furnished with a midrib only. Stems sending out from the under-side into the water copious simple or feathery, solitary or fascicled root-fibres; branches bearing two kinds of fruit on the under-side (which, however, is not usually seen in this country). The only species in cultivation is best accommodated during the winter in shallow vessels in a pit or warm house, or frame; but in the summer it will thrive in a small indoor aquarium, or the vessel in which it grows may be placed outside, and at this season acquires a rich reddish-purple tint.

A. caroliniana (Carolina). *fronds* ¼in. to 1in. long. *l.* generally pale green, the larger lobes rhomboid-oblong, obtuse. Root-fibres solitary. Southern United States to Buenos Ayres.

BABIANA. The species number nearly thirty. To the information given on p. 152, Vol. I., the following should be added:

B. disticha is scarcely more than a variety of *B. plicata*, from which it differs by its perianth-tube being distinctly exserted from the spathe (J. G. Baker).

B. reflexa is a form of *B. stricta* with flowers smaller than in the type, the lower ones deflexed.

B. socotrana (Socotran). *fl.* solitary, almost sessile; perianth tube 1¼in. long, very slender, the limb pale violet-blue, 1in. broad, two-lipped, the segments elliptic, acute. September

Babiana—*continued.*

l. bifarious, 3in. to 4in. long, ¾in. broad, narrow-lanceolate; petioles broad, compressed. *h.* 3in. to 4in. Socotra, 1880. (B. M. 6585.)

B. stricta. *B. villosa* (B. M. 583) is synonymous with this species.

BABINGTONIA. Bentham and Hooker include this under **Bæckea** (which *see*).

BACAZIA. Included under **Barnadesia** (which *see*).

BACCAUREA (from *bacca*, a berry, and *aurea*, golden; in allusion to the golden berries of some of the species). SYNS. *Adenocrepis*, *Calyptroon*, *Microsepala*, *Pierardia*. ORD. *Euphorbiaceæ*. A genus embracing upwards of thirty species of stove trees, natives of India, the Malayan Archipelago, and the Pacific Islands. Flowers racemose, on short pedicels. Fruit ovoid, obovoid, or sub-globose. Leaves alternate, entire or lightly undulate-crenate. *B. bracteata* (SYN. *Pierardia dulcis*) has been introduced, but is probably no longer grown in this country.

BACCHARIS. SYN. *Molina*. Upwards of 275 species, all American, have been referred to this genus. To that described on p. 152, Vol. I., the following should be added:

B. salicina (Willow-like). *fl.-heads* pedunculate. *l.* like those of a Willow, sub-sessile, varying from oblong to linear-lanceolate, sparingly toothed, rarely entire. *h.* 6ft. Western North America, 1894.

B. trimera (three-parted). *fl.-heads* inconspicuous. *h.* 6ft. Argentina, 1896. A leafless, greenhouse shrub, with winged expansions along the stems. It is more curious than ornamental. (R. H. 1896, p. 152, f. 50-52.)

BACTERIA. These microscopic vegetable organisms, though popularly associated with certain diseases peculiar to man and other animals, are also responsible for several very destructive plant diseases, which are grouped under the heading of "Bacteriosis." Hartig, in his "Diseases of Trees," says that such diseases are characterised by the succulent parts of the infested plant being converted "into a slimy, glutinous pulp, which emits a most repulsive stench." Bacteria increase very rapidly by either fission or by spores. The first is really a process of self-division. It consists of a gradual division of the body into two parts, each of which then becomes a separate and independent organism. Dutch bulb growers are only too well aware of the appearance of Hyacinths so attacked by the yellow, slimy disease, found alike in the resting and active stage, and known as *Bacterium* (*Bacillus*) *hyacinthi*. Tomatoes are subject to a virulent form of Bacteriosis, in which the fruits are blackened. So also are Cabbages. In the latter case, Dr. Erwin Smith (of the United States Department of Agriculture) says the symptoms usually begin at the margins, and consist in the yellowing of all affected parts except the veins, which become decidedly brown or black. Carnations, again, are affected. A number of other plants not grown in this country are thought to be affected by these low organisms, but the whole question of Bacteria in their relation to plants requires further investigation before anything can with certainty be said.

BACTERIOSIS. *See* **Bacteria.**

BACTRIS. About a hundred species of this genus, all natives of tropical America, have been enumerated. To those described on p. 153, Vol. I., the following should be added:

B. acanthocarpa (spiny-fruited). *fl.*, spadix about 1½ft. long. *fr.* scarlet, globose or depressed-globose, armed with long, black, shining prickles. *l.* 6ft. to 8ft. long, scattered on the upper part of the stems, spreading; pinnæ rather loosely disposed, linear, long-acuminate, 1½ft. long. Stems often densely tufted, erect, 12ft. to 15ft. high, very prickly. Brazil. There is a variety *crispata*.

B. elatior (taller). This "may belong to *B. trichospatha*, with which it agrees in habit, but from which it differs in the regular arrangement and smaller number of the pinnæ, in the arrangement of the branches of the spadix, the rachis being represented

Bactris—*continued.*

long, while in *trichospatha* it is short or nearly wanting" ("Journal of Botany," xv., p. 42). Brazil.

B. Gasipaés (native name). A synonym of *Gulielma speciosa.*

B. simplicifrons (entire-leaved). *fl.*, spadix simple, 1in. to 2in. long, nodding; inner spathe as long as the spadix, glabrescent. *l.* bifid, the two divisions oblong, entire, curved, acute, 10in. to 12in. long, 2½in. to 3in. broad, broadly adnate at the flat base, diverging in an acute angle. Trunk 3ft. to 6ft. high. West Indies, &c. Plant devoid of prickles except at the tips of the leaves.

B. trichospatha (hairy-spathed). *fl.*, outer spathe pubescent, inner one almost woody; spadix 8in. to 14in. long. *fr.* blackish-violet, globose, ½in. in diameter. *l.* 4ft. to 7ft. long, interruptedly pinnate; leaflets all on the same plane, lanceolate, slightly falcate, long-acuminate, pale beneath. Caudex dwarf, unarmed or prickly. Brazil.

BACULARIA. SYN. *Linospadix.* Flowers green, monœcious on the same spadix; spadices numerous, very slender, simple, longer than the leaves; spathes two, remote. Fruit green, ¼in. to ½in. long. Leaves terminal, unequally pinnatisect; segments cut or toothed at apex. To the species described on p. 153, Vol. I., the following should be added:

B. Micholitziana (Micholitz'). *l.* oblong; leaflets remote, linear-oblong, acute, paler on the under-surface. Caudex and rachis furnished with scattered spines, which are thickened at the base. New Guinea, 1898. A very elegant Palm in a young state. SYN. *Ceratolobus Micholitziana* (G. C. 1893, xxiii., p. 251; R. H. 1898, p. 263).

B. Petrickiana (Petrick's). A very elegant, pinnate-leaved species, as yet very rare in cultivation. New Guinea, 1898. SYN. *Linospadix Petrickiana* (G. C. 1898, xxiv., p. 299, f. 87).

BADAMIA. Included under **Terminalia** (which *see*).

BÆA. About seven species are included in this genus; they are found in Eastern Asia, the Malayan Archipelago, Australia, and the Seychelles. Flowers blue, on axillary peduncles or elongated, leafless scapes; calyx five-parted or deeply five-cleft; corolla tube short, the limb somewhat bilabiate; perfect stamens two. Leaves radical, or those on the stems short and opposite, ovate or oblique.

BÆCKEA. Bentham and Hooker include **Babingtonia** (which *see*) under this genus; it embraces nearly fifty species, mostly Australian, a few being found in the Indian Archipelago and in New Caledonia.

BAEL-TREE. *See* **Ægle Marmelos.**

BÆOBOTRYS. A synonym of **Mæsa** (which *see*).

BÆOMETRA (from *baios*, small, and *metron*, size, in allusion to the size of the plant). SYNS. *Jania*, *Kolbea.* ORD. *Liliaceæ.* A monotypic genus. The species is a greenhouse, bulbous plant, thriving in a compost of sandy loam and peat, and increased by seeds or by division.

B. columellaris (Columella-like). *fl.* one or few in a simple raceme, shortly pedicellate; perianth red outside, yellow within, with a black spot at the base of the blade. June. *l.* several, dry, persistent, firm, the lower ones 6in. to 9in. long, stem-clasping, the upper ones gradually smaller. Stems simple, 6in. to 12in. high. South Africa, 1787. SYN. *Melanthium uniflorum* (B. M. 767).

BÆRIA. SYN. *Burrielia* (in part). The species are all Californian. Flower-heads yellow, heterogamous, radiate, at the tips of the branches or long-pedunculate or axillary; involucral bracts in one or two series; receptacle conical. Leaves opposite, linear, entire, pinnatifid or pinnately cut. To the species described on p. 153, Vol. I., the following should be added:

B. gracilis (slender). *fl.-heads* solitary, having ten to twelve rays and involucral bracts, or when depauperated five or six, the former nearly ½in. long. Summer. *l.* linear, entire. *h.* 6ft. to 10ft. 1887. A hardy annual, branching from the base. (R. G. 1887, p. 392.) SYN. *Burrielia gracilis* (B. M. 3758).

BAHIA. SYN. *Trichophyllum.* Including *Eriophyllum.* There are about a score species of greenhouse or hardy under-shrubs in this genus, all American. Flower-heads yellow, heterogamous, radiate; involucre flat, naked or foveolate. Leaves opposite or alternate, dissected or lobed,

Bahia—*continued.*

or the upper ones entire. To the species described on p. 154, Vol. I., the following should be added:

B. confertiflora (cluster-flowered). *fl.-heads* disposed in small, dense, corymbose cymes; ray florets four or five. *l.* small, mostly of cuneate outline, pinnately or somewhat ternately once or twice three- to seven-parted into narrow-linear divisions. Stems naked at summit. *h.* 1ft. to 2ft. North America, 1888. An ornamental, white-woolly, hardy under-shrub. (R. G. 1888, p. 329, t. 1275, f. i.) SYN. *Eriophyllum confertiflorum.*

BAKED. This term is applied to soil which has become set or hardened on the surface by the action of sun and wet. The condition is very noticeable where the soil is clayey or a mixture of clay and sand. Soil should be prevented from baking in a garden by the frequent use of the Dutch hoe in dry weather. Farmyard manure will also act mechanically on the soil; while road-scrapings, ashes, or any other material that will lighten the soil and render it more friable, are beneficial.

BAKERIA (named in honour of John Gilbert Baker, F.R.S., F.L.S., an eminent botanist, author of the "Handbook of the *Bromeliaceæ*," and numerous other works). ORD. *Bromeliaceæ.* A monotypic genus. The species is a stove or warm greenhouse, stemless plant, requiring similar culture to **Tillandsia** (which *see*).

B. tillandsioides (Tillandsia-like). *fl.* rosy-purple, about ½in. in diameter, rather pretty; petals much longer than the sepals; inflorescence a loose panicle, 1ft. long, with ascending or spreading, racemose branches; peduncle slender, about as long as the leaves. September. *l.* densely rosulate, spreading, ensiform, acuminate, 6in. to 8in. long, ½in. broad. Probably Brazil. (R. H. 1889, p. 84.)

BAKERIA (of Seemann). Included under **Pleurandra** (which *see*).

BALAKA (probably a native name). ORD. *Palmæ.* A small genus of stove Palms. *B. perbrevis* and *B. Seemanni*, both natives of Fiji, are included in the Kew Collection, but they are not in general cultivation.

BALANOPHOREÆ. A natural order embracing about thirty-five species (in fourteen genera) of fleshy, parasitic herbs, of botanical interest, allied to the *Euphorbiaceæ.*

BALANOPSEÆ. A small natural order (six or seven species, in one genus) of New Caledonian trees or shrubs, of botanical interest, allied to the *Urticaceæ.*

BALANOPTERIS. A synonym of **Heritieria** (which *see*).

BALANTIUM (of Kaulfuss). Included under **Dicksonia** (which *see*).

BALBISIA. SYN. *Cruikshanksia* (of Hooker). According to the "Index Kewensis," this genus includes three species; they are of stove under-shrubs, natives of Chili and Peru. Flowers yellow, showy, terminal, solitary, regular; sepals five, imbricated; petals five, hypogynous, twisted; stamens ten, free. Leaves opposite or alternate, often three-parted, without stipules.

BALBISIA (of Willdenow). A synonym of **Tridax** (which *see*).

BALFOURIA. A synonym of **Wrightia** (which *see*).

BALLOTA (*Ballote* is the Greek name of our native *B. nigra* [Black Horehound], and is said to be derived from *ballo*, to emit; in allusion to its rejection by cattle on account of its disagreeable smell). ORD. *Labiatæ.* A genus embracing about twenty-five species of greenhouse or hardy, perennial herbs, or under-shrubs, mostly found in the Mediterranean region; one is broadly dispersed over Europe and Western Asia, and one is South African. The species are of no horticultural value. *B. suaveolens* is now classed under **Hyptis** (which *see*).

BALSAM, GARDEN. *See* **Dianthera pectoralis.**

BALSAM, POPLAR. *See* **Populus balsamifera.**

BALSAM, SEASIDE. *See* **Croton Eluteria.**

BALSAM, WATER. *See* **Tytonia natans.**

BALSAMIFLUÆ. Included under **Hamamelideæ** (which *see*).

BALSAMINA. A synonym of **Impatiens** (which *see*).

BALSAMITA. This genus is included by Bentham and Hooker under **Chrysanthemum** (which *see*).

B. vulgaris (common). A synonym of *Tanacetum Balsamita.*

Bambusa—*continued.*

the dead leaves that have settled in the centre cleared away so as to allow a free circulation of air. An annual mulching of well-rotted manure or good leaf-mould will be of great benefit in adding vigour to the plants. Bamboos are the most charming of all plants for sub-tropical bedding, and for planting as isolated specimens on the lawn they have few equals. To those described on pp. 155-6, Vol. I., the following should now be added. For a full account of this and allied genera the reader is referred to A. B. Freeman-Mitford's monograph, entitled "The Bamboo Garden" (London, 1896). *See also* **Arundinaria** and **Phyllostachys.**

FIG. 139. BAMBUSA PALMATA.

BALSAMODENDRON. SYNS. *Commiphora, Heudelotia.* About half-a-dozen species, natives of Arabia, tropical and South Africa, and the East Indies, are referred to this genus.

B. zeylanicum is now classed under **Canarium.**

BAMBOO PALM. *See* **Rhaphia tædigera.**

BAMBOS. A synonym of **Bambusa** (which *see*).

BAMBUSA. SYNS. *Bambos, Ischurochloa.* About two dozen species have been referred to this genus, natives of tropical or sub-tropical Asia, one being broadly dispersed through tropical America. Bamboos should never be exposed to cold east winds, as these are far more injurious, especially when growth is tender, than severe frosts. The soil best suited to their development is a sandy loam, enriched with cow-manure and leaf-mould. In very dry soils Bamboos make but little growth, and in very hot and dry summers the foliage is apt to turn a rusty brown, and fall off prematurely. The plants should be examined in spring, and

B. angustifolia (narrow-leaved). *l.* 2in. to 4½in. long, ¼in. broad, tessellated, serrated on both edges, tapering to a fine point, pinched in about ¼in. from the end, sometimes striped with white. Stems 1ft. high, ¼in. thick, light green, shading to purple; branches solitary or in pairs, much longer than the internodes. China and Japan. A charming little species. SYN. *B. Vilmorini.*

B. Castillonis (Castillon's). *l.* 7in. long, 1½in. broad, serrated, variegated. Stems square, curiously variegated; one side of each internode is dark green, and the other side yellow, these colours alternating at the next internode. *h.* 6ft. Japan, 1886. Hardy. (R. H. 1886, p. 513.)

B. chrysantha (golden-flowered). *l.* 7in. long, 1½in. broad, striped with yellow, slightly glaucous beneath. Stems slender, 3ft. or more in height. Japan. This is probably a form of *Arundinaria Simoni.*

B. disticha (two-ranked). *l.* borne alternately in two vertical ranks all along the stems and branches, lanceolate, bright green, tessellated, serrated, 1⅜in. to 2¼in. long, ¼in. broad. Stems 2ft. high, zigzagged, rarely clouded with purple; sheaths downy at first; branches solitary. Japan (?). SYN. *B. nana* (of gardens).

B. erecta (erect). A synonym of *Arundinaria Hindsii.*

B. fastuosa (proud). *l.* 5in. to 7in. long, ¾in. to 1in. broad, sharp-pointed, constricted 1in. from the tongue-like end,

Bambusa *continued*

serrated, closely tessellated, brilliant green above, glaucous beneath; petioles long and well-defined. Stems 12ft. to 15ft. high, more than 3in. thick, very hollow, heavily blotched with purplish-brown; branches very numerous (sometimes eight to one node) and again ramified; sheaths of a beautiful purple outside, deep claret within. Japan, 1895.

B. gracilis (slender). A garden name for *Arundinaria falcata* and *A. Falconeri.*

B. graminea (Grass-like). A garden synonym of *Arundinaria Hindsii graminea.*

B. Henonis. *l.* narrow, 2in. to 3in. long. Stems 7ft. to 9ft. high. This is described "as one of the most beautiful of the genus, and one of the hardiest, bearing equally well the drought of summer and the ice of winter."

B. Hermanni (Hermann's). A garden synonym of *Arundinaria macrosperma.*

B. Kan-chiku (native name). A synonym of *B. marmorea.*

B. Laydekeri (Laydeker's). *l.*, largest ones about 6in. long and ⅝in. broad, tapering to a fine point, dark green, with a poor, paler variegation, tessellated, more serrated on one edge than on the other. Stems 3ft. or more in height, about ½in. thick, stained with purple; nodes prominent, 3in. to 4in. apart; branches almost whorled on the upper nodes. China and Japan. Not a handsome species; dies after flowering.

B. macroculmis (large-stemmed). A synonym of *B. arundinacea.*

B. marmorea (marbled). *l.* bright green, 4½in. long, ⅝in. to ¾in. broad, serrated, prettily tessellated, constricted about ½in. from the sharp point. Stems 3ft. or more in height, purple, solid throughout; internodes 1½in. to 2in. long; sheath purple, marbled with pinkish-grey; branches borne in threes. China and Japan. An ornamental species. SYN. *B. Kan-chiku.*

B. Maximowiczii (Maximowicz's). A garden synonym of *Arundinaria Simoni striata.*

B. Metake is a synonym of *Arundinaria japonica.*

B. Nagashima (native name). *l.* sometimes 5½in. long and ⅝in. broad, tessellated, serrated, bright green, finely pointed, pinched towards the top. Stems round, slender, purplish-green, 1ft. to 1½ft. high; main branches borne singly, but the branchlets in twos and threes. Japan.

B. nana (dwarf), of gardens. A synonym of *B. disticha.*

B. Narihira (native name). A synonym of *Arundinaria Simoni.*

B. Neumanni (Neumann's). A synonym of *Arundinaria macrosperma.*

B. palmata (palmate). *l.* 12in. to 13in. long, 3in. to 3½in. broad, tapering to a fine point, pinched in about 1in. from the end, very sharply serrated, conspicuously tessellated, brilliant green above, glaucous beneath; petioles stout. Stems about 5ft. high, 1in. thick, bright green with a waxy bloom. China and Japan. See Fig. 139.

B. palmata, of gardens. A synonym of *B. tessellata.*

B. plicata (folded). A synonym of *Arundinaria Simoni striata.*

B. pumila (dwarf). *l.* 4½in. long, ⅝in. broad, covered with short hairs. Stems less than 3ft. high, unbranched. Japan, 1894.

B. pygmæa (pigmy). *l.* 5in. long, ⅝in. broad, brilliant green, regularly tessellated, serrated, the upper surface bristling with little teeth, the lower downy; petioles well defined. Stems 6in. to 12in. high, with prominent nodes. Japan. A dwarf but very rampant species.

B. quadrangularis (four-angled). *l.* deep green, 8in. long, 1in. broad, serrated, minutely tessellated, lanceolate, pinched in about 1in. from the point, tapering to a short petiole. Stems 12ft. to 30ft. high, ¾in. thick, quadrangular, having a deep purple band on the lower side of each node; branches six or seven to a stem. China and Japan. Rare in cultivation.

B. Ragamowskii. The correct name is *B. tessellata.*

B. senanensis (a geographical name). *l.* ovate, 6in. long. Stems about 1ft. high, thin, erect. Japan, 1894. A hardy species, considered by Mr. Freeman-Mitford to be identical with *Arundinaria Veitchii.*

B. Simonii is synonymous with *Arundinaria Maximowiczii.*

B. sterilis (barren). A synonym of *Phyllostachys aurea.*

B. tessellata (tessellated). The correct name of *B. Ragamowski. fl.*, inflorescence a narrow panicle, on stems 1½ft. to 2ft. or more in length; spikes composed of five or six closely-set, one-flowered spikelets, on the moderately short branches (2in. to 2½in.) of the panicle. *l.* oblong, acuminate, 4in. to 8in. long, 1½in. to 2½in. broad, bright green above, bluish-green beneath, changing in autumn to yellow, or with a broad yellow border. Japan, 1888. A very ornamental, dwarf, hardy Bamboo, also known as *B. palmata, B. Ragamowskii* (see Vol. I.), and *B. Veitchii.*

B. Veitchii (Veitch's). A synonym of *Arundinaria Veitchii.*

B. Vilmorini (Vilmorin's). A synonym of *B. angustifolia.*

B. Wieseneri (Wiesener's). Stems brownish-black or dark olive-green. Japan, 1887. Garden variety. A fine, hardy Bamboo, resembling in habit and vigour *Arundinaria japonica* (this being the correct name of the plant described on p. 118, Vol. I., as *A. Metake*).

BAND-PLANT. *See* **Vinca major.**

BANISTERIA. No less than sixty species, natives of tropical America (especially Brazil), are comprised in this genus. Several plants formerly referred here are placed by modern botanists under **Heteropterys** and **Stigmaphyllon** (which *see*).

BANKSEA. A synonym of **Costus** (which *see*).

BANKSIA. About forty-six species of this genus have been described; all are Australian, and most of them extra-tropical. Flowers sessile, in pairs, disposed in dense spikes, terminal or axillary, crowded within the floral leaves; fruit-bearing spikes changing into thick, woody strobiles. To the species described on pp. 156-7, Vol. I., the following should be added:

B. ericifolia (Erica-leaved). *fl.* yellow; spikes cylindrical, 6in. to 10in. long. *l.* crowded, narrow-linear, truncate or notched at the end, otherwise entire, rarely exceeding ½in. in length, with closely revolute margins. *h.* 12ft. to 14ft. 1788. (A. B. R. 156; B. M. 738.)

B. grandis (large).* *fl.* yellow; spikes cylindrical, 8in. to 12in. long. *l.* often 1ft. or more in length, divided to the midrib into ovate-triangular, contiguous segments, the larger ones 1½in. to 2in. long, and 1in. broad at base, the lower ones gradually smaller, all flat, with several veins impressed above, prominent beneath, the under-surface pale. *h.* 40ft. 1794. One of the best of cultivated species.

B. integrifolia paludosa (marsh-loving). A variety having smaller flowers and shorter leaves than in the type. (B. R. 697, and L. B. C. 392, under name of *B. paludosa.*)

B. marcescens (weak). *fl.* purple; spikes dense, oblong or cylindrical, 3in. to 10in. long, like those of *B. media. l.* petiolate, oblong, truncate, serrated, almost obtuse at base, 1in. to 1½in. long, about ¼in. broad, flat, minutely tomentose beneath. Branches tomentose. *h.* 5ft. to 6ft. 1794. (B. M. 2803.) SYN. *B. præmorsa* (A. B. R. 258).

B. media (medium). *fl.* yellow; spikes oblong or cylindrical, 3in. to 6in. long. *l.* lanceolate-cuneate, truncate, serrated, 2in. to 3in. or more in length, ½in. to ¾in. broad, flat, tomentose beneath, tapering into short petioles. Branches hoary-tomentose. *h.* 6ft. 1824. (B. M. 3120.)

B. paludosa (marsh-loving). A form of *B. integrifolia.*

B. præmorsa (bitten). A synonym of *B. marcescens.*

B. prostrata (prostrate). *fl.* yellow; spikes rarely above 3in. long, oblong or cylindrical, turned up at the ends of the stems. *l.* erect, often above 1ft. long and 1in. to 1½in. broad, divided about half-way to the midrib into broadly ovate or triangular, mostly obtuse lobes, thick, flat, and rigid. Stems prostrate, tomentose. 1824. (B. R. 1572.)

B. serrata (saw-edged). *fl.* red; spikes oblong-cylindrical or rarely globular. *l.* oblong-lanceolate, acute or truncate, deeply serrated, 3in. to 6in. long, ½in. to 1in. broad, coriaceous, flat, hoary or white beneath, tapering to the petioles. *h.* 20ft. (A. B. R. 82.) A very pretty species.

B. speciosa (showy), of Lindley. A synonym of *B. Victoriæ.*

B. spinulosa (slightly spiny). *fl.* yellow, larger than in *B. ericifolia*; spikes ovoid, 2in. to 3in. long, rarely cylindrical and longer. August. *l.* narrow-linear, 1½in. to 3in. long, notched at the end, with a point in the notch, often bordered towards the end with two or three small teeth on either side. *h.* 6ft. 1788. (A. B. R. 457.)

B. undulata (waved). A synonym of *B. æmula.*

B. verticillata (whorled). *fl.* yellow; spikes oblong-cylindrical, 4in. to 8in. long. August. *l.* usually in whorls of four to six, shortly petiolate, oblong-lanceolate or broadly linear, with recurved margins, white beneath, those of the flowering stems 1½in. to 3in. long. *h.* 12ft. 1794. (H. E. F. 96.)

B. Victoriæ (Victoria's). *fl.* yellow; spikes thick, oblong, 3in. to 5in. long. *l.* 8in. to 12in. long, divided more than half-way to the midrib into broad, triangular, acute or acuminate lobes, the larger ones ½in. long and broad. *h.* 12ft. to 15ft. (B. M. 4906.) SYN. *B. speciosa*, of Lindley (B. R. 1728).

BANKSIA (of Domb.). A synonym of **Cuphea** (which *see*).

BANKSIAN ROSES. Somewhat tender Roses from China, for whose introduction we are indebted to Lady Banks.

BAPHORHIZA. A synonym of **Alkanna** (which *see*).

BARBACENIA. To this genus eighteen species have been referred, natives of Brazil, Guiana, and Venezuela.

B. squamata (scaly). A synonym of *Vellozia squamata.*

BARBADOS CEDAR. *See* **Juniperus bermudiana.**

BARBAREA. Yellow Cress. About a score species have been referred to this genus by various authors, but according to Bentham and Hooker not more than six are sufficiently distinct to rank as such; they are broadly distributed over temperate regions, the genus being represented in the British Flora by *B. vulgaris* (St. Barbara's Heath) and several varieties, of which the plant described as *B. præcox* is one. *See* **Cress (American).**

BARBE DE CAPUCIN. *See* **Chicory.**

BARBERRY RUST. This well-known deep yellow Rust, found upon the common Barberry (*B. vulgaris*), the much-grown *Mahonia* (*Berberis*) *Aquifolia*, and allies in spring, is but the Cluster-cup stage of the exceedingly destructive blackish Rust of Wheat and other cereals, and known as **Puccinia graminis,** described and illustrated in Vol. III.

BARBULA. A synonym of **Caryopteris** (which *see*).

BARIDIUS TRINOTATUS. *See* **Potato Insect Pests.**

BARK. This is largely employed as a plunging material for Pine-plants in pots. The tan is placed over a hot-air chamber and made into a bed, in which the pots are plunged up to their rims, the heat in the bed being regulated by the hot-water pipes in the chamber underneath. All plants in pots requiring bottom-heat may be grown in the same manner.

BARK-BEETLES. *See* **Scolytidæ.**

BARKERIA. This genus is now included, by the authors of the "Genera Plantarum," under *Epidendrum*. To the species described on p. 158, Vol. I., the following should be added:

B. Barkeriola (Barkeriola). A synonym of *Epidendrum Barkeriola*.

B. cyclotella (circular). *fl.* very showy, disposed in a terminal raceme; sepals and petals deep magenta; lip white, margined magenta, broad, emarginate. February and March. *l.* distichous, ligulate-oblong, acute. Stems as thick as a quill. Mexico. (W. O. A. iv. 143.)

B. elegans nobilior (nobler). A fine, large-flowered variety, having a blackish-purple spot on the lip. 1886.

FIG. 140. FLOWER OF BARKERIA LINDLEYANA.

B. Lindleyana. This species is one of the most beautiful in the whole genus. See Fig. 140.

B. spectabilis. A showy species, which is at its best about midsummer. See Fig. 141.

Barkeria—*continued.*

FIG. 141. FLOWER OF BARKERIA SPECTABILIS.

B. Vanneriana (Vanner's). *fl.* fine rosy-purple, with a small, whitish disk on the lip, equal in shape to those of *B. Lindleyana*; lip rounded, acute, much like that of *B. Skinneri*. 1885. A fine plant, intermediate in character between the two species named.

BARKHOUSIA RUBRA. A synonym of **Crepis rubra** (which *see*).

BARK LICE. A popular name for Scale Insects.

BARK-WOUNDS. These are of far greater consequence than is usually attached to them by the gardener, especially in the case of dicotyledonous trees. Wounds may result from a number of causes, chief amongst which are careless pruning, hard knocks at felling time, cuts from scythes and mowing-machines, and barking by cattle, deer, and small mammals like mice. Trees so injured are liable to various forms of "rot," some of the most destructive being those for which fungi like *Armillaria mellea* (*Agaricus melleus*) are responsible. Destructive insects like *Sirex gigas* (Horn-tailed Sawfly) and certain Ants also find a ready access by means of wounds.

BARLERIA. This genus embraces about sixty species of herbs and shrubs, mostly natives of Asia and tropical and South Africa, the few American ones being principally Mexican or Columbian. Corolla tube long, the limb of five rounded or ovate lobes. Leaves opposite, entire, the axils often armed with spines. To those described on p. 158, Vol. I., the following should be added. *See also* **Barleriola.**

B. cristata (crested). *fl.* purplish-blue or white; corolla 1½in. long, the lobes ovate, ½in. long; spikes ovate, often compound, dense. July. *l.* oblong or elliptic, acute, 1in. to 4in. long (according to locality, &c.). Branches and leaves yellow-hairy. Sub-tropical. India, 1796. Plant erect or diffuse. (B. M. 1615.)

B. gentianoides (Gentian-like). A synonym of *B. flava*.

B. involucrata (involucred). *fl.* blue; sepals 1in. long, elongated-elliptic; corolla 2in. long, the lobes obovate-elliptic; racemes few-flowered, axillary; bracteoles lanceolate or linear. *l.* elliptic, 4½in. long, 1¾in. broad, narrow at both ends. India. Plant yellow-strigose.

B. i. elata (tall). *fl.* dark blue, 2½in. across. *h.* 6ft. Singapore, 1890. A compact, showy variety.

B. repens (creeping). *fl.* axillary, solitary, sessile or shortly pedicellate; corolla pale, rather dull rosy-red, 2in. long, the tube funnel-shaped, the limb 1½in. in diameter, of five oblong lobes. July. *l.* opposite, appearing as if fascicled, 1in. to 2½in. long, elliptic-ovate or obovate; petioles ⅛in. to ½in. long. Stems 1ft. to 2ft. long, prostrate. Eastern tropical Africa, 1875. (B. M. 6954.)

B. solanifolia (Solanum-leaved) A synonym of *Barleriola solanifolia*.

BARLERIOLA (a diminutive of *Barleria*, to which genus this is related). ORD. *Acanthaceæ*. A small genus (two species) of small, much-branched, stove shrubs, with axillary spines, natives of Cuba and San Dominga. Flowers small, fascicled in the axils, sub-sessile; bracteoles small, subulate. Leaves small. *B. solanifolia* (SYN. *Barleria solanifolia*) has been introduced, but is probably no longer grown.

BARLIA. Included under **Orchis** (which *see*).

BARNADESIA. SYN. *Xenophonta*. Including *Bacazia*. About ten species, all natives of South America, are included in this genus. Flower-heads purple or pink, homogamous, corymbose at the tips of the branches, subradiate, rarely with only one floret; involucral bracts in many series, the outer ones gradually shortening; receptacle flat. Leaves alternate, often fascicled at the axils, entire, three-nerved or penniveined.

BAROSMA. Fifteen species are included in this genus.

B. crenulata (slightly crenate). The correct name of *B. latifolia*. (B. M. 3413.) SYNS. *B. crenata*, *Bucco crenata*, *Diosma latifolia* (L. B. C. 290).

B. scoparia (Broom-like). The correct name of *B. dioica*.

BARRALDEIA. A synonym of **Carallia** (which *see*).

BARRED YELLOW MOTH. *See* **Cidaria.**

BARRINGTONIA. This genus embraces about a score species, natives of tropical Africa, Asia, and Australia. Petals four, rarely five; stamens numerous, in many series. To the species described on p. 159, Vol. I., the following should be added. *See also* **Stravadium** (which is included under this genus by Bentham and Hooker).

B. samoensis (Samoan). *fl.* in long, simple, axillary, pendulous racemes, 2ft. long, with a reddish-brown rachis; petals scarlet, ball-like before expansion, when expanded nearly 1in. long, reflexed; stamens yellow, very numerous, forming a sort of brush 3in. in diameter. May. *l.* sessile, 1ft. to 2ft. long, spreading and decurved, oblanceolate, narrowed to a very short petiole. Polynesia, 1851. A tall, handsome tree. (B. M. 7337.) SYNS. *Butonica samoensis* (T. L. S. ser. ii. Bot. i., p. 75, f. 20-25), *Stravadium insigne* (F. d. S. vii., tt. 654-5).

BARRINGTONIACEÆ. Included under **Myrtaceæ** (which *see*).

BARROTIA. Included under **Pandanus** (which *see*).

BARTHOLINA (named in honour of Thomas Bartholin, a celebrated Danish anatomist and physiologist, born in 1616). ORD. *Orchideæ*. A monotypic genus. The species is a remarkable, small, tuberous, terrestrial Orchid, requiring cool-house treatment and a sandy-loam soil. Propagated by divisions.

B. pectinata (comb-like). Spider Orchid. *fl.* very pale lilac, 2in. to 3in. broad across the numerous spreading, comb-like threads into which each segment of the three-parted lip is divided; sepals erect; petals straight or falcate; scape 3in. to 4in. high, reddish-brown. July. *l.* solitary, orbicular, ½in. to 1in. in diameter, convex, deeply two-lobed, lying flat on the ground. Tuber ovoid, ½in. long. Cape of Good Hope, 1787. (B. M. 7450.)

BARTOLINA. A synonym of **Tridax** (which *see*).

BARTSIA (named by Linnæus in honour of his friend John Bartsch, M.D.). SYN. *Lasiopera*. Including *Eufragia*. ORD. *Scrophularineæ*. A genus comprising about sixty species of mostly hardy, annual or perennial, usually erect herbs, natives of Europe, extra-tropical Asia, North and South Africa, and the mountains of South America. Flowers sessile or shortly pedicellate, the upper ones often forming a spike; calyx five-cleft; corolla tube straight or incurved, the limb bilabiate, the anterior lip with three spreading lobes; stamens four, didynamous. Leaves opposite, the upper floral ones decreasing. Three of the species—*B. alpina*, *B. Odontites*, and *B. viscosa*—are natives of Britain, but none are of any particular value as garden plants.

B. coccinea (scarlet). A synonym of *Castilleja coccinea*.

B. pallida (pale). A synonym of *Castilleja pallida*.

BARWOOD. *See* **Baphia.**

BARYOSMA. A synonym of **Dipteryx** (which *see*).

BASE. That part of a leaf or other organ which is attached to its support.

BASELA. *See* **Basella.**

BASELLA. ORD. *Chenopodiaceæ*. This genus is monotypic, according to Bentham and Hooker, and the correct name of the species, as given in the "Flora of British India," is *B. rubra*.

B. tuberosa (tuberous). A synonym of *Ullucus tuberosus*.

BASILÆA. A synonym of **Eucomis** (which *see*).

BASILEOPHYTA. A synonym of **Fieldia** (which *see*).

BASSIA. SYN. *Dasyaulus*. This genus embraces about eighty species, natives of the East Indies and the Malayan Archipelago.

BASSOVIA. The correct name of **Witheringia** (which *see*).

BAST. *See* **Scirpus lacustris.**

BASTARD CLOVER. *See* **Trifolium hybridum.**

BASTARD CRESS. *See* **Thlaspi.**

BASTARD FEVERFEW. *See* **Parthenium Hysterophorus.**

BASTARD HARE'S-EARS. *See* **Phyllis Nobla.**

BASTARD IRONWOOD. *See* **Trichilia hirta.**

BASTERIA. A synonym of **Berkheya** (which *see*).

BATEMANNIA. According to Bentham and Hooker, this is now a monotypic genus, the only true species being *B. Colleyi*. Several of the species have been transferred to **Zygopetalum** (which *see*).

BATIDEÆ. A monotypic natural order, allied to *Polygonaceæ*, the species being a tropical seaside shrub of botanical interest only.

BATONEUS POPULI. *See* **Populus.**

BATS (*Cheiroptera*) are of especial interest to the farmer and gardener, because they are entirely insect-eaters, so far as the representatives in England are concerned, and therefore of immense benefit. To the naturalist they are likewise of interest, because of the fact that they are the only mammals capable of flight. There is no need here to refer in detail to the peculiar modification of the bones of the fore-limb, or the leathery membrane enabling them to fly. Here we are chiefly concerned with their habits, which are nocturnal or crepuscular, and as before stated, insect-eating. They are exceedingly useful in keeping down some of the worst pests against which gardeners and farmers have to contend—the Cockchafers and June Bugs. Of the first-named a single Bat has been known to take as many as thirteen in succession. Bats also devour enormous quantities of Dipterous insects (Flies) and the smaller and very injurious Moths (*Micro-Lepidoptera*). There are some sixteen species found in this country, although some are rare or local. All, however, should be strictly preserved.

BATSCHIA LONGIFLORA. A synonym of **Lithospermum angustifolium** (which *see*).

BAT'S-WING FERN. *See* **Pteris incisa.**

BAUERA. There are two or three species. *B. humilis* is a variety of *B. rubioides*.

B. rubioides microphylla (small-leaved). *fl.* small, on long and slender pedicels. *l.*, leaflets mostly about ¼in. long. Plant small, slender, and prostrate.

BAUHINIA. As many as 130 species of this genus have been described; they are broadly dispersed over tropical regions. To those described on pp. 161-2, Vol. I., the following should be added:

B. Galpini (Galpin's). *fl.* crimson or scarlet, six to ten in a leaf-opposed raceme; petals 1in. to 1½in. long, with a claw as

Bauhinia—*continued.*

long as the orbicular limb. October. *l.* petiolate, 1in. to 3in. long, orbicular or transversely broadly oblong, broadly two-lobed, pale green. *h.* 5ft. to 10ft. Transvaal, 1895. A half-climbing shrub. (B. M. 7494.)

B. grandiflora (large-flowered). *fl.* pure white, very large, expanding in the night, solitary at the tips of the axillary peduncles. *l.* ovate or cordate at base. Branches spiny. *h.* 15ft. to 20ft. Andes, 1897. Tree. (R. H. 1897, p. 393, f. 126.)

B. variegata. This is figured in B. M. 6818.

B. v. candida (white). *fl.* pure white, large, fragrant. *l.* bright green. *h.* 5ft. Tropical Asia, 1893. A handsome shrub. (B. M. 7312; J. H. 1893, xxvi., p. 277, f. 54.)

BAUMANNIA. A synonym of **Damnacanthus** (which *see*).

BAY-LEAVED WILLOW. *See* **Salix pentandra.**

BEAD-TREE. *See* **Ormosia.**

BEAM-TREE, SWEDISH. *See* **Pyrus intermedia.**

BEAN. BROAD AND LONG-PODDED SORTS. For early sowing the best are: Aquadulce, Bunyard's Exhibition, Dobbie's Champion, and Giant Seville Long-pod. The pods of these are all very long and freely produced, but the Beans are not so good in flavour as the Windsor section, which are a little later than the Long-pods. The following are the best of the Windsor class: Green Windsor, Harlington Windsor, and Improved Broad Windsor.

BEANS, DWARF OR FRENCH. *Sorts.* The following are best for forcing: Emperor William (this is the earliest forcing variety), Ne Plus Ultra, Osborn's Dwarf Prolific, and Williams' Early Prolific. For outside sowing: Best of All, Canadian Wonder, Mammoth Long-podded Negro, and Princess. There are a number of Golden-Butter, or Wax-podded varieties, that so far have not found favour in Britain. The majority of the sorts are dwarf, and, as the name indicates, the pods are of a waxy golden colour, and are cooked whole, the flavour being good if the pods are picked young. The best of this class is Barr's Golden Wax-pod. There is also a Climbing French Bean under the names of Veitch's Climbing French Bean and Sutton's Tender and True. It is earlier than the Scarlet Runners, a great bearer, and of good flavour.

RUNNERS, OR CLIMBING KIDNEY BEANS. *Sorts:* Champion Scarlet, Giant White Czar, Girtford Giant, Hill's Prize Scarlet, Ne Plus Ultra Scarlet, and Sutton's Prize Winner.

BEAN ANTHRACNOSE (*Colletotrichum lindemuthianum*). A well-marked fungus, characterised, as its common name denotes, by a black spotting. In America the disease is very prevalent, and as it may be readily introduced by infected seed the gardener must exercise great care at sowing time. To treat the seed to a fungicide does not seem to be of much avail, judging by the report of Professor Beach, of Iowa, who has made a special study of Bean diseases. Pods, foliage, and stems are all affected, and very young seedlings as well as fully-matured plants. At first the spots are small, but as the disease progresses they increase in size, coalesce, and pit: usually they are edged with red.

Preventive measures consist, according to Professor Beach, in the selection of sound seed (that with dark pits should be rejected), the prompt removal of infected seedlings (the stems should be watched for discoloured patches), and thoroughly spraying with weak Bordeaux Mixture at intervals.

BEAN RUST. *See* **Pea Fungi.**

BEAN, UNDERGROUND. *See* **Voandzeia subterranea.**

BEARD. A tuft of hairs; the awns of Grasses.

BEARDGRASS. *See* **Polypogon.**

BEATSONIA PORTULACIFOLIA. A synonym of **Frankenia portulacifolia** (which *see*).

BEAUCARNEA is the correct name of **Nolina** (which *see*).

BEAUHARNOISIA. A synonym of **Tovomita** (which *see*).

BEAUMONTIA. This genus embraces four species of tall, stove trees or shrubs, natives of the East Indies and the Malayan Archipelago. Flowers white, large, scented, disposed in terminal cymes; calyx five-parted; corolla funnel-shaped, with a short tube and five twisted lobes. Leaves opposite, membranous, often bearing small glands at the axils. To the species described on p. 164, Vol. I., the following variety should be added:

B. grandiflora superba (superb). This is a lovely variety, with white, trumpet-shaped flowers. 1894.

BECIUM. Included under **Ocimum** (which *see*).

BEDDING PLANTS. At one time this term was practically restricted to the ordinary summer occupants of Beds and borders, and a few sub-tropical Bedders. To-day it has a far wider meaning, and Bedding Plants may very well be divided into three groups, according to the season of the year in which they are employed—Spring, Summer, or Autumn. First as to

SUMMER BEDDERS. For these it is now generally recognised that a long-continued display of flowers is very exhausting to the soil, and consequently a good foundation must be laid. The Beds should be well-drained, well-manured, and deeply-worked. The benefits to be derived from deep cultivation are many: it gives a greater degree of openness to the soil, so that the roots can penetrate the more easily, and in dry seasons descend to where the soil is moist, thus escaping, to a greater degree, the evils of drought. In wet seasons, the surplus water also escapes more readily to the drains and subsoil, instead of standing about the roots of the plants and causing their decay. An excellent plan to adopt is to trench the Beds to a depth of 2ft. every second season, and time thus spent will be well repaid by the superior health and beauty of the plants grown.

As to soil, the best for the cultivation of the majority of Bedding Plants is undoubtedly a deep, light loam, resting on a dry subsoil. If the soil is very light and sandy, it is greatly improved by having a quantity of heavy loam incorporated with it; but if it is naturally unsuitable, the best way to remedy the evil is to excavate the original soil to a depth of 2ft., replacing it with, say, a compost of two parts friable loam and one part leaf-mould.

If plants are to be grown in the same ground for several consecutive years, manure must be applied to the soil, or it will soon become exhausted. For this purpose, nothing is better than old hotbed- or well-decomposed cow-manure, on no account using the latter in a fresh state. The dressings are best applied when the Beds are trenched, mixing the manure well with the soil. If trenching is not necessary, the manure might be scattered over the surface and forked well in. In districts where the rainfall is great, as in the neighbourhood of hills, many plants, such as Pelargoniums, produce leaf at the expense of flower. In such localities, the soil should be raised more above the ground-level, and, of course, manure should be more sparingly applied.

The time for planting out depends on the general climate of the district, the position of the garden as to shelter, and the condition of the plants, together with the character of the individual season. It is certainly much better to wait a week or two than to remove plants out of sheltered situations into the open Beds, if there is any fear of cold winds or a night's frost, in which case they would no doubt receive a check sufficient to affect their well-being for the whole season. The usual time for planting out is the end of May or during the month of June. Showery weather is generally chosen for the operation, but should dry weather prevail, planting may commence in June, providing the Beds receive a good watering immediately after.

Bedding Plants—*continued.*

This is preferable to planting when the soil is very wet and sticky, as then it is apt to be pressed into hard lumps. When the plants are in pots, it is best to water them thoroughly overnight, so as to have the balls in a perfectly moist condition by the morning, as when turned out of a pot, and when rather dry, it is almost impossible to get water to enter the ball after the plant has been put in the ground, and it naturally suffers in consequence. If the weather continues dry after planting, liberal waterings should be given at intervals, never allowing the plants to suffer for want of water. The removal of decayed leaves and flowers should be regularly seen to throughout the summer, so that the Beds may at all times present a neat and tidy appearance.

The blending and contrasting of colours is a subject that requires great attention in Bedding arrangements. The harmonising of one colour with another generally produces the most pleasing effect. Thus, by arranging the colours purple, red, pink, salmon, yellow, and white, in the order named, the eye is led gradually from one colour to the other, and perfect harmony prevails. In planting small Beds, however, it is not advisable to introduce too many shades of colour—two, or, at the most, three, will suffice. The most accommodating colour for contrasting with others is white or very light grey, such as is supplied by *Cineraria maritima* or *Cerastium tomentosum*; these plants associate well with all strong colours, and produce striking contrasts.

The gardener of the present day has considerable advantage over his predecessors in the matter of bedding, as the number of beautiful subjects at his disposal is infinite. He has, too, the choice of three distinct styles of Summer Bedding: Ordinary Summer Bedding, Sub-tropical, and Carpet Bedding.

Ordinary Summer Bedding.—Ageratums are useful Bedding plants, blossoming continuously from June till October, or until destroyed by frost; they vary in height from 4in. to 15in. The flowers, which are some shade of blue, or white, are lasting, and retain their colour well. They are excellent plants either for edgings, for small Beds by themselves, or for mixing with Tricolor Pelargoniums, &c.; also as carpeting plants for Fuchsias or other tall-growing subjects. Seeds may be sown in January or February in heat, and the seedlings grown on in small pots, and gradually hardened off ready for planting out in June. They are also propagated readily from cuttings at any season, a little bottom-heat being beneficial.

The dwarf varieties of *A. mexicanum* are the kinds generally used,-such as Cupid, Swanley Blue (often used as an edging plant for Beds of Variegated Pelargoniums), The Zoo, Albiflorum Nanum, Cannell's Dwarf, Imperial Dwarf, Lady Jane, Countess of Stair, Johannas Pfitzer, Le Geant, Perle Bleu, Enfant de Paris, Tapis Blanc, Snowflake, and La Candeur. Several varieties of *Beta vulgaris* are used for Bedding on account of their highly-coloured crimson, dark purple, or bronzy foliage. Dell's Crimson is a well-tried variety; Dracæna-leaved Beet is also good for edgings, growing only 1ft. high, and producing elegant recurved crimson foliage.

The tuberous-rooted Begonias constitute a class of plants admirably adapted for this style of Bedding. They may be grown with less labour and attention than many Bedding Plants, and when in flower it is surprising how they will withstand the ill-effects of wind and heavy rain, and remain one mass of colour until frost puts in an appearance. The shrubby fibrous-rooted section also contributes several species which are now used for Bedding purposes; of these, *B. semperflorens* and its varieties are especially suitable, as they flower with the greatest profusion throughout the whole summer, and also stand the wet weather exceedingly well. The varieties of Begonias suitable for Bedding purposes are now numerous, the following being amongst the best: Worthiana, Erfordi, Vesuvius, Cannell's Scarlet, Baumanni, Queen of Bedders,

Bedding Plants—*continued.*

Ascotensis, Castanæfolia, and Knowsleyana. Most of our nurserymen offer seeds of both single and double varieties, saved from flowers of all shades of colour from white, orange, yellow, and pink, to dark crimson. Seedlings are frequently employed for Bedding, and may be cheaply procured.

Calceolarias are subjects that require good, deep, rich soil, with plenty of manure, the object being to grow them vigorously so as to get healthy green plants, free from insects. The shrubby kinds are generally grown for bedding purposes. These include such well-known forms as Gaine's Yellow, Sultan, and Golden Gem; these grow from 12in. to 18in. in height. *C. amplexicaulis* belongs to the herbaceous section; the plant grows 1½ft. high, and is very good for associating with other taller-growing subjects.

Celosias are now used for Bedding purposes, and very graceful decorative plants they prove to be, with their showy, feathery plumes of flowers. *C. pyramidalis* grows to a height of 18in., and has numerous varieties, usually some shade of yellow or crimson. They are generally described under the name of *C. plumosa*. Sutton's Dwarf is one of the best. Of *C. cristata* (Cockscomb) there are several varieties, most of them with crimson combs. Giant Empress and Vesuvius are both handsome. *Centaurea ragusina* is a valuable Bedding Plant, with broad, silvery-white foliage, for which alone it is used; it is excellent for contrasting with any strong colour, and forms a suitable subject for edgings to Beds of Coleus, Iresines, Perillas, &c. *Cineraria maritima* is a hardy perennial with silvery-white foliage and heads of yellow flowers. The flower-stems must, however, be pinched out as soon as they appear, as it is the silvery foliage that is required. It is largely used for edgings to Beds of Perillas, &c., taking the place of *Centaurea ragusina*. *Coleus Verschaffeltii* is one of the best crimson-leaved plants used for Bedding; it grows from 12in. to 18in. high. It makes very effective Beds when edged with silver- or golden-leaved plants, such as *Cineraria maritima* or Pyrethrum Golden Feather. Taylor's Pet withstands the cold better than *C. Verschaffeltii*.

Fuchsias are largely used in Summer-Bedding arrangements, and very effective plants they prove to be, with their graceful drooping flowers. Some are allowed to assume a bush form, whilst others are kept to a single stem, and grown into pyramids. The dwarf, bushy kinds form excellent Beds, either alone or edged with other dwarf-growing Bedding Plants. Those grown into pyramids make beautiful objects, their drooping branches showing off to advantage. They require a carpeting of Ageratums, Violas, or other dwarf-growing subjects. The varieties of Bedding Fuchsias are very numerous; in fact, almost all of the Fuchsias are sufficiently hardy to stand outside during the summer. Dunrobin Castle is very distinct, and it is suitable for either small Beds, carpeting below taller plants, vases, window-boxes, or for growing into standards. There are several varieties, with richly-coloured or variegated leaves, which are grown extensively for bedding purposes. Amongst these are Cloth of Gold, Sunray, and Meteor.

Gaillardias, as well as being ornamental border-plants, are excellent for Bedding displays. They should be planted rather thinly, so as to allow room for pegging-down the shoots. *G. grandiflora maxima* is one of the best of the perennials. The half-hardy annual varieties, such as *Lorenziana*, *Drummondii* or *picta*, *amblyodon*, &c., are also very effective and useful Bedding Plants, on account of their richly-coloured flowers and the long duration of their flowering period. Gazanias are useful for sunny positions. *G. splendens* is a handsome and much-grown trailer. Heliotropes are always popular for their deliciously fragrant flowers. The dwarf kinds are suitable either for forming Beds by themselves or for

Bedding Plants—*continued.*

carpeting Beds of taller-growing subjects, whilst the vigorous growers are admirable for training into pyramids, carpeting the Beds with other dwarf subjects. Miss Nightingale, although an old variety, is still one of the best for Bedding, while President Garfield and White Lady are also to be recommended.

Two or three Iresines are indispensable for Summer Bedding, on account of their richly-coloured foliage. Like Heliotropes, Iresines are rather tender, and ought not to be planted out until the season is well advanced. To bring their foliage to perfection a warm season, with an abundance of sunshine, is necessary. *I. Herbstii*, *I. aureo-reticulata*, and *I. Lindeni* are excellent; the last forms a fine edging plant to Beds of Pelargoniums, &c.

The named varieties of Lantana, with their large Verbena-like heads of richly-coloured flowers, produced abundantly during the whole summer, are charming subjects for Beds. They are as easy to cultivate as Pelargoniums, and may be used either in Beds by themselves, or as carpeting plants for tall-growing Fuchsias, &c.; or they may be trained as standards. Drap d'Or is unequalled for Bedding, while Don Calmet is very floriferous. The predominating colour amongst the dwarf-growing Lobelias is blue, a colour which is rather rare amongst the ordinary run of Bedding Plants. To this, and to their dwarf compact habit, may be attributed the reason of their universal adoption for Bedding purposes, and especially as edgings to Beds of taller subjects.

Lobelia Erinus is the species from which most of our dwarf Bedding varieties have sprung. *L. speciosa*, *L. compacta*, *L. pumila magnifica*, *L. ramosa*, Cobalt Blue, Swanley Blue, Crystal Palace, and Emperor William are amongst the best dwarf kinds. Of the taller-growing kinds *L. cardinalis*, *L. fulgens* or *L. splendens*, Queen Victoria, and Firefly, in mild districts, prove hardy enough to stand the winter outside with a light covering of ashes, &c., though it is always best to lift and store them in a dry shed, starting them into growth again in spring.

In the whole range of Bedding Plants it would be difficult to name a more popular favourite than the Zonal Pelargonium. There are ordinary Zonals, Golden-bronzed Zonals (Model, Golden Harry Hieover, and Bronze Queen), Yellow-leaved (Crystal Palace Gem and Robert Fish, with zoneless leaves), Golden Tricolors, Silver Tricolors, White-Edged (these fine-foliaged varieties are generally grown for the sake of their leaves, and on this account are seldom allowed to flower), and Ivy-leaved. These last are suitable for covering trellises and for growing in vases, where their long, trailing growths, hanging over the sides, show off to advantage. They are rather more tender than the Zonal kinds, and require to be kept a little warmer during the winter.

Perilla nankinensis is a most useful Bedder, and is generally employed for edgings or for mixing with silver-leaved plants, on account of its dark purplish foliage. Petunias are very showy and popular subjects when grown in masses in a sunny position and fairly rich soil. They are very effective when trained over hoops, fences, and trellises, as well as disposed over tree-stumps. *Phlox Drummondi* is a plant which cannot be passed by unnoticed, as for filling small Beds, or for mixing with taller-growing subjects, it is superb. Pyrethrum Golden Feather is a well-known, free-growing Bedding Plant, suitable for edgings, &c. It has been styled "the gardener's friend," and it certainly is a treasure to him, for it can always be relied upon, and is always in season. In spring the plants look like masses of gold, and in summer they light up the whole garden, and harmonise with everything.

Verbenas rank amongst the showiest of our Summer Bedding subjects; they are very effective in Beds, especially when mixed with some contrasting colour,

Bedding Plants—*continued.*

such as is supplied by the Silver-Leaved Pelargoniums. There are also several named varieties which are very useful for Bedding purposes, such as Crimson King, Purple King, and *V. Melindres splendens.*

Sub-Tropical Bedding.—The introduction of large-foliaged, stately, sub-tropical plants into our flower-gardens during the summer months has been arranged so as to enable us, as it were, to obtain faint glimpses of the grandeur of tropical vegetation. In this style of Bedding any sub-tropical plant may be used, providing it is sufficiently robust in constitution to withstand the variations of our changeable climate. Many of the plants used are of a tender nature, and only suitable for standing outside during the hottest part of the summer; but there are others which are hardy enough to withstand an ordinary English winter—in the South of England, at any rate. To this latter group belong such plants as *Gynerium argenteum* (Pampas Grass), *Arundo Donax*, *Gunnera scabra* and *G. manicata*, *Chamærops humilis*, *C. Fortunei (Trachycarpus excelsus)*, and the Bamboos. These stately subjects are suitable for planting either as single specimens about the lawn or in groups in sheltered positions. The Gunneras require damp situations, preferably near the banks of lakes or streams, and when the foliage dies down in the late autumn, the crowns should be protected from frost by having a quantity of dry leaves thrown over them to the depth of 12in. or 18in. As the Gunneras start into growth early in the season, the winter covering should be removed before the young leaves have made much progress, otherwise they will be damaged during the operation. When in the young state the leaves are very tender, and preparation must be made for covering up the plants if any signs of frost appear.

Returning to the non-permanent Sub-tropical Bedders, there are two distinct groups—to the one belong the Agaves, the tender Yuccas, Dracænas, Musas, Tree-Ferns, and several of the Palms—plants generally of slow growth, which are kept in pots or tubs, and plunged outside during the summer, and have to be removed to the greenhouse for the winter; these present a fine appearance, giving to the garden a tropical aspect. One of the most essential points in the culture of Musas, Tree-Ferns, and, in fact, of all tender large-foliaged plants grown outside, is that of shelter, as if exposed to high winds the leaves get torn to shreds, and the plants are thereby disfigured, and look unsightly objects in the flower-garden. It is therefore imperative that a sheltered position should be chosen for this phase of Sub-tropical Bedding. For more exposed situations, and for terrace gardens, the Agaves and Yuccas are amongst the best of stately-foliaged plants, as the leaves are not liable to be damaged by the wind, and the plants themselves are more in accordance with their surroundings. As this class of plants require a considerable amount of room for their accommodation in winter, it is evident that Sub-tropical Bedding cannot be carried out to any extent, except in very large establishments, where plenty of room is at command during winter.

To the other group belong the Cannas, the tubers of which may be taken up in the late autumn, and after being dried, stored away for the winter in a shed or other suitable structure, where they are out of the reach of frost. With this group may be included numerous robust-growing annuals that are readily raised from seed sown in February, and which make quite large plants, if grown well. Of these the Castor-oil, Solanums, and Tobacco plants are examples. With regard to planting out, the second week in June is about as early as it is safe to plant out Castor-oil plants and other soft-wooded subjects grown from seed. It is preferable to have stout young plants, well-rooted, and carefully hardened off, as they succeed much better than larger specimens grown on in a high temperature and insufficiently hardened off; in fact,

Bedding Plants—*continued.*

this point constitutes one of the elements of success in the management of these large-foliaged plants.

Besides the plants mentioned elsewhere, numerous others may be used for Sub-tropical Bedding, such as Carlina, Aloe, Sumach, Fatsia (Aralia), Funkia, Eryngium, Rheum, Heracleum, Bocconia, Cassia, &c. Also available are some of the ordinary Summer Bedding plants, such as Coleus, Iresines, Perillas, Beet, Centaureas, Cinerarias, &c., which are used either for mixing with the sub-tropical plants in the Beds, or as edgings for the same. Carpeting plants, such as the Alternantheras, are also used, and when judiciously arranged, give a finished appearance to the Beds. In fact, the modes of arranging the plants at command are endless; yet the same object is kept in view, viz., an attractive and effective display, avoiding all formality, but at the same time aiming at a neat, symmetrical appearance when completed.

Abutilons, if planted outside in June, will flower freely throughout the summer. Several ornamental-foliaged varieties are grown for Bedding purposes, *A. Thomsoni*, *A. megapotamicum* (*A. vexillarium*), and the variety *variegatum*, and *A. Sellowianum marmoratum*, being very attractive. *Albizzia* (*Acacia*) *lophantha* is a handsome plant for mixed Sub-tropical Bedding; it is of quick growth, and produces an abundance of graceful bipinnate leaves. Cannas are splendid plants, admirably adapted either for massing in Beds by themselves or for mixing amongst other subjects; they are of stately growth. Numerous hybrids are now grown, most of which have been reared by M. Crozy, of Lyons. Madame Crozy, Paul Bert, and Ménélik are very effective. Daturas are handsome massive-foliaged plants with large trumpet-shaped flowers, and are much admired. The best kinds are *D. ceratocaula*, *D. Cornucopiæ*, and *D. meteloides* (*D. Wrightii*).

Eucalyptus globulus is a fast-growing subject, having leaves of a peculiar glaucous hue. The well-known *Ficus elastica* is suitable either for mixing in groups of tall-growing plants, or for planting amongst dwarf carpeting plants. *Grevillea robusta* is a most graceful plant, with fern-like foliage. *Humea elegans*, *Lavatera arborea variegata*, *Melianthus major*, Nicotianas, Ricinus, several of the strong-growing Solanums, like *S. marginatum*, *S. robustum*, and *S. Warscewiczii*, the bold Wigandias, *W. macrophylla* (*W. caracasana*), *W. urens*, and *W. Vigieri* may be effectively used.

Carpet Bedding.—This style of Summer Bedding is gradually disappearing. Carpet Bedding, as practised years ago, consisted of the planting of Beds in geometrical form with various dwarf coloured-foliaged plants, the object being to imitate fancy designs, such as were found on Turkey carpets, &c., and to work them out in different colours. The dwarf plants so used needed constant attention with regard to pinching and keeping them within their allotted space, or the design would quickly be spoiled by the strong growers running into and smothering the weaker subjects, and the Bed present the appearance of disorder and neglect. At the present day a decided improvement in the art of Carpet Bedding is to be seen in many of our large public parks and other places: this consists of a freer use of tall, graceful subjects, suitable for associating with the typical Carpet Bedding plants; and in this way many pleasing effects are produced.

Carpet Bedding should not be done until about the middle of June. The Beds ought to have been dug over about a fortnight previously and left to solidify; they will then only require to be made moderately firm, and to have the surface-soil raked smooth and even at the time of planting. The design is then transferred to the Beds by drawing lines in the soil. Circles may easily be drawn by fixing a stick firmly in the centre of the Bed, and looping a piece of string over it; then by attaching another stick to the string at the distance required, the circles may be drawn correctly. When all the lines are drawn they are traced with a little dry silver-sand, so as to make them more distinct for the operator. Planting then commences: the tall dot-plants are put in first, then the leading lines, and afterwards the intermediate spaces or panels are filled in.

Bedding Plants—*continued.*

As the majority of the plants are very small, and have to be planted quite close together, a narrow, pointed trowel is used; or the trowel may be dispensed with altogether and the work done with the fingers. The soil is made fairly firm around them, and a good watering given immediately after planting. If dry, hot weather sets in, the Beds must have occasional waterings throughout the summer. The dwarf plants will also require pinching at frequent intervals so as to keep them dwarf.

Irrespective of the popular carpeting plants mentioned below, there are numerous others belonging to the Sub-tropical and ordinary Summer Bedding class that are available either as dot or centre plants in connection with Carpet Bedding. Of these, the following may be mentioned: *Abutilon Thomsoni*, Agaves, *Fatsia* (*Aralia*) *japonica*, Centaureas, Coleus, *Dracæna australis*, Iresines, Perillas, and Yuccas.

The following list of plants includes the best of those most commonly grown for Carpet Bedding. The Saxifrages, Sempervivums, and Echeverias may be allowed to flower if it is desired; but generally the flowers are pinched out. All the other plants are grown exclusively for their foliage.

Alternantheras are largely used for filling in panels, divisional lines, &c. Several species and varieties are grown: *A. amabilis*, *A. amœna*, *A. versicolor*, *A. paronychioides*, *A. aurea nana*, *A. magnifica*, *A. major*, *A. m. aurea*, and *A. rosea nana*. *Antennaria tomentosa* or *A. candida* is largely used for edgings or divisional lines. *Calocephalus* (*Leucophyton* or *Leucophyta*) *Brownii* is used for filling in panels, &c. *Centaurea ragusina compacta* is very useful for Ribbon Bedding, a style which consists of filling a border the whole length with rows of plants, each row being of a different shade of colour, so that the border, especially when viewed from a distance, presents the appearance of a ribbon. It is also used as a dot-plant. *Cerastium tomentosum* is used for edgings, for filling in panels, &c. *Chamæpeuce Casabonæ* and *diacantha* are largely used as dot plants in connection with Carpet Bedding, as well as for sub-tropical work. Echeverias are used for edgings, divisional lines, &c.; the flower-stems vary from 6in. to 12in. in height. *E. agavoides*, *E. metallica*, *E. Peacockii*, and *E. secunda glauca* are those most commonly grown. *Herniaria glabra* is a creeping plant of neat, close habit, suitable for filling in the groundwork. *Kleinia repens* is a succulent, used for divisional lines. *Mentha Pulegium gibraltarica* is a useful groundwork plant, very effective when surrounded with brighter colours. *Mesembryanthemum cordifolium variegatum* is used for filling in panels, &c. *Pachyphytum bracteosum* is an attractive succulent, forming a useful dot plant, or for dividing lines. *Sagina pilifera aurea*, or *glabra aurea*, is an excellent subject for filling in panels. *Santolina incana* is useful as a dot plant. Saxifragas are excellent carpeting plants, for either Summer or Spring Bedding. Sedums, like *S. glaucum* and *S. lydium*, are used for panels. Sempervivums are very useful for forming divisional lines, &c. *Stellaria graminea aurea* is a bright carpeting plant for dividing lines or for filling in panels.

The designs furnished will give the gardener a fair idea of how the above-mentioned plants may be utilised in the present system of Carpet Bedding. As individual tastes differ, however, so the arrangements of the dwarf plants may be altered accordingly, and the tall plants may or may not be used, as fancy dictates. If the Beds are small, it will not be advisable to include too many dot-plants, but

Bedding Plants—*continued.*

hard-and-fast rules cannot be laid down, and in such cases the planter must use his own judgment. In some Beds it is well to have the central portion raised from 6in. to 12in. above the outside portion, the edge being planted with Echeverias or *Sempervivum tabulæforme*. This may easily be done in the Beds H and I (Figs. 149 and 150), and will greatly enhance their beauty.

FIG. 142. DESIGN FOR CARPET BED (A).

In Bed A (Fig. 142), No. 1 might have a centre plant of *Grevillea robusta*, and be carpeted with *Echeveria Peacockii*; No. 2 with *Sempervivum montanum*; No. 3 with *Leucophyta Brownii*; No. 4 with *Alternanthera versicolor*, having a dot-plant of Grevillea at the centre of each panel; No. 5 with *Alt. paronychioides*; No. 6 with *Alt. aurea nana*; No. 7 with *Alt. major*; No. 8 a dot-plant of *Santolina incana*, carpeted with *Alternanthera amabilis*; No. 9 should be filled in with *Mesembryanthemum cordifolium variegatum*; and No. 10 with *Alternanthera magnifica*.

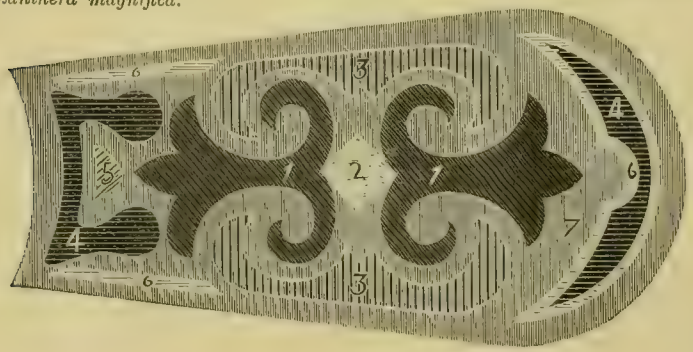

FIG. 143. DESIGN FOR CARPET BED (B).

Bedding Plants—*continued.*

In Bed B (Fig. 143), the panels numbered 1 might be filled in with *Alternanthera amœna*, and have a small plant of *Albizzia (Acacia) lophantha* inserted near the end furthest away from the centre of the bed; No. 2 would look well with a centre plant of *Cordyline (Dracæna) australis*, or any other tall, graceful-foliaged plant, carpeted with *Echeveria secunda glauca* or *Leucophyta Brownii*; panels numbered 3 might have dot-plants of Dracænas at their centres, and also one near each end, carpeted with *Alternanthera magnifica*; panels marked 4 with *Alt. versicolor* and a dot-plant or two of *Echeveria Peacockii*; No. 5 with *Alt. rosea nana*; and the portions marked 6 with *Alt. aurea nana*; the groundwork (No. 7) might then be filled in with *Herniaria glabra* or with one of the Mossy Saxifrages.

In Bed C (Fig. 141), No. 1 should be filled in with Mesembryanthemum, and have a plant of *Albizzia lophantha* at the centre of the heart; No. 2 with *Alternanthera major aurea*; No. 3 with *Alt. magnifica*, having a dot-plant of Acacia in the centre of each; No. 4 with *Sagina (Spergula) pilifera aurea*; those outside the panels numbered 6 should each have a plant of Chamæpeuce in the centre; No. 5 should be filled in with *Leucophyta Brownii* or *Antennaria tomentosa*, having a dot-plant of Acacia in the centre: No. 6 with *Pachyphytum bracteosum*, also having an Acacia in the centre if the bed is made large enough to allow of it without overcrowding; the groundwork (No. 7) should consist of Herniaria or one of the Sedums.

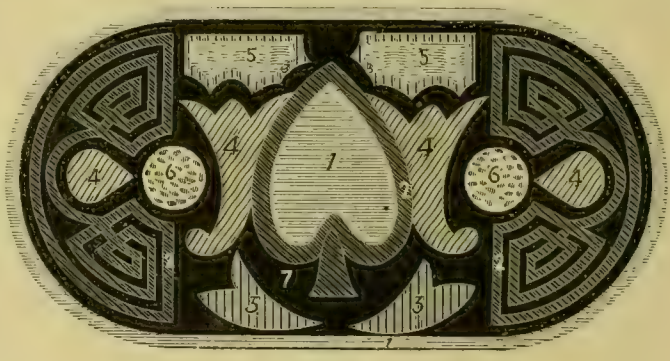

FIG. 144. DESIGN FOR CARPET BED (C).

In Bed D (Fig. 145), No. 1 might be filled with *Alternanthera magnifica*; No. 2 with *Alt. versicolor*; No. 3 with *Alt. amœna*; Nos. 2 and 3 should also have a centre plant of *Ficus elastica*, *Fatsia japonica*, or a small Palm; No. 4 should be filled in with specimen dot-plants of Coleus, Perilla, Iresine, Centaurea, Santolina, &c., planted in opposite pairs; No. 5 should be filled with Mesembryanthemum, and lined with *Kleinia repens*; No. 6 with *Sagina pilifera aurea*; No. 7 with Mentha; and the groundwork (No. 8) with *Antennaria tomentosa*, *Sedum glaucum*, or *Sedum lydium*.

In Bed E (Fig. 146), No. 1 might be filled in with *Alternanthera major*, and No. 2 with *Alt. major aurea* or *Stellaria*

CHRYSANTHEMUMS:

1.—Yellow La Croix. 2.—Alice Carter. 3.—N.C.S. Jubilee.

Bedding Plants—*continued.*

graminea aurea; a row of from three to five plants of Chamæpeuce might be placed along the middle of Nos. 1 and 2. No. 3 might be planted with *Kleinia repens*, No. 4 with *Alternanthera amœna*, and No. 5 with *Alt. amabilis* or *Alt. magnifica*, having centre plants of Chamæpeuce. The groundwork (No. 6) might be filled with Mentha, Herniaria, Antennaria, or one of the Sedums. If the bed is of sufficient size, *Eucalyptus globulus* might be substituted for the plants of Chamæpeuce.

In Bed F (Fig. 147), panel No. 1 might be filled with *Alternanthera amœna*; No. 2 with *Echeveria secunda glauca* or *E. agavoides*; No. 3 with *Cerastium tomentosum* or *Sagina pilifera aurea*; No. 4 with *Iresine Lindeni*; No. 5 with *Alternanthera major*; No. 6 with *Alt. aurea nana*; and the groundwork (No. 7) with Mesembryanthemum. If dot-plants are required for this Bed, specimens of Dracæna, Grevillea, or *Albizzia lophantha* might be inserted in the centre of Nos. 1, 4, 5, and 6.

In Bed G (Fig. 148), No. 1 should consist of a small specimen Yucca or Dracæna; No. 2, *Echeveria Peacockii*, edged with *Sempervivum montanum*; No. 3, *Alternanthera amœna*; No. 4, *Pachyphytum bracteosum* or *Leucophyta Brownii*; No. 5, *Antennaria tomentosa* or *Alternanthera major aurea*; No. 6, *Alternanthera versicolor*; No. 7, Mesembryanthemum; No. 8, Mentha; No. 9 with *Pyrethrum* Golden Feather. The centres of Nos. 4 and 5 should consist of small specimen Palms; whilst the centres of the panels 7 and 8 might, with advantage, have plants of Coleus, Perilla, or Iresine inserted. All the panels should be raised and bevelled off, the central cross of *Echeveria Peacockii* being raised still further, and the *S. montanum* planted on the sides. A nice plant of Chamæpeuce may be planted in the centre of the panels No. 6.

In Bed H (Fig. 149), No. 1 might be filled with *Kleinia repens*, having a centre plant of *Fatsia japonica*; No. 2 with *Alternanthera versicolor*; No. 3 with *Alt. paronychioides*, having a small plant of *Ficus elastica* at each of the four corners; No. 4 with Mentha; No. 5 with *Echeveria secunda glauca*; No. 6 with *Alternanthera amœna*, having centre dot-plants of *Centaurea ragusina compacta* or *Santolina incana*; No. 7 with *Alternanthera aurea nana*; No. 8 with *Echeveria metallica*; No. 9 with *Cerastium tomentosum*, having dot-plants of Iresine in the centre; No. 10 with Mesembryanthemum; No. 11 with *Alternanthera major aurea*, having dot-plants of Chamæpeuce; No. 12 with Antennaria or Spergula, interspersed with *Sempervivum tabulæforme* or *S. triste*. The beauty of the Bed will be improved if the whole of the central portion from No. 5 inwards is raised about 8in., and the Echeveria planted in a double row on the edge.

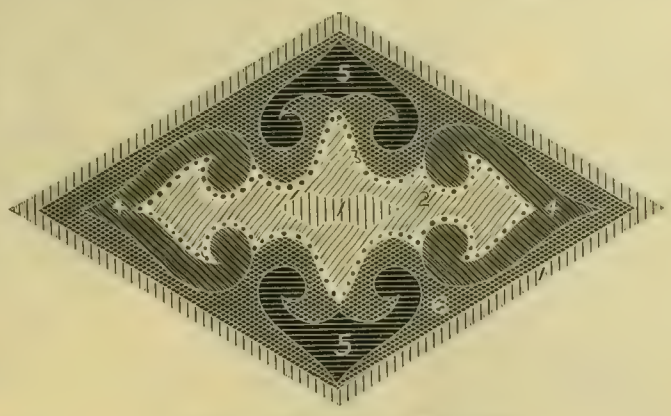

FIG. 146. DESIGN FOR CARPET BED (E).

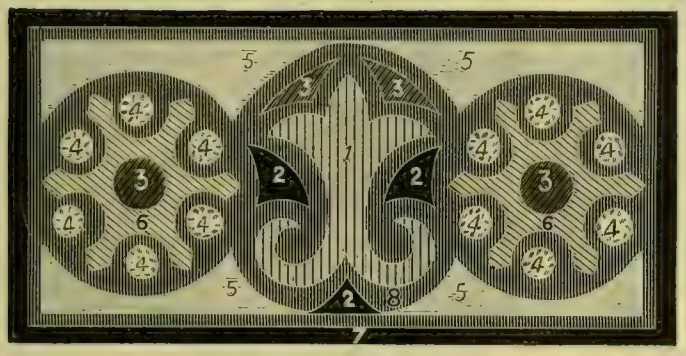

FIG. 145. DESIGN FOR CARPET BED (D).

In Bed I (Fig. 150), No. 1 should have a centre plant of *Grevillea robusta* or *Eucalyptus globulus*, and be carpeted with *Alternanthera magnifica* or *Alt. versicolor*; No. 2 would be best filled in with Mesembryanthemum or *Sagina pilifera aurea*; No. 3 with Herniaria or Mentha; No. 4 with *Alternanthera major*; No. 5 with *Alt. rosea nana*; and No. 6 with *Alt. aurea nana*. The three outside panels numbered 5, and also the three outermost numbered 6, might each have a specimen plant of Grevillea in the centre; or those numbered 5 would look well with a plant of Chamæpeuce in the centre, and those numbered 6 with one of Coleus.

In Bed J (Fig. 151), No. 1 might be filled in with

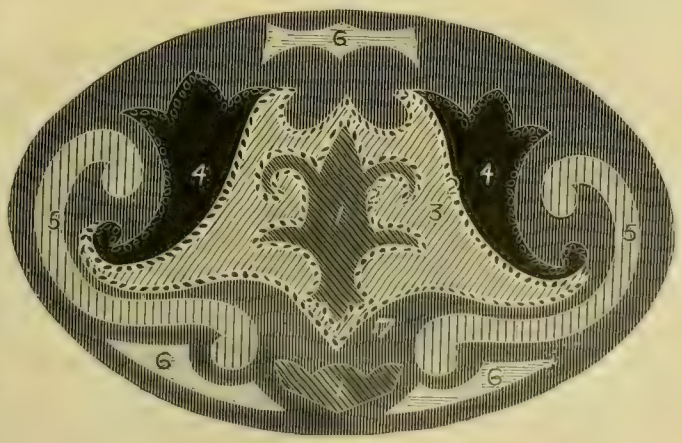

FIG. 147. DESIGN FOR CARPET BED (F).

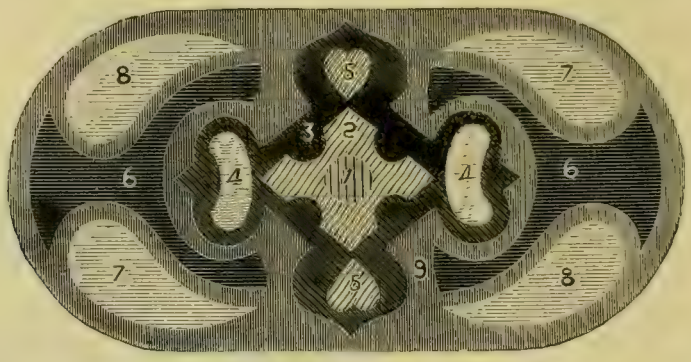

FIG. 148. DESIGN FOR CARPET BED (G)

Bedding Plants *continued.*

Iresine or *Alternanthera paronychioides*; No. 2 with *Echeveria secunda glauca*; No. 3 with Mesembryanthemum; the panels numbered 4 might be planted with *Alternanthera amœna*, and have a plant of *Abutilon Thompsoni* in the round portions at each end of the panels.

FIG. 152. DESIGN FOR CARPET BED (K).

Bedding Plants—*continued.*

In Bed K (Fig. 152), panel No. 1 might be planted with *Alternanthera aurea*, having a centre plant of Perilla; No. 2 with *Alt. amœna*; while the top and the two lower No. 2 panels might each have a centre plant of Chamæpeuce; No. 3 with *Alternanthera versicolor*, having centre

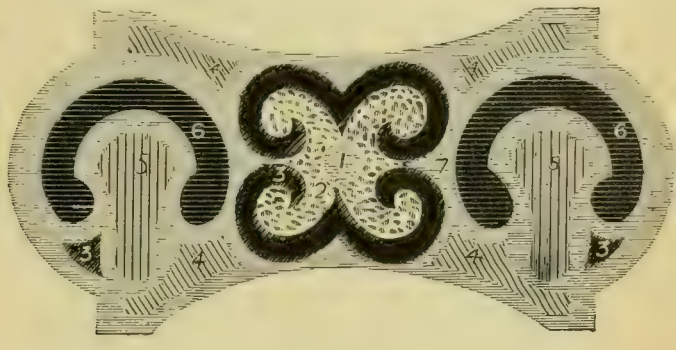

FIG. 153. DESIGN FOR CARPET BED (L).

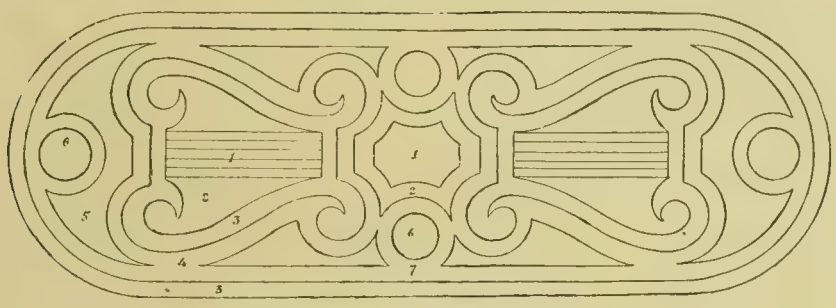

FIG. 154. DESIGN FOR CARPET BED (M).

FIG. 155. DESIGN FOR CARPET BED—FRENCH (N).

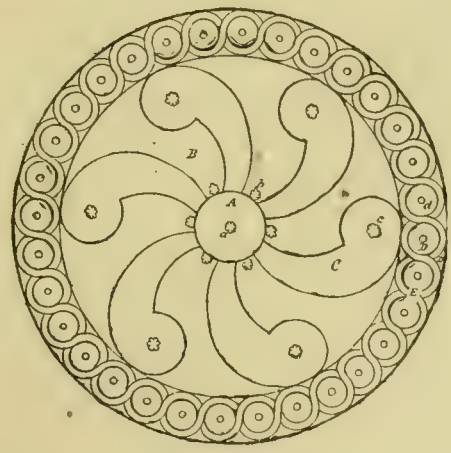

FIG. 156. DESIGN FOR CARPET BED (FRENCH—AFTER MANNRENÉ) (O).

The number 5's should each have a centre plant of Abutilon, and be carpeted with *Pachyphytum bracteosum*; No. 6 with *Alternanthera versicolor*; No. 7 with *Alt. major aurea* or *Alt. aurea nana*; the groundwork (No. 8) being carpeted with Mentha, Herniaria, Antennaria, or *Sedum glaucum*.

plants of Centaurea; No. 4 with *Alternanthera magnifica*; No. 5 with specimen dot-plants of Perilla; the groundwork (No. 6) might be filled in with Mentha, Herniaria, Antennaria, or Stellaria.

In Bed L (Fig. 153), No. 1 should be planted with a specimen Dracæna or Aralia; No. 2 with *Echeveria*

Bedding Plants—*continued.*

Peacockii; No. 3 with *Alternanthera amœna*; No. 4 with *Alt. aurea nana*, having centre plants of Iresine; No. 5 with *Alt. magnifica* or *Alt. rosea nana*, having centre plants of *Albizzia lophantha*; No. 6 with *Alternanthera versicolor* or *Alt. major*; the groundwork (No. 7) with Mentha, Mesembryanthemum, Antennaria, Herniaria, or Sedum. The central panel might be nicely moulded from a slightly-raised centre to the edges.

In Bed M (Fig. 154), No. 1 might be filled with *Pachyphytum bracteosum*; No. 2 with *Alternanthera paronychioides major*; No. 3 with *Alt. p. m. aurea*; No. 4 with *Herniaria glabra*; No. 5 with *Alternanthera amœna*; No. 6 with *Mesembryanthemum cordifolium variegatum*; and No. 7 with *Pachyphytum roseum*.

In Bed N (Fig. 155), A should have a centre plant of *Yucca aloifolia*, surrounded with *Cineraria maritima candidissima* (B); C should be planted with *Ageratum Wendlandii*; D, with Coleus Golden Gem; E, with *Ageratum mexicanum nanum*; F, with *Lobelia Erinus compacta*; G, with *Antennaria dioica*; H, with *Alternanthera paronychioides*; and I, with *Ageratum mexicanum nanum*.

In Bed O (Fig. 156) there should be a central plant of *Livistona australis* at *a*, surrounded by *Amarantus melancholicus ruberrimus* (A); at *b*, *Fatsia papyrifera*; at *c*, *Dracæna Draco*; and at *d*, *Echeveria gibbiflora*; B should be filled with *Tagetes* Legion of Honour; C, with *Ageratum mexicanum nanum*; D, with *Iresine Lindenii*; and E, with *Lobelia Erinus compacta*.

FIG. 157. DESIGN FOR CARPET BED (P).

Fig. 157 (P) may be utilised for either a Carpet or a Decorative Bed. If the former, there should be a *Phœnix dactylifera* as a central plant at A, surrounded by *Begonia Worthiana*; *a* should be filled with Lobelia Cobalt Blue; *b*, with *Alternanthera paronychioides*; *c*, with *Mesembryanthemum cordifolium variegatum*; *d*, with *Echeveria metallica*; *e*, with *Mentha Pulegium gibraltaricum*; *f*, with *Dracæna gracilis*; *g*, with *Alternanthera amœna*; *h*, with *Pyrethrum aureum selaginoides*; *i*, with *Cerastium tomentosum*.

Bedding Plants—*continued.*

A pretty Decorative Bed for P could be composed as follows: A, *Yucca filamentosa*; *a*, Pelargonium Black Douglas; *b*, Pelargonium Harry Cox; *c*, Pelargonium Vesuvius; *d*, Lobelia Blue Beauty; *e*, Pyrethrum Golden Feather; *f*, *Begonia Worthiana*; *g*, *Alternanthera paronychioides magnifica*; *h*, *Iresine Lindenii*; *i*, *Mesembryanthemum cordifolium variegatum*.

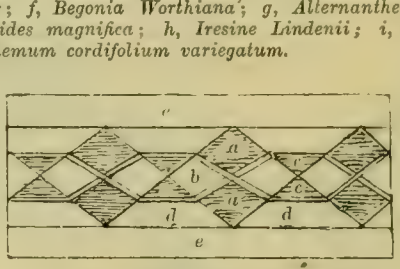

FIG. 158. DESIGN FOR CARPET BED (Q).

At Bed Q (Fig. 158), *a* may be filled with *Echeveria secunda*; *b*, with *Sempervivum montanum*; *c*, with *Sempervivum calcareum*; *d*, with *Echeveria secunda*; and *e*, with *Oxalis tropæoloides* (of gardens).

Spring Bedding consists in planting Beds in the autumn with bulbs and hardy herbaceous subjects for an early spring display. When the Summer Bedders have lost their beauty, and no longer present an attractive appearance, they are removed—those that are required for next season's display are placed in their winter quarters, whilst the others, such as Pelargoniums, from which an ample stock of cuttings have been procured, are thrown away. It is then usual to dig over the Beds, and plant immediately with the spring-flowering subjects; this is generally done in September and October—the sooner the better—so that the plants may be well established before winter sets in.

Bulbs play a very important part in the decoration of the Beds in spring. For this purpose they should be procured as soon as convenient in the autumn, those known as "Dutch bulbs" being inserted as soon as they arrive from the Continent, if the best results are to be obtained. They answer splendidly either grown in Beds by themselves or mixed with other spring-flowering subjects, such as Polyanthuses, &c. After flowering they must be removed, so as to make room for the Summer Bedders, and this very often, if not always, has to be done before the foliage has died down, in which case they must be laid close together in Beds in the reserve garden or in damp ashes, &c., to thoroughly ripen off.

The varieties of these subjects are very numerous, and it will not be necessary to mention them here, as large quantities may be procured from our various seedsmen, either in named varieties or in mixed sorts. The catalogues generally give the colour of each kind.

Hardy annuals are also used for Spring Bedding; these are obtained from seed sown in July or August in the reserve garden, transplanting the seedlings when large enough, so as to make fine strong plants for transferring to their permanent positions in September and October.

The hardy perennials, when removed from the Beds in spring, are planted in the reserve garden, there to have every attention as regards watering, weeding, &c., until required for transferring to their flowering quarters again

Bedding Plants—*continued.*

in the autumn. Propagation is generally effected by division of the old plants when transplanting, in either the spring or the autumn. Large numbers may also be raised from cuttings or from seeds.

The arrangement of the plants in the Beds is an item which demands attention, if good results are to be obtained; but in this matter each individual has his own particular fancy, and excellent effects are produced by blending and contrasting colours in a variety of ways. It is a mistake to aim at too much in a single Bed, two or three colours being quite sufficient to produce a charming display. In planting round Beds it is a general rule to do so in circles, using first one colour and then another, alternately, say, a circle of white Arabis, then one of yellow Alyssum, and then one of the blue Myosotis. Excellent effect is, however, obtained by filling Beds with distinct families of plants; for instance, a Bed filled with mixed Polyanthuses in various shades of colour proves very attractive; Wallflowers might also be used in a similar way.

The following are the most important of the spring-flowering subjects suitable for Bedding:

Alyssum saxatile compactum contrasts charmingly with the white Arabis and blue Aubrietia; *Anemone blanda, A. apennina*, and *A. coronaria; Arabis albida; Aubrietia deltoidea, A. Campbelli, A. græca*, and *A. Leichtlinii;* Daisies; Erysimums; *Iberis sempervirens, I. s. Garrexiana*, and *I. gibraltarica; Myosotis dissitiflora; Phlox amœna* and *P. subulata; Silene pendula, S. compacta*, Snow King, and Amelia; and Wallflowers.

Winter Bedding is very little practised, it usually being the custom to fill the Beds with bulbs and other hardy subjects in the autumn for spring display, and the consequence is that throughout the dull dark days of winter the Beds present a very bare and uninteresting appearance. When they are at some distance from the house, or in parts of the garden little frequented in winter, this prevailing bareness does not matter much; but when the Beds are on the lawn immediately in front of the house, as is often the case, it is evident that they ought to be filled with plants of some sort, so as to make a show during the winter.

Taking into consideration that the Beds are required for summer occupants, and therefore cannot be planted with permanent subjects, it is obvious that those selected to fulfil the requirements of Winter Bedding must be such that will bear transplanting well, and at the same time they must be perfectly hardy. The plants that possess these essentials are undoubtedly our hardy evergreen shrubs and small Conifers, and seeing what a wealth of these subjects are now in our possession, it is a pity that they are not more used for the decoration of Beds in winter. Of course, if Spring Bedding is to be adopted in its entirety, Winter Bedding is impossible; but why not come to a compromise between the two systems, and have a little of both? For instance, some of the Beds might be filled with hardy evergreens, and the remainder with Spring Bedding Plants; the effect would then be materially improved for during the winter the evergreens would enliven the scene to a certain extent, whilst in the spring, when they were making their new growth, and the Spring Bedders were at the zenith of their beauty, the effect would be charming. If the evergreens are grown in pots for this purpose, it is only necessary to plunge them in the Beds in the autumn, and to remove them in the spring. The best place for them during the summer is in the reserve garden, plunging them in soil or ashes, and taking care that they do not suffer for want of water. Growing in pots is a good method, for, their roots being restricted, they do not grow so freely, and they are, therefore, available for service for a much longer time than those planted out.

If the evergreens, however, are planted out in the Beds, the greatest care must be taken in planting and replanting,

Bedding Plants—*continued.*

or they will suffer by the somewhat harsh treatment to which they are subjected by being lifted twice a year. They should be planted in the late autumn and removed again about April. It is not advisable to defer lifting and transferring to their summer quarters later than is absolutely necessary, as the plants ought to be established before the hot, scorching days of summer set in. The best plan is to plant them carefully in a somewhat shaded border in the reserve garden, the only attention necessary during the summer being that of watering, keeping clean, &c.

The following list of Conifers includes most of those suitable for Winter Bedding: *Cryptomeria japonica elegans* and variety *nana; Cupressus nootkatensis* (*Thuyopsis borealis*) and variety *compacta; Cupressus Lawsoniana* and its many varieties, including *argentea, compacta, nana, albo-picta*, &c.; *Cupressus obtusa* and varieties *aurea, nana-compacta*, &c.; *Cupressus pissifera* and varieties *plumosa, p. aurea, squarrosa*, &c. (the two last-mentioned species and their varieties are generally known in gardens under the name of Retinosporas); *Cupressus thyoides* (*Chamæcyparis sphæroidea*); the dwarf varieties of *Picea excelsa* (Norway Spruce); *Taxus baccata aurea* and *elegantissima*, also *fastigiata* (the Irish Yew); *Thuya occidentalis* (the American Arbor-Vitæ) and its varieties *aurea, erecta-viridis, globosa*, &c.; *Thuya orientalis* (Chinese Arbor-Vitæ) and its varieties *aurea compacta, elegantissima, semperaurescens*, &c. (these are generally known as Biotas). Those known as Retinosporas and Biotas are decidedly the best of the Conifers for Winter Bedding.

A large number of our hardy evergreen shrubs are also suitable for Winter Bedding, of which the following might be mentioned: Aucubas; *Berberis Aquifolium* (generally known as *Mahonia Aquifolia*) and *B. Wallichiana*; *Buxus* (Box) in variety; *Euonymus japonicus* and *radicans variegata*; Hollies, in variety; Ivies (the different forms of Tree-Ivy); Laurels (especially the Portugal); Laurustinus; Osmanthus (a dwarf Holly-like plant); Pernettyas; Phillyreas; Skimmias; &c. The variegated Euonymus and variegated Tree-Ivies are the showiest of the evergreen shrubs, and may be used with excellent effect in combination with any of the other subjects mentioned; the former is an excellent edging plant.

As a rule, it is best to keep Beds of mixed Conifers distinct from those of shrubs, but such plants as the Yew will be quite at home in either combination, and Beds devoted to the Yew and Osmanthus, with an edging of variegated Euonymus, present a very cheerful appearance during winter.

It is not necessary to confine Winter Bedding strictly to the planting of Conifers and evergreen shrubs, for many other hardy evergreen plants, such as the large-leaved Saxifrages or Megaseas, may be used with equal effect; but enough has been said to show that there is no dearth of subjects suitable for this much-neglected style of Bedding.

BEEF-STEAK FUNGUS (*Fistulina hepatica*). This liver-coloured Fungus is found growing upon living Oaks, and according to Hartig is responsible for a "deep red-brown decomposition in the wood." It is edible and very delicious.

BEEF-SUET TREE. *See* **Shepherdia argentea.**

BEERA. A synonym of **Hypolytrum** (which *see*).

BEET. The following additional varieties in their respective sections may be recommended. *Pyriform:* Cheltenham Green-top, Dell's Black-leaved, Gem, Johnson's Selected, Maincrop, Middleton Park, Pragnell's Exhibition, and Zulu. *Round or Egyptian Turnip-rooted:* Edmund's Blood Red, Egyptian Dark Red, Veitch's Eclipse, and Turnip-rooted Red Globe. *Spinach or Perpetual:* Silver or Seakale, Spinach or Green Perpetual. Both these varieties are useful in dry seasons when the Spinach runs to seed quickly, as the leaves make an excellent

Beet—*continued.*

substitute for that vegetable. *Bedding:* Black Selected, Dell's Black-leaved, Dracæna-leaved, and Zulu. The Chilian Beet is excellent for sub-tropical bedding, as the foliage is massive, with large, prominent, highly-coloured midribs. Seeds may be sown where the plants are intended to remain at the end of April.

BEETHOVENIA. A synonym of **Ceroxylon** (which *see*).

BEETLES (*Coleoptera*). Though the individuals which go to make up this vast Order cannot be said to possess the intelligence exhibited by certain *Hymenoptera*—Ants, Bees, and Wasps, for example—the gorgeous colours of many Moths and Butterflies (*Lepidoptera*), or the high organisation of the insects comprising these Orders, or even the *Diptera* (Flies), yet they are numerically the strongest of all insects, are extremely diverse as to habits, and world-wide as to their distribution. The number of species is put down at 150,000, of which 3300 belong to Britain alone. The life-history of Beetles generally is but little understood, as frequently their habits are such as to preclude close investigations being made. Much, therefore, with regard to the larval and pupal stages, yet remains to be discovered.

The majority of Beetles are capable of flight, although they are not so often recognised upon the wing as Moths and Butterflies; but there are many which are quite unable to fly. In the latter case the membranous hind-wings are either very rudimentary or altogether wanting, and usually the horny fore-wings (elytra), which fit so beautifully along the centre of the back, are "fused" together, or "soldered." Occasionally the wings are wanting, as in the soft-bodied female Glowworm, while the male is amply provided (see Fig. 159). Beetles, too, which are incapable of flight, generally run very rapidly—Ground Beetles for instance; while others both run and fly with great rapidity, as is the case with the Tiger Beetles.

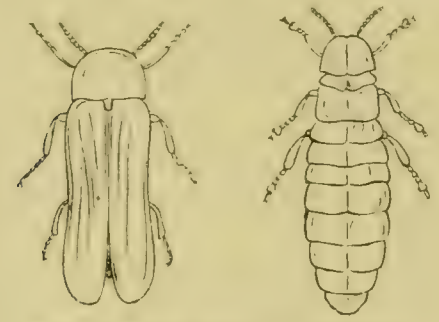

FIG. 159. MALE AND FEMALE GLOWWORMS.

The larvæ, or grubs, of Beetles are rarely seen, compared, say, with those of Butterflies and Moths. Speaking generally, they are made up of a head, three thoracic segments, either nine or ten abdominal segments, nine pairs of spiracles, and frequently a peculiar protrusion at the anal extremity of the body. Some, like those of the Ground Beetles and the Tiger Beetles, are very active, and all are wonderfully adapted to the kind of life they have to lead. Wood-feeding larvæ (which are well protected) are soft-bodied, hard-headed creatures, with exceptionally strong jaws; and so, too, are the larvæ of certain Beetles living under the soil protected—Cockchafers, Rose-chafers, and the like. Then there are others which feed exposed, like the larvæ of the well-known Ladybirds.

Beetle larvæ differ markedly as regards the length of time they remain in that condition. Wood-feeders—of which the Musk Beetle, Stag Beetle, and Bark Beetles

Beetles—*continued.*

are familiar examples—take several years. Again, the ubiquitous Wireworms are two years at least as larvæ. Occasionally two distinct forms of larvæ are evolved from the same individual; this is known as hypermetamorphosis, and it is met with in the very abundant Pea Weevil (*Bruchus pisi*). The young larvæ of this are very different-looking animals from the older grubs. The former possess three pairs of legs; but these are lost after the larvæ enter the pea-seed, and approach the full-fed condition. As the young larvæ of the Pea Beetle have to penetrate both pod and seed of their food-plant, these legs, as well as the cutting spines found upon the pronotum, aid them considerably. A still more interesting example is the young larva of the soft-bodied, sluggish indigo-blue Oil Beetle (*Meloe*). It is an insect capable of running, and may be found in Buttercups and other flowers in summer awaiting the arrival of certain bees, to which the larvæ attach themselves, and are carried to the nests. Once there, they feed first upon the eggs and afterwards upon the stored honey. While with the bees they undergo several changes: at one time they possess short legs, which, by a gradual process, are reduced to mere tubercles, and then finally disappear. There are four moults, and, except for a short time between one of them (when the jaws are rendered quite useless), the grubs feed upon the honey.

The pupal stage of Beetles is variously passed. Commonly a cocoon is elaborated from the food-plant and the soil, and in this it is assumed; or it may be passed merely in a hollowed-out place in the soil. Ladybirds, however, differ considerably in this respect; they remain suspended by the tail to the food-plants. The duration of this stage of Beetles cannot be fixed with certainty, and it may be anything from a week or ten days to a month or less. Frequently the perfect insects—Cockchafers in particular—remain beneath the soil some considerable time before finally emerging, as at first all are soft-bodied, and destitute of any distinctive colour.

To enable the gardener to understand the external anatomy of Beetles, a dissection of the Stag Beetle is given, and the various parts are briefly explained (see Fig. 160).

As a rule, the several members of the great Order *Coleoptera* are destitute of an external covering of the nature of hairs or scales, and even if these are present, the former are usually few in number, while the latter are very small, and not easily to be distinguished separately without the aid of a lens. Owing to this fact, and the further one that Beetles are fairly typical insects, and contain in their ranks members of goodly proportions, it is not a difficult matter to make out the external anatomy of an insect in general, and of this order in particular, especially if one of the larger species be selected. The work, too, is still further facilitated through the external skeleton being firm, and therefore easily manipulated.

A first glance is sufficient to show that primarily the body of the insect has three great divisions, the anterior one being the head, and the next the thorax, while the abdomen brings up the rear. Each of these, however, is either sub-divided or possesses appendages, or is modified in both directions.

First, as to the head. On the upper surface (I., A.), *a* is the labrum, or upper lip; *b*, the clypeus; *c*, the vertex, or crown; *d*, the occiput. As appendages to this surface of the head, we find the antennæ (*e*) and the mandibles, or upper jaws (*f*).

Though extremely variable in length and appearance, the antennæ nearly always consist of eleven joints, the basal one being often long and the next one short. They are employed as sense-organs, though what particular sensations are received by their means is still somewhat problematic. The mandibles in the male of the Stag Beetle are enormously developed, and modified into a pair of powerful pincers, which the insect knows well how to

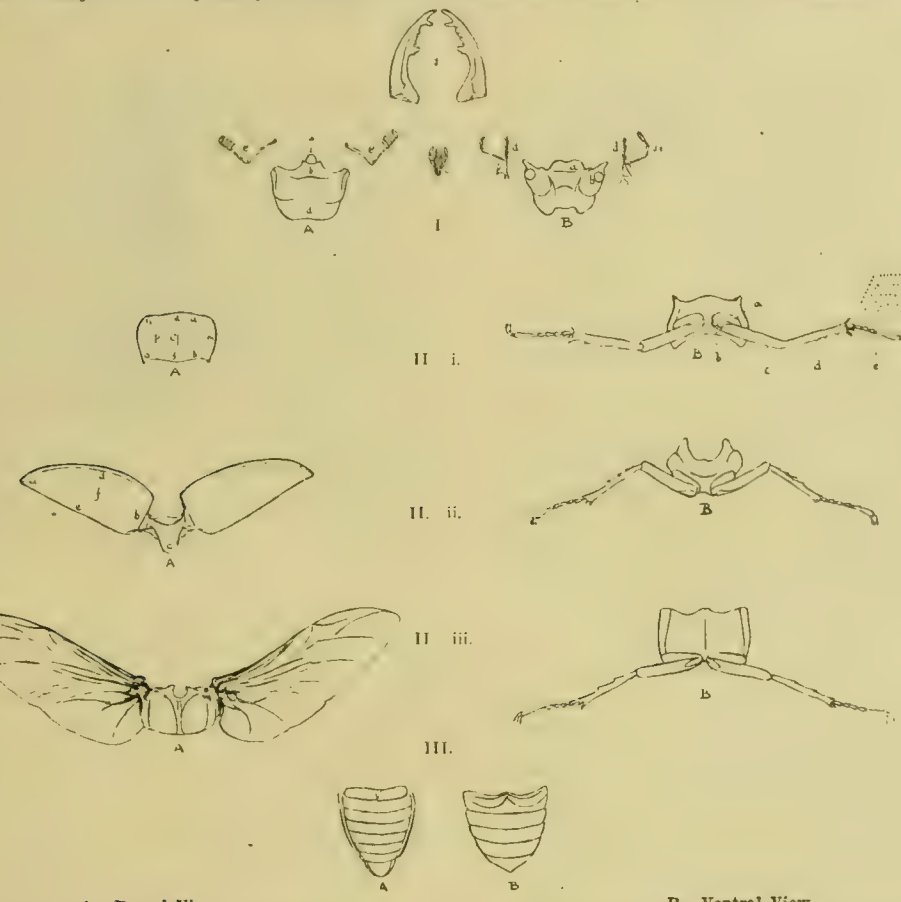
Beetles—*continued.*

use. Had *Dytiscus marginalis* been selected for dissection, the mandibles would have been found doing their proper duty as jaws—a duty which may easily be inferred also from an inspection of the head of the pretty Tiger Beetle (*Cicindela campestris*) or one of the Garden Beetles (*Carabus*).

Beetles—*continued.*

Of the lower surface (I. B.) of the head, *a* is the mentum, or chin, which, with the ligula and accompanying paraglossæ and labial palpi (*c*), forms the labium, or lower lip. *b* is the eye, and *d* are the maxillæ, or lower jaws, with their accompanying maxillary palpi (*d i*).

Passing now to the second division of the body—the



A.—Dorsal View. B.—Ventral View.

FIG. 160. DISSECTION OF EXTERNAL SKELETON OF STAG BEETLE (*Lucanus cervus*), SOMEWHAT REDUCED.

DESCRIPTION OF PLATE.

I.—**Head.**
- A. Dorsal surface.
  - *a.* Labrum.
  - *b.* Clypeus.
  - *c.* Vertex, or crown.
  - *d.* Occiput.
- B. Ventral surface.
  - *a.* Mentum.
  - *b.* Eye.

  The head bears:
  - *c.* Ligula, with paraglossæ and labial palpi.
  - *d.* Maxillæ, or lower jaws.
  - *d. i.* Maxillary palpi.
  - *e.* Antennæ.
  - *f.* Mandibles, or upper jaws.

II.—**Thorax.**—i. Prothorax. ii. Mesothorax. iii. Metathorax.
- i. A. **Pronotum.**
  - *a.* Anterior margin.
  - *b.* Posterior margin.
  - *c.* Medial line.
  - *d.* Apex.
  - *f.* Base.
  - *m.* Lateral margin.
  - *n.* Anterior angles.
  - *o.* Posterior angles.
  - *p.* Disc.
- i. B. **Prosternum,** bearing the fore or anterior pair of legs, having the following divisions:
  - *a.* Coxa.
  - *b.* Trochanter.
  - *c.* Femur.
  - *d.* Tibia.
  - *e.* Tarsus, with five joints, the last terminated by a pair of ungues, or hooks.
- ii. A. **Mesonotum,** bearing the two elytra, on which are:
  - *a.* Apex.
  - *b.* Base.
  - *c.* Scutellum.
  - *d.* Lateral margin.
  - *e.* Suture.
  - *f.* Disc.
- ii. B. **Mesosternum,** bearing the mid-pair of legs.
- iii. A. **Metanotum,** bearing the two wings.
- iii. B. **Metasternum,** bearing the two hind-legs.

III.—**Abdomen.**
- A. Dorsal surface.
- B. Ventral surface.

Beetles—*continued.*

thorax (II. A. and II. B.)—it is found divided into three rings, called respectively, i. the prothorax, ii. the mesothorax, and iii. the metathorax. In each case the dorsal surface is distinguished as the -notum and the ventral as the -sternum.

Of the pronotum (II. i. A.) (which is without appendages), *a* is the anterior, *b* the posterior, and *m* the lateral margin. *c* is the medial line, *d* is the apex, *f* the base, *n* the anterior, and *o* the posterior angles, while *p* is the disc.

Beneath the pronotum is found the prosternum (II. i. B.), carrying the fore or anterior pair of legs, each of which, like the other four, have the following divisions: *a*, the coxa; *b*, a very small joint, the trochanter; *c*, the femur; *d*, the tibia; *e*, the tarsus, with five joints (in this insect), the last terminating in a pair of ungues, or hooks, the use of which is very apparent if a Stag Beetle be held in the hand.

In II. ii. A. is seen the mesonotum; this carries the two elytra, hardened shell-like appendages, which are modified representatives of the fore-wings of other insects. On them are the apex, *a*; base, *b*; lateral margin, *d*; and disc, *f*. When the elytra are closed, the line along which they meet is called the suture, *e*; and a little triangular shield, the scutellum, *c*, is seen on the middle line at the anterior extremity of the suture.

The mesosternum (II. ii. B.) bears the mid pair of legs, whose divisions are the same as those of the fore pair.

II. iii. A. represents the metanotum carrying the membranous wings which, when the insect is at rest, are folded away very carefully beneath the elytra, so as to be out of danger. Beneath the metanotum is the metasternum, II. iii. B., bearing the hind pair of legs, whose parts are again the same as those of the fore-legs.

III. A. shows the dorsal surface of the abdomen, and III. B. the ventral, both being divided into a number of segments. The greater part of the dorsal surface in most Beetles is shielded by the elytra, and is therefore softer than the ventral surface, which has no protection.

Many attempts have been made, with more or less success, to classify the Beetles. Still, the fact remains that, even in the present state of knowledge, there are a vast number of forms which cannot well be brought together by any hard-and-fast system of classification, and these have been styled *Polymorpha*. It would serve no good purpose to minutely classify this vast Order. All that the gardener needs to know are the leading characteristics of the families containing either friends or foes, or both. To separate the one from the other is not by any means an easy matter, but unless he is able to discriminate somewhat, he may be destroying, unwittingly, some of his greatest friends.

Below are the leading characteristics of the families of Beetles most interesting to gardeners and farmers, arranged alphabetically.

Bruchidæ are small Beetles, several species of which are destructive to the seeds of leguminous plants. The head is produced in front, but not prolonged into a beak, and is partly hidden beneath the pronotum. The feet appear as if but four-jointed, but a fifth really exists. To this family belong the well-known Pea Weevil (*Bruchus pisi*), as well as the Bean Pests (*B. rufimanus* and *B. fabæ*), referred to under **Bruchus.**

Carabidæ, or **Ground Beetles.** These are closely related to the *Cicindelidæ*, chiefly differing from them in the face being narrower, and in the absence of a hinged hook to the first maxilla, and in the eyes being less prominent. By far the majority of them are useful in gardens, and as some few are amongst the commonest of Beetles their good qualities should not be overlooked. Fig. 161 represents *Carabus nemoralis*, which may be found

Beetles—*continued.*

FIG. 161. GROUND BEETLE *(Carabus nemoralis).* (Twice natural size.)

almost everywhere in town or in country. As the common name suggests they are largely terrestrial in their habits. Frequently they are incapable of flight, the elytra being soldered. Although not so predaceous as the Tiger Beetles, they will attack both living and dead insects; while the larvæ are also similarly useful and very active. In form the larvæ are elongate, possess very powerful calliper-like jaws, and the hind part of the body bears two peculiar processes and a mid-tube. In the genera *Harpalus*, *Pterostichus*, *Zabrus*, *Amara* ("Sunshiners"), and *Calathus*, are to be found individuals which occasionally forsake their usual carnivorous dietary for a vegetarian one. *Harpalus ruficornis*, *Pterostichus madidus* (Fig. 162), and *Calathus cisteloides*, all prey upon Strawberries; while *Zabrus gibbus* and several *Amara* are at least in part plant feeders, the former being destructive to corn.

FIG. 162. PTEROSTICHUS MADIDUS.

Cerambycidæ, or **Longhorn Beetles,** are very closely allied to the *Chrysomelidæ*. The species are, as a rule, elegant insects, of oblong form, and with usually long serrate or pectinate antennæ. The tarsi are five-jointed, though the fourth segment is with difficulty differentiated from the fifth. One of the most elegant representatives found in gardens is the sweet-smelling Musk Beetle (*Aromia moschata*) (Fig. 79), whose larvæ do much damage to Willows. The Longhorns generally are wood rather than garden-inhabiting Beetles. The grubs are soft, white, and fleshy, usually with short legs, small head, and powerful jaws. Some of these Beetles are capable of making a stridulating noise, the Musk Beetle among the number.

Chrysomelidæ, or **Leaf Beetles.** These are usually bright or metallic as to colour, and oval or convex as to form, but great variability in this latter respect is shown in

Beetles—*continued.*

this very large family. To it belong several of the most destructive insects found in gardens: the Turnip Flea Beetle (Fig. 133, Vol. IV.), the Colorado Beetle (Fig. 261, Vol. III.), the Asparagus Beetle, the Mustard Beetle, and the lovely, but scarce, Lily Beetle. The larvæ are fleshy, and, like the Beetles, are leaf-feeders.

Cicindelidæ, or **Tiger Beetles.** These are sand-loving insects, flying and running with great rapidity; but the actual distance covered at each flight is not great. They are entirely carnivorous, and alike in the larval and the perfect insect form render good service to man. They capture their prey alive, and feed upon the juicy parts only. The larvæ are remarkable by reason of the fact that they lurk in their sandy burrows, supporting themselves in an upright position by means of a pair of strong hooks found upon the fifth segment of the body. The jaws are extended ready to snap any insect which ventures within striking distance, and which is promptly hurried to the bottom of the tunnel. The perfect insects have a large head, with the clypeus, or face, extending laterally in front of the antennæ. The eyes are prominent. The blade of the first maxilla has at the tip a hook-like process. The legs are long, and the tarsi (feet) five-jointed. Fig. 163 represents the common, but beautiful, *Cicindela campestris*. The Tiger Beetles, so far as this country is concerned, are sunshine-lovers, and they are the most voracious of all our native *Coleoptera*, and most useful to gardeners.

Coccinellidæ, or **Ladybirds.** These Beetles are too well known outwardly to need any description, and they are amongst the gardener's best friends, being useful in both the larval and the perfect form. They subsist largely on Aphides and Scale insects. The tarsi, at a casual glance, appear three-jointed, but closer investigation will show that the third joint is made up of two. The larvæ are very active, and before pupating suspend themselves by the hinder extremity.

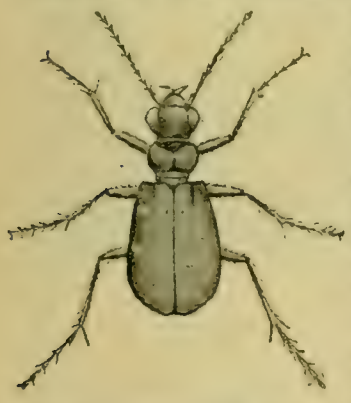


FIG. 163. COMMON TIGER BEETLE *(Cicindela campestris).* (Much magnified.)

Curculionidæ, or **Weevils,** are chiefly distinguished by a distinct but variable-sized beak (rostrum), the absence of a labrum, small, short palpi, and elbowed antennæ. Usually both Beetles and grubs are destructive, and all parts of plants, from flower-buds to roots, are laid under contribution. An interesting species, found sometimes in gardens where there are Birches, is the leaf-rolling *Rhynchites betulæ*. The genus *Otiorhynchus* is a peculiarly destructive one, the Black Vine Weevil, *O. sulcatus* (Fig. 164), being practically omnivorous. The larvæ are mostly legless, fleshy grubs, much wrinkled and curved.

Elateridæ, or **Click Beetles,** are of elongate form (see Fig. 34, page 29), with five-jointed feet, thread-like, saw-like or, less often, comb-like antennæ, and a pro-sternal process which, fitting into the meso-sternal cavity, enables the insects to spring into the air when placed upon their backs, at the same time making a "clicking" noise. The larvæ are narrow and elongate, with hard skins and short legs, and constitute the much-dreaded Wireworms of the gardener and agriculturist; they live as grubs from two to four years.

Beetles—*continued.*

Histeridæ are small shiny black or brown Beetles, ovate as to form, and with short, bent antennæ, ending in a very distinct and compact club. The elytra are straight behind, and leave two segments of the body exposed. The feet are five-jointed. The Beetles are predaceous in both the larval and the perfect state, and destroy numbers of noxious flies, &c. They are found largely in animal manures. The larvæ have neither ocelli nor labrum; the mandibles are powerful.

FIG. 164. BLACK VINE WEEVIL *(Otiorhynchus sulcatus).*

Lucanidæ, or **Stag Beetles.** In this family is to be found the largest of British Beetles, *Lucanus cervus*, whose formidable mandibles in the case of the male (Fig. 473, Vol. II.), frequently toothed, are very distinct. The antennæ end in a comb-like club, particularly pronounced in the male. It is doubtful whether these insects attack healthy trees. The larvæ live in oak and other trees for several years; they are white, fleshy, semi-circular grubs, with a horny head.

Malacodermidæ. This family contains several species of great use to the gardener, as the larvæ are predaceous carnivorous insects, feeding chiefly upon snails. The best known is the light-bearing Glowworm *(Lampyris noctiluca)*, whose wingless female and winged male have already been noted above. The feet are five-jointed. These Beetles are usually of elongate form (like the familiar Soldier Beetles, so numerous in gardens). The grubs of some, like those of the Glowworm, differ but little from the larviform females in the perfect insect stage.

Scarabæidæ, or **Chafers.** This is a very variable family. Some individuals, like the dung-buryers, are useful to gardeners; while others (Cockchafer, June Bug, and Rosechafer) are very destructive. The Beetles of this family have much in common with the *Lucanidæ*, though the plates terminating the antennæ are more compact. The grubs also are like those of the Stag Beetles, but smaller.

Scolytidæ resemble somewhat the members of the *Curculionidæ*, but the beak is very short and broad. The antennæ are short and compactly clubbed. The species are mostly wood feeders, and do damage to both fruit and park trees. They appear in vast numbers, and increase very rapidly. A tree attacked by these Beetles, if carefully examined, will be found tunnelled in all directions, the various batches of legless larvæ starting branch galleries from the vicinity of those made by the females when egg-laying.

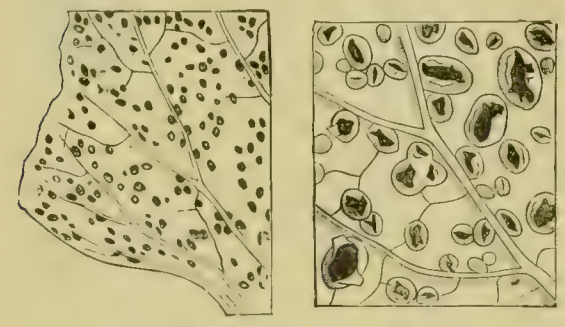
Silphidæ, or **Carrion Beetles,** include many well-known species, like the Burying Beetles (*Necrophorus*), which are useful, and at least one species which to gardeners is undesirable—the Beet Carrion Beetle (*Silpha opaca*), so destructive to Beet, &c. They vary in form and size, the familiar Burying Beetles being amongst the largest. The members of this family have usually (but not always) five-jointed feet and straight, clubbed antennæ. The larvæ are active and campodeiform; their food chiefly consists of decomposing animal and vegetable matter.

Staphylinidæ, or **Rove Beetles.** A well-marked and very numerous family, formerly comprehended under the name of *Brachelytra*, on account of the short elytra. They vary considerably in size. One of the most familiar is the Devil's Coach Horse Beetle (Fig. 225, Vol. I), or Cock-tail, a very intrepid insect, and one of the gardener's best friends. Contrary to the general opinion entertained,

Beetles—*continued.*

this Beetle can fly well. In form *Staphylinidæ* are elongate. Those commonly met with feed upon insects, molluscs, and worms. The feet are five-jointed. The larvæ are active, and in general remind one of those of the *Carabidæ*.

BEET RUST (*Uromyces betæ*). In England, America, and many parts of Europe, this fungus does an amount of damage to Garden Beets as well as to Mangel Wurzels in fields, by causing the growth to be stunted and the roots to be deformed and generally of poor quality. The Sea Beet (*Beta maritima*) is also liable to be attacked. The reddish-yellow Cluster Cup, or first stage of the fungus, is found in spring; this is



Natural size. Magnified (×10).

By permission of the Board of Agriculture.

FIG. 165. BEET RUST, Uredospore stage.

succeeded by the uredospore stage (Fig. 165), in which the spores are of a light brown, and edged with points when seen under a microscope; finally, these give place to the teleutospores, which carry the fungus on to the next season.

Preventive measures consist in spraying the plants at intervals as soon as the first stage is noticed, so as to render the foliage in such a condition that the uredospores, when they burst through the skin, will not germinate. Great care must also be taken to burn all trimmings at the time of lifting the roots in autumn, otherwise if the same quarters are used for Beet or Mangels the trouble will be intensified. Obviously, too, the eradication of any Wild Beet in the neighbourhood of the plantation is desirable.

BEFARIA. SYN. *Acunna.* This genus includes about twelve or fifteen species, natives of Mexico, Florida, Cuba, and South and Central America.

BEGONIA. Including *Eupetalum.* Of this vast genus about 350 species are known; they are mostly natives of tropical America and tropical and sub-tropical Asia and Africa, and are rarely found in the Pacific Islands.

Only a comparatively few years ago it was considered an impossibility to cross the Shrubby Begonia with the Tuberous-rooted species, but this has been successfully accomplished by Messrs. J. Veitch and Sons, Chelsea, who have produced from the union a strain which continue to blossom abundantly all through the winter months. They originated by crossing the Tuberous Begonia with the well-known winter *B. socotrana*; several distinct and handsome varieties are now in commerce, and will be extensively grown in the future. Perhaps the most useful and beautiful of all winter-flowering Begonias is the charming Gloire de Lorraine, raised by MM. Lemoine and Son, of Nancy, by crossing *B. Dregei* and *B. socotrana*; the foliage is a beautiful green, of the same shape as *B. socotrana*, but very much smaller; the stems are slender, terminating

Begonia—*continued.*

in a cymose inflorescence of lovely clear pink flowers. A beautiful white sport has been produced, resembling Gloire de Lorraine in all respects except in the colour of the flower. So far no hybridiser has been able to cross Gloire de Lorraine with any species or variety, nor have any fertile seeds been produced; therefore, the only means of propagating is by stem- or leaf-cuttings, both of which root readily if placed in a little bottom-heat in a temperature of 70deg. *Begonia incomparabilis* originated by crossing *B. polypetala* and *B. Frœbeli*, and produces bright scarlet flowers above the large foliage of the dwarf plant, commencing to blossom in summer, and continuing until late in the year. The above are the best of the new forms of the Begonia for winter-flowering, and are sure to become popular.

The freedom with which the Begonia is employed for bedding in the public parks and gardens of our large towns at once stamps it as a most useful and reliable plant for smoky districts. It appears to great advantage when compared with many other subjects, especially after heavy storms of rain, when Pelargoniums and kindred plants are miserable-looking objects, all the flowers being knocked to pieces, and anything but attractive. The Begonia, however, appears as fresh and beautiful as ever, and looks as if it had enjoyed the heavy rain. To produce the best effect the plants should have a start into growth in gentle heat, commencing about the middle of April, using a rich compost for the tubers, and afterwards keeping them close to the glass to induce a short-jointed, sturdy growth. By the middle of May the plants may be placed in a cold frame, not giving much ventilation for a few days; afterwards they should be gradually exposed to more air, removing the lights entirely on warm days and nights. By the first week in June they will be hardened sufficiently to plant out in beds that have been well enriched previously with good farmyard manure. Seedlings such as Fig. 166 are frequently employed in bedding with good effect.

Where many have failed with the Begonia is by planting out in poor soil, or under the shade of trees, both of which are disliked by the Begonia. If a mulch of well-rotted manure can be applied to the soil immediately after planting, not only is moisture conserved, but the roots are fed to such an extent that floriferous growth is made all through the season, until the plants are cut down by frost. Under the conditions advocated no plant will surpass the Begonia for bedding purposes, and few equal it for town or villa gardens, where the atmosphere is more or less charged with obnoxious matter. Another advantage is that the Begonia may be taken up and stored away in boxes in a fairly warm, dry place, and no further attention is necessary until started into growth again in the spring; whereas the Pelargoniums and other soft-wooded plants must be potted and given attention in watering, &c., all the winter, amounting to a considerable cost altogether.

Begonia Haageana is a lovely plant for an intermediate house, as it is free in growth and nearly always in blossom. The large flesh-coloured flowers are borne in great clusters. *B. semperflorens* is a particularly valuable mid-winter flowering plant, as its white flowers are borne freely. It is also useful for summer-bedding, as the foliage is heavily stained with crimson and deep purple-bronze in August, at which time it is one of the most conspicuous features in the flower-garden. The variety named *gigantea rosea* is of strong growth, and bears an abundance of rosy-red flowers. *B. fuchsioides* is a good pillar-plant, and bears drooping panicles of bright scarlet flowers freely.

To the species and varieties described on pp. 170-9, Vol. I., the following should be added.

B. acerifolia. S. This name has also been applied by Messrs. Veitch and Sons to a garden hybrid between *B. Burkei* and *B. decora.*

Begonia—*continued.*

B. albo-picta (white-painted). S. *l.* shortly stalked, small, elliptic-lanceolate, glossy-green, freely spotted with bright silvery-white. Brazil.

B. Ameliæ (Amelia's).* *fl.* bright rose-coloured, disposed in terminal, trichotomously-branched cymes. *l.* obliquely cordate-ovate, crenulate, shining green. 1885. Habit robust, compact, and branching. A greenhouse, garden hybrid between *B. Bruantii* and *B. Lynchiana.* (R. H. 1885, p. 512, f. 89-90.)

B. ascotiensis (Ascot). *fl.* bright dark red, disposed from six to twelve in a cyme; peduncle 3½in. to 4in. long. Summer. *l.* ovate, thick, shortly petiolate, smooth, very finely toothed. *h.* 2ft. to 3ft. Origin unknown.

B. Baumanni (Baumann's).* T. *fl.* carmine-rose, 3in. to 4in. in diameter, agreeably scented; peduncles purplish, erect, leafless, 1ft. to 1½ft. high, about five-flowered. *l.* few, reniform, dark green above, purplish beneath. Rootstock producing short, fleshy stems. 1890. An elegant, greenhouse species, with the habit of *B. socotrana.* (B. M. 7540.)

B. Beddomei (Beddome's).* T. *fl.* pale rose-coloured, cymose, the males 1½in. in diameter, the females smaller and darker; scape shorter than the petioles, brown-scaly. December. *l.* radical, erect; blade horizontal, 4in. to 6in. in diameter, membranous and pellucid, broadly and obliquely ovate-cordate or orbicular-cordate, obscurely lobed and denticulate, ciliolate, pale green with white spots above, dull red-purple beneath; petioles hairy, 4in. to 6in. long. Assam, 1883. (B. M. 6767.)

FIG. 166. SEEDLING TUBEROUS-ROOTED BEGONIA.

B. Bertini (Bertin's).* T. *fl.* reddish-scarlet, very large, less pendent, very numerous. Otherwise the plant resembles *B. Worthiana.* 1894. (R. H. 1894, p. 247, f. 93-94.)

B. bicolor (two-coloured). *fl.* bright rose, disposed in a terminal raceme; peduncles one- to three-flowered. *l.* broad, obliquely reniform, green, spotted with white, the upper ones having bulbils in their axils. Mexico, 1891. A tall, erect-growing, greenhouse species.

B. Bismarcki (Bismarck's). *fl.* light satiny-rose, 1½in. across; panicles large, drooping, many-flowered. November and December. *l.* large, lobed, very acuminate, oblique, 6in. long. 1888. Garden variety.

B. boliviensis sulphurea (sulphur-coloured). *fl.* sulphur-yellow, spreading, small but very pretty. *l.* long and velvety. 1895. A pretty variety for pot-culture.

B. Carrieri (Carrière's).* This is said to be a hybrid between *B. semperflorens* and *B. Schmidtiana.* The flowers are nearly as large as those of *B. semperflorens rosea*, and are produced much more plentifully. *l.* roundish-ovate, of a bright, cheerful green. Small plants appear to flower with great freedom. 1884.

B. castaneæfolia (Castanea-leaved). A synonym of *B. fruticosa.*

B. cinnabarina albo-vittata (white-striped). A garden variety having the petals striped with white. 1892. (I. H. xxxix. 165.)

B. Clementinæ (Princess Clementine's). *l.* large, deflexed, roundish-ovate, cordate at the base, the margin lobed; upper surface bronzy-green, irregularly banded greenish-white; under-surface rose-coloured, with ribs of a darker hue. 1883. A hybrid, said to be raised between *B. diadema* and *B. Rex.* (G. C. ser. iii., vol. iii., p. 265; I. H. xxxv., t. 39.)

B. compta (adorned). *l.* of a satiny green, a silvery tinge running along the course of the midrib, obliquely ovate, angular. Brazil, 1886. A pretty, greenhouse plant.

B. coronata (crowned). A garden hybrid of which *B. caroliniæfolia* is one of the parents.

B. Credneri (Credner's). A garden hybrid between *B. Scharffi* and *B. incarnata metallica.* 1890. (R. G. 1890, p. 562, f. 80.) SYN. *B. Scharffi metallica.*

B. cyclophylla (round-leaved). T. *fl.* rose-coloured and rose-scented, disposed in a trichotomous cyme, the males 1in. to 1½in. in diameter; scape 6in. high, slender, glabrous. April. *l.* solitary, 6in. broad, orbicular-cordate, with overlapping basal lobes, obtuse or sub-acute, palmately seven- to nine-nerved, obscurely denticulate; petiole shorter than the blade. South China, 1885. (B. M. 6926.)

B. Davisii superba (superb). A double-flowered variety. 1881.

B. decora (decorative). S. *l.* dark green, profusely dotted with silvery-grey, something in the way of those of *B. maculata*, but the spots more minute, obliquely lanceolate. Brazil, 1886. Stove.

B. diadema (diadem).* *l.* deeply digitate-lobed; lobes irregular, glossy, quite glabrous, light green, irregularly marked with white blotches; under-surface with a red zone near the stalk. A handsome foliage plant. Borneo, 1883. (I. H. xxix. 446.)

B. Duchartrei (Duchartre's).* *fl.* white, 2in. in diameter, the males with four petals, the females with five. Winter. *l.* 6in. to 12in. long, ovate-lanceolate, acute at apex, dark green, with a dark reddish-violet midrib; petioles 2in. long. *h.* 3ft. 1892. A vigorous hybrid between *B. echinosepala* and *B. Scharffi.* (Gn. 1892, vi., p. 115; R. H. 1892, p. 29, f. 7.)

B. egregia (notable).* *fl.* white, ½in. across, many in a gracefully drooping, corymbose cyme 3in. to 4in. in diameter; peduncle 2½in. to 3in. long. Winter. *l.* peltate, 8in. to 11in. long, 2½in. to 4in. broad, obliquely oblong, acuminate, obtusely rounded at the unequal base, hairy; petioles 2½in. to 3in. long. Stem woody below. *h.* 3ft. to 4ft. Brazil, 1887.

B. erecta cristata (crested). A very curious form, having the tips of the petals lamellate and crested, imparting a cruciform appearance to the inside of the flowers. (R. H. 1896, p. 61, f. 17.)

B. Faureana (Felix Faure's). *l.* ample, deeply cut into five to seven lobes, rather large, acute or sub-obtuse, of a tender green, zoned with white. Stem strong, arborescent, scaly. Tropics. SYN. *B. platanifolia*, of gardens (I. H. 1889, p. 152, t. 34).

B. F. metallica (metallic). A variety having metallic reflections on the leaves. 1895. (I. H. 1895, t. 43.)

B. fruticosa (shrubby). *fl.* pink, small, sub-umbellate; cymes often shorter than the leaves. February. *l.* ovate-oblong, 2in. to 3in. long, seven to nine lines broad, penninerved, shortly petiolate, obtuse or sub-acute at base, repandly serrate-toothed, glabrous, and, as well as the stipules and bracts, persistent. *h.* 3ft. Brazil, 1838. SYN. *B. castaneæfolia.*

B. f. alba (white). A large and robust variety, with white flowers.

B. fulgens (brilliant). T. *fl.* rich red, fragrant, disposed in numerous racemes. *l.* green, roundish-oblique. Bolivia, 1893. Closely related to *B. Davisii.*

B. glaucophylla (glaucous-leaved).* *fl.* pink, small; male sepals two, broadly ovate, obtuse, petals two, much smaller, incurved; female sepals four, broadly ovate, concave; panicle ample, many-flowered, nodding or pendulous. *l.* petiolate, oblong-lanceolate, acuminate, the margins undulated. Stem elongated, pendulous, the branches white-spotted. Brazil. A capital basket plant. (B. M. 7219.)

B. globosa (globose). A garden hybrid. 1888. (R. G. 1888, p. 645, f. 143.)

B. gracilis racemiflora (racemose-flowered). A useful, decorative variety, of bushy habit, having darker flowers than the type, and red stems. 1886.

B. Haageana (Haage's). A synonym of *B. Scharffi.*

B. Hemsleyana (W. B. Hemsley's).* T. *fl.* pale pink, darker towards the tips, few in a dichotomous cyme; males 1½in. across; females rather larger; capsule three-winged. April onwards. *l.* erect, orbicular, 3in. to 5in. across, palmati-partite or almost

Begonia—*continued.*

pedate; segments seven to nine, radiating, lanceolate, serrated. Stem 1ft. to 1½ft. high, sparingly branched, hairy. Yunnan, China, 1898. (B. M. 7685.)

B. heracleicotyle (hybrid). A hybrid between *B. heracleifolia* and *B. hydrocotylifolia.*

B. Hoegeana (Hoege's). *fl.* white, disposed in lax, axillary cymes, only half as large as those of *B. nitida* (which this plant somewhat resembles). *l.* broadly ovate, rounded at base, scarcely oblique. Mexico, 1886. A very glabrous, greenhouse climber.

B. hybrida coccinea (red). *fl.* bright scarlet, freely produced. Winter. A desirable hybrid, of dwarf, compact habit.

B. Jaurèzi (Jaurez'). A garden variety with semi-double flowers. 1890.

B. Johnstoni (Johnston's). *fl.* pale rose-coloured; males 1½in. to 2in. in diameter, with four broadly oblong sepals and numerous stamens; females smaller, with five sepals; cymes four- to six-flowered; peduncles long. April. *l.* 4in. to 6in. long, obliquely ovate, acute, coarsely crenate, deeply two-lobed at the base, hairy; petioles 4in. to 6in. long. Stem succulent, 1ft. to

Begonia—*continued.*

hairs at the base. *l.* large, obliquely cordate-ovate, dark, shining green, with purple reflections. 1884. A garden hybrid between *B. echinosepala* and *B. incarnata metallica*, of tall and vigorous habit. (R. H. 1884, p. 200, f. 43.)

B. marginata illustrata (margined, illustrated). *l.* slightly bullate, borne on tall, densely hairy stalks, the pea-green ground being reticulated with depressed veins of green and chocolate colour. 1897. A garden seedling.

B. Meysseliana (Meyssel's). *l.* pale green, ornamented with silvery spots. Sumatra, 1884. A stove or greenhouse, foliage plant, suitable for outdoor decoration in summer.

B. octopetala Lemoinei (Lemoine's). A garden hybrid, raised in 1889. (R. H. 1889, p. 32, f. 7.)

B. olbia (rich). *fl.* white, in small cymes, freely produced from the axils of the leaves. *l.* oblique, five-nerved, irregularly toothed, slightly bullate, the upper surface of a very dark bronzy-green, covered with small, reddish hairs, and studded with small, neat, round, white spots, the under-surface of a deep red; petioles erect. Stems short, fleshy. Brazil, 1883. (F. & P. 1884 603.)

FIG. 167. BEGONIA DUCHESS OF MARLBOROUGH.

1½ft. high, and, as well as the branches, petioles, peduncles, and pedicels, marked with scarlet striæ. Tropical Africa, 1884. (B. M. 6899.)

B. Lansbergeæ (Mme. van Lansberge's). *l.* 6½in. long, 3½in. broad, very thick, obliquely cordate-ovate, long-acuminate, deeply sinuated, entire, with rounded lobes, on long petioles. Brazil, 1893. Plant villous. (I. H. 1893, t. 174; R. H. 1893, p. 202.)

B. Lemahoutii (Le Maout's). *fl.* white, tinted with rose on the outside, produced in cymes; peduncles rising above the leaves. *l.* oblique, acuminate, dark green above, washed with purple beneath, wavy, toothed and ciliated on the margins. 1889. A compact, greenhouse species, of unknown origin.

B. Lesoudsii (Lesoud's). A garden hybrid,

B. Lubbersii (Lubbers').* *fl.* white, tinged green, large, in axillary, nodding cymes of about six. *l.* alternate, distichous, smooth, entire, peltately attached to fleshy petioles; stipules large, ovate, persistent, bright red. Stems cylindrical, green, deflexed at the tips. Brazil, 1884. A handsome, sub-shrubby species. (B. H. 1883, 13.)

B. manicata aureo-maculata (golden-spotted). *l.* round, mottled with white.

B. Margaritæ (Margaret's). *fl.* pale rosy, large, in corymbose cymes; sepals of the males orbicular, having a large tuft of rosy

B. patula (somewhat spreading). S. *fl.* pink, many in a cyme. *l.* obliquely-cordate, angled or doubly toothed on the margin, dark green and sparsely hairy above, reddish beneath. *h.* 3ft. Brazil, 1889.

B. pictaviense (Poictiers). A garden hybrid between *B. Scharffi* and *B. incarnata metallica.* 1891.

B. platanifolia. There are several varieties of this species, including *decora*, *illustris*, and *pulvinata*, of which the first-named is the most desirable owing to its predominating silvery marking. 1894.

B. platanifolia (of gardens). A synonym of *B. Faureana.*

B. rubella (reddish). *l.* numerous, obliquely ovate, lobed, toothed, ciliated, bronzy-green, the veins marked out with pale green, spotted all over with purplish-brown, the under-surface red. Stems stout, decumbent. India, 1883.

B. Scharffi (Scharff's).* *fl.* white, in large, long-stalked corymbs; males 2in. to 2½in. across, having two large, elliptic sepals echinate with red bristles outside, and two narrow, spathulate petals; females smaller, with obovate segments. *l.* 4in. to 10in. long, 2in. to 5in. broad, obliquely cordate-ovate, acuminate, purplish beneath. *h.* 1½ft. to 2ft. South Brazil, 1889. A handsome, free-flowering, stove species, hispid with red hairs. (B. M. 7023.) SYN. *B. Haageana* (of gardens).

B. S. metallica (metallic). A synonym of *B. Credneri.*

FIG. 168. BEGONIA DIAMOND JUBILEE.

B. semperflorens rosea (rosy). *fl.* bright rose-coloured, the petals white at base. 1883. A pretty, free-flowering, garden variety. (R. H. 1881, p. 330.) *rosco-multiflora* is a many-flowered form. 1892.

B. s. Sturzii (Sturz'). *fl.* rose-pink, disposed in cymose panicles. *l.* whitish-spotted. 1886. A fine, floriferous variety. (R. G. 1220.)

B. sinensis (Chinese). T. *fl.* bright rose-red, monœcious, in axillary and terminal cymes; males ¾in. across; females rather larger. October. *l.* 3in. to 5in. long, more or less unequal-sided, ovate-cordate, acuminate, obscurely lobulate, serrated and serrulated, pale and often rosy beneath, hairy. Stem 1½ft. to 2ft. high. China, 1838. Greenhouse. (B. M. 7673.)

B. socotrana. Seedling hybrid forms have been obtained by crossing the summer-flowering, tuberous, garden varieties with *B. socotrana.* The following are of great horticultural value, as the blossoms are freely produced during the winter months, and the richly-coloured sprays of flowers are valuable for placing in vases: ADONIS, flowers rosy-carmine, medium-sized, leaves large and handsome, habit robust and erect; AUTUMN ROSE, flowers rose-pink, pretty, intermediate between those of *B. incarnata* and *B. socotrana* (the pollen parent); JOHN HEAL, flowers clear rose, lasting for two or three weeks, leaves much smaller than those of ADONIS, habit graceful; MRS. HEAL, the finest variety yet raised, flowers rose-carmine, 3in. in diameter, leaves like those of JOHN HEAL, habit erect; WINTER GEM, flowers more crimson than carmine, freely produced, leaves rhomboid, more like *B. socotrana* than the other hybrids. The first three can be freely propagated by cuttings; but the last can only be increased by the small tubers at the base of the stem.

B. subpeltata (somewhat peltate). *fl.* pale rose, with four petals, disposed in cymes. *l.* large, obliquely cordate, acute, 4in. to 4½in. long, bright carmine when young, becoming bronzy. *h.* 12in. to 16in. Garden hybrid.

B. umbraculifera (umbrella-bearing). *fl.* white, chiefly male, but a few female and bisexual; males 1in. across, with two sepals and about twenty stamens; females ¼in. across, with five sepals; cymes large, dichotomously branched. March. *l.* alternate, fleshy, 4in. to 6in. across, the lower ones reniform, the upper ones peltate. Stems 4ft. high, simple. Brazil, 1893. Remarkable for bearing hermaphrodite flowers, *B. frigida* being the only other species that does so. (B. M. 7457.)

B. venosa (veined). *fl.* white, small, disposed in slender, axillary cymes on red peduncles. *l.* large, sub-peltate, fleshy, freely sprinkled on the upper surface with silvery-grey scales; stipules very large (2in. long), transparent, membranous, strongly veined. Brazil, 1899. (B. M. 7657.)

B. Viaudi (Viaud's). *fl.* white, with a pink centre, very numerous. 1897. A garden hybrid between *B. Duchartrei* and *B. pictaviense.* (R. H. 1897, p. 561, f. 167.)

B. Worthiana (Worth's). A pretty variety obtained from seeds of *B. boliviensis*, from which it differs in having more abundant and less pendent flowers, and larger but shorter leaves. 1870.

Varieties of Tuberous Begonias. These have increased in popularity during the last few years, and the colour-range has also been greatly improved. Subjoined are some varieties that may be recommended.

Single-flowered.—*Crimson and Scarlet Shaded:* EARL OF CRAVEN, bright scarlet, very large and full, free and vigorous; LADY TYLER, intense scarlet, very large, of fine form, and free; LORD PEEL, deep crimson, of fine form and substance; MARS, bright scarlet, free and vigorous; MRS. H. G. MURRAY, rich scarlet, large, floriferous, and one of the best; SIR SYDNEY, deep crimson, very dwarf, and excellent in all points; SIR TREVOR LAWRENCE, beautiful crimson-scarlet, large, dwarf bushy habit.

Rose-coloured CHATTERTON, dark rose, free and strong, one of the largest; COLOSSUS, deep orange, shaded rose, very large, one of the finest; J. RICHMOND, magenta-rose, fine form, dwarf sturdy habit; MRS. NEWMAN, soft rose, very large, and fine for exhibition; ODORATA ROSEA PLENA, bright rose, remarkably free and sweet-scented.

White-flowered: BEAUTY, pure white of fine form, great size, and very free;

FIG. 169. BEGONIA MRS. PEREIRA.

Begonia—*continued.*

LAING'S FRINGED WHITE, a robust, floriferous variety, with the margin of the flowers beautifully fringed; MISS MALCOLMSON, very large, fine bushy habit; NELLY PRITCHARD, pure white, fine circular flower, of good habit, and wonderfully free; SAMUEL POPE, white, slightly shaded with rose, large and excellent; SUNLIGHT, white, margined with faint pink, very large and of good form; WHITE CAMELLIA, white, with greenish centre, of good, sturdy habit.

Yellow- and Orange-flowered: COUNTESS BROWNLOW, rich yellow, very large, dwarf, and floriferous; GOLDEN HIND, yellow, large and excellent; SIR WILFRID LAWSON, deep yellow, of fine form and sturdy habit.

Double-flowered.—*Crimson and Scarlet Shaded:* B. R. DAVIS, rich crimson, very large, compact, and floriferous; DR. NANSEN, intense crimson, free, and of fine form; H. J. INFIELD, scarlet, shaded with salmon, very free, and of good form; LORD CHELSEA, crimson-scarlet, one of the best; LORD DUNRAVEN, crimson-scarlet, large, floriferous, and of good habit; REV. G. T. LITTLE, fiery-crimson, of medium size, excellent.

Rose-coloured: DUCHESS OF MARLBOROUGH (see Fig. 167), light salmon-pink, fine form and erect habit; LUCERNE, salmon-rose, of fine substance; LADY MARY WOOD, salmon-rose, very large, one of the best; MISS THOMPSON, rosy-pink, dwarf and free; NURSE MARY CORNELL, rosy-salmon, very double, compact and free; ROSETTE, carmine-rose, of good size and substance, compact and free.

White-flowered: BLANCHE DUVAL, white, tinted blush, large and free; DIAMOND JUBILEE (see Fig. 168), creamy-white, dwarf bushy habit, very fine; LADY THEODORE GUEST, white, one of the finest, with bold erect habit; MISS EMILY CHILD, white, tinged with pink, very large, of good form and remarkably floriferous; MISS GRIFFITHS (see Fig. 170), a lovely shade, its double flowers having crimped petals, of excellent habit; MRS. PEREIRA (see Fig. 169), white, good form, large, and free.

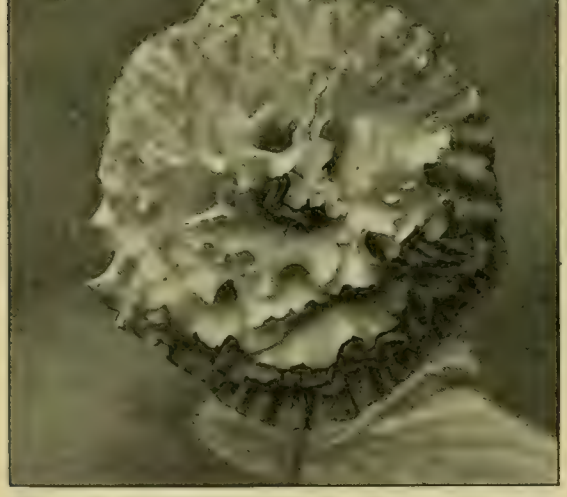


FIG. 170. BEGONIA MISS GRIFFITHS.

Yellow-flowered: MARCHIONESS OF SALISBURY, canary-yellow, large, free, and of bushy habit; MRS. R. CHRISTIAN, soft yellow, large and very double, sturdy, and floriferous; QUEEN OF THE BEGONIAS, orange-yellow, of large size, great substance, and splendid habit.

BEHNIA (a commemorative name). SYNS. *Dictyopsis, Hylonome.* ORD. *Liliaceæ.* A monotypic genus. The species is a greenhouse climber, with the habit of **Myrsiphyllum** (which *see* for culture.)

B. reticulata (net-veined). *fl.* greenish, ¾in. long, in simple or slightly compound cymes from the axils of the upper leaves. *l.* alternate, sessile, ovate, acute, rounded at base, 2in. to 3in. long, firm, green, glossy, with a distinct midrib, and five to seven strongly-marked vertical veins on each side, connected by close cross-veinlets (these have a beautiful effect when the leaves are dried). Stems glabrous, woody, terete, unarmed, copiously branched. South Africa, 1867. (B. M. 5638, under name of *Dictyopsis Thunbergii.*)

BELAMCANDA CHINENSIS. The correct name of the plant described on p. 23, Vol. III., as **Pardanthus chinensis** (which *see*).

BELANTHERIA. A synonym of **Brillantaisia** (which *see*).

BELENIA. A synonym of **Physochlaina** (which *see*).

BELIS. A synonym of **Cunninghamia** (which *see*).

BELLARDIA (of Colla). A synonym of **Microseris** (which *see*).

BELLARDIA (of Schreber). A synonym of **Manettia** (which *see*).

BELLEISLE CRESS. Another name for American orLand Cress *(Barbarea præcox). See* **Cress (American).**

BELLENDENA (named in honour of J. Bellenden Ker, an English botanist). ORD. *Proteaceæ.* A monotypic genus. The species, *B. montana*, is a greenhouse shrub with small, densely racemose flowers and scattered leaves, native of Tasmania. It has been introduced, but is of no particular value from a garden standpoint.

BELLEVALIA. To the species described on p. 179, Vol. I., the following should be added:

B. Heldreichi (Heldreich's). *fl.* of exactly the same colour as those of *Scilla sibirica*; spikes long, produced in pairs from each bulb. *l.* broad. Asia Minor, 1897.

B. romana is a synonym of *Hyacinthus romanus.*

BELLFLOWER, GLAND. *See* **Adenophora.**

BELLIDASTRUM or **BELLIDIASTRUM.** Included under **Aster.** *See* **A. Bellidiastrum.**

BELLINIA. A synonym of **Saracha** (which *see*).

BELLIS. This genus includes seven or eight species of annual or perennial herbs, natives of the Northern hemisphere. Flower-heads heterogamous, solitary, on leafless, often scape-like peduncles; involucre hemispherical or broadly campanulate, the bracts sub-biseriate; receptacle naked; achenes papulose or sparsely hispidulous. Leaves radical or alternate, entire or sinuate-toothed. To the species described on pp. 179-80, Vol. I., the following should be added:

B. integrifolia (entire-leaved). *fl.-heads* about as large as those of the common Daisy; ray florets pale purple or white; involucral bracts acuminate. March to June. *l.* entire, sparsely hairy and ciliated; radical and lower ones spathulate-obovate; upper ones lanceolate or oblong, sessile. Stems 4in. to 12in. high. North America, 1801. (B. M. 3455.)

BELLWORT. *See* **Utricularia.**

BELONITES. A synonym of **Pachypodium** (which *see*).

BELVALA. A synonym of **Struthiola** (which *see*).

BELVISIA. A synonym of **Napoleona** (which *see*).

BELVISIACEÆ. Included under **Myrtaceæ** (which *see*).

BENCOMIA (named in honour of Bencomi, the last King of Teneriffe). ORD. *Rosaceæ.* A small genus (two species) of sparsely branched, greenhouse shrubs, natives of Madeira and the Canary Islands. Flowers dicœcious, in long, axillary, pedunculate spikes; petals wanting. Leaves alternate, impari-pinnate; petioles elongated, sheathing at base; leaflets membranous, petiolulate, oblong, toothed. The species, *B. caudata* and *B. spinosa*, will be found described under **Poterium** (from which this genus has been separated by Bentham and Hooker).

BENGAL ROOT. *See* **Zingiber Cassumunar.**

BENINCASA (named in honour of Count Benincasa, an Italian). ORD. *Cucurbitaceæ.* A monotypic genus. The species is a large, stove, creeping, softly hairy annual, indigenous in tropical Asia, and cultivated for its edible fruits in tropical Africa and America. It is of no great

Benincasa—*continued.*

horticultural value, but is sometimes grown as a curiosity. For culture, *see* **Gourds.**

B. cerifera (wax-bearing). *fl.* yellow, large, monœcious, all axillary, solitary, the males on long peduncles, the females shortly stalked; stamens three, free. *fr.* 1ft. to 1½ft. long, cylindric, with a waxy bloom on the outside. *l.* roundish-reniform, 4in. to 6in. across, deeply cordate at base, palmately five-lobed; petioles 3in. to 4in. long. Tendrils bifid or tritid. Branches rather thick.

BENNETIA. A synonym of **Saussurea** (which *see*).

BENTINCKIA (a commemorative name). SYN. *Keppleria* (of Martius). ORD. *Palmæ.* A small genus (two species, according to the "Flora of British India") of stove, unarmed Palms, natives of Travancore and the Nicobar Islands. Flowers minute, monœcious or polygamous; spadix interfoliolar, branched; spathes many, the two lower ones short and incomplete, the upper ones bifid. Leaves terminal, equally pinnatisect. For culture, *see* **Areca.**

B. ceramica (ceramic). A synonym of *Rhopaloblaste hexandra.*

B. Coddapanna (native name). *fl.*, males scarlet; females lilac or violet; spadix 1ft. to 2ft. long. *l.* 3ft. to 4ft. long; leaflets 2ft. or more in length, 1in. broad, close together, linear, two-keeled, the tip usually bifid. Stem 1in. or more in diameter, 10ft. to 20ft. high, annulate. Travancore.

B. nicobarica (Nicobar Islands). *fl.*, spadix 1½ft. to 2ft. long, decompound, glabrous, the branches and branchlets inserted in woody grooves of the rachis. *l.* 5ft. to 8ft. long; leaflets 6in. to 2ft. long, sessile, linear, coriaceous, obscurely bilobed at apex; petioles short. Trunk annulate, 9in. in diameter, 60ft. to 70ft. high. Nicobar Islands. (R. H. 1896, p. 248, f. 93.) SYN. *Orania nicobarica* (J. B. xiii., 1875, p. 331, f. 19-25).

B. Renda (Renda). A synonym of *Cyrtostachys Renda.*

BENZOIN. Included under **Lindera** (which *see*).

BERARDIA. *Arctio, Arctium,* and *Villaria* are synonymous with this genus.

BERBERIS. Nearly 100 species have been described as such, but not more than fifty are botanically distinct; about fifteen are Asiatic, one is found in Europe and North America, and the rest inhabit the mountainous parts of America, from Oregon to Tierra del Fuego. To the species described on pp. 181-2, Vol. I., the following should be added:

B. angulosa (angular). *fl.* yellow, rather large, the broad outer sepals equalling the inner ones; peduncle exceeding the leaves, stout, curved. *fr.* red, globose- or broadly-oblong, ¼in. to ⅓in. long. *l.* 1in. to 1½in. long, obovate or obovate-lanceolate, puberulous, fascicled, usually entire. Branches erect, leafy. *h.* 4ft. Himalayas, 1844. (B. M. 7071.)

B. Aquifolium Moseriana (Moser's). A variety having light green leaves, tinged with coppery-red. 1895.

B. A. repens (creeping). The correct name of *B. repens.* It is well adapted for covering rockwork or for edging.

B. aristata integrifolia (entire-leaved). A variety having no spines on the edges of the leaves. 1888.

B. aurahuacensis (Aurahuaca). A synonym of *B. Lycium.*

B. Bealei (Beale's). *fl.* yellow, delightfully fragrant, disposed in clustered racemes and sometimes produced as early as the end of January. *l.* yellowish-green, furnished with long, spiny teeth. Japan, 1837. A handsome, erect shrub. (G. C. ser. iii., vol. i., p. 603.) SYNS. *B. nepalensis Bealei, Mahonia Bealii.*

B. Belstaniana (Belstan's). A garden synonym of *B. virescens.*

B. concinna (neat). *fl.* bright orange; outer sepals half as long as the inner ones; peduncles slender, exceeding the leaves. *fr.* large, oblong, pendulous. *l.* obovate, ⅓in. to ⅔in. long, spinous-toothed, deep green above, white beneath. *h.* 1ft. to 3ft. Sikkim Himalaya. A much-branched shrub, often forming appressed cushions. (B. M. 4744.)

B. congestiflora hakeoides (crowded-flowered, Hakea-like). *fl.* golden-yellow, in dense, globose, simple or compound heads ⅓in. to ⅔in. in diameter, which are sessile or pedunculate. Early spring. *l.* 1in. to 2in. long, almost imbricating, sessile or shortly petiolate, orbicular or very broadly oblong, thickly coriaceous, rigidly spinous-toothed, rounded or cordate at base. *h.* 6ft. to 7ft. Chili, 1861. A stout bush. (B. M. 6770.)

B. diaphana (diaphanous). *l.* of a clear green; branches clothed with spines about ⅔in. long. China, 1895. A vigorous tree.

B. elegans (elegant). A synonym of *B. Lycium.*

Berberis—*continued.*

B. Fendleri (Fendler's). *fl.* yellow, with some red bracts at the base of the calyx, disposed in racemes 1in. to 2in. long. Stem and branches purplish, shining. Rocky Mountains, 1888. This species is something in the way of our common Barberry (*B. vulgaris*). (G. & F. 1888, i., p. 462, f. 72.)

B. Fremonti (Fremont's).* *fl.* yellow, sweetly scented; racemes ascending, loosely few-flowered. May and June. *fr.* scarlet, large, dry and inflated when ripe. *l.* pinnate; leaflets in two or three pairs, oblong-lanceolate, with two or three large, spine-tipped teeth on each side. *h* 3ft. to 7ft. Texas, Arizona, 1888. A splendid and quite hardy, evergreen shrub, preferring a sunny, rocky, well-drained situation. (G. & F. 1888, i., p. 496, f. 77.)

B. gracilis (slender). *fl.* deep yellow, borne on bright red pedicels, and disposed in racemes about 3in. long. *l.* shining green, borne on bright red petioles. Branches slender. *h.* 6ft. Mexico. A very pretty, half-hardy species.

B. Hookeri (Hooker's). A synonym of *B. Wallichiana.*

B. Jamesoni (Jameson's). A synonym of *B. Wallichiana.*

B. Lycium (Lycium).* *fl.* yellow; racemes simple or compound, elongated, often corymbose, drooping, longer than the leaves. June. *fr.* violet, ovoid. *l.* almost sessile, sub-persistent, lanceolate or narrow-obovate-oblong, 1¼in. to 2½in. long, coriaceous, mucronate, very spinulose, usually quite entire. *h.* 6ft. to 8ft. Western Himalayas. An erect, rigid shrub. (B. M. 7075.) SYNS. *B. aurahuacensis, B. elegans.*

B. Moseriana (Moser's). A variety of *B. Aquifolium.*

B. nepalensis Bealei (Beale's). A synonym of *B. Bealei.*

B. pruinosa (mealy). *fl.* sulphur-yellow. *fr.* pure white. *l.* having their under-side, as well as the new growths, pure white. Yunnan, 1896. A dwarf shrub.

B. rotundifolia (round-leaved). *fl.* of a brilliant yellow, disposed in corymbs. *l.* entire, veined, rounded, glaucous beneath. Chili. A creeping, strongly spiny shrub.

B. Sieboldii (Siebold's). This species chiefly differs from our common Barberry in its rather paler-coloured and larger flowers, and in the leaves having ciliated margins. Japan, 1880. (G. & F. iii., p. 249, f. 38.)

B. Thunbergii (Thunberg's).* *fl.* numerous, small, ⅓in. to ⅓in. across, drooping; sepals red, half as long as the petals, which are pale straw-coloured suffused with red. April. *l.* in crowded tufts all along the branches, ⅓in. to nearly 1in. long, obovate or spathulate, entire. Spines straight, ⅓in. long. Japan, 1883. A low bush. (B. M. 6646.)

B. virescens (greenish). *fl.* sulphur- or greenish-yellow, ⅓in. in diameter, in fascicles or very short racemes. May and June. *fr.* scarlet or black, narrow-oblong, ⅓in. long. *l.* ⅓in. to 1⅓in. long, tufted, obovate, rounded or apiculate at apex, entire, or the larger ones spinulose-toothed. Branches spreading, divaricating. Sikkim Himalaya, 1850. (B. M. 7116.) SYN. *B. Belstaniana* (of gardens).

B. vulgaris ætnensis (Etna). A dwarf bush with peculiar zigzag branches and stout spines, and producing its flowers freely.

B. v. asperma (seedless). An old but uncommon variety, forming a stout bush, and in autumn bearing a heavy crop of bright scarlet berries.

B. v. foliis-purpureis (purple-leaved). One of the best of dark-leaved shrubs. It should be propagated by cuttings, layers, or division.

Other good varieties are: *amurensis, fructu-albo,* and *macrocarpa.*

BERCHEMIA. SYN. *Œnoplea.* About ten species, natives of Northern India, Java, China, Eastern tropical Africa, and North America, are included in this genus. The following should be added to that described on p. 182, Vol. I.

B. racemosa (racemose). *fl.* small, disposed in terminal panicles, and succeeded by dark brown berries. *l.* oblong or oblong-ovate, sub-acute. Japan and China, 1883. A hardy, climbing shrub.

BERGAMOTTE ORANGE. *See* **Citrus Aurantium Bergamia.**

BERGIA (named in honour of P. J. Bergius, M.D.). SYNS. *Lancretia, Merimea.* ORD. *Elatineæ.* A genus embracing about fourteen species of greenhouse or hardy, prostrate or branched herbs or under-shrubs, allied to *Elatine. B. verticillata* (SYN. *B. aquatica*) has been introduced, but is probably not now in cultivation.

BERIESA. A synonym of **Anredera** (which *see*).

BERKHEYA. SYNS. *Agriphyllum, Basteria, Crocodiloides, Gorteria* (of La Marck), *Rohria, Zarabellia* (of Necker). Including *Stobæa.* About seventy species are included in the genus, all being South African except one, which is found in the tropical region of that continent. To

Berkheya—*continued.*

those described on p. 183, Vol. I., the following should be added:

B. Adlami (Adlam's). *fl.-heads* yellow, 3½in. across, subcorymbose. *l.*, radical ones 1½ft. long, 7in. broad, sinuately lobed and spiny-toothed; upper ones 3in. to 6in. long, spotted with brown beneath. Stem herbaceous, 6ft. high, branched. Transvaal, 1897. This is by far the largest species known. (B. M. 7514.)

BERLANDIERA (named in honour of J. L. Berlandier, a Genoese botanist, who explored parts of Texas and Mexico; he died in 1851). ORD. *Compositæ*. A genus embracing four species of greenhouse or half-hardy, perennial herbs or under-shrubs, natives of the Mexico-Texan region. Flower-heads yellow, heterogamous, radiate, mediocre or rather large, pedunculate; rays in one series; involucre broadly hemispherical; receptacle nearly flat. Leaves alternate, crenate or lyrate-pinnatifid. *B. tomentosa*, the only species in cultivation, requires cool greenhouse treatment, and may be propagated by seeds or by cuttings.

B. tomentosa (downy). *fl.-heads* 1½in. to 2in. across, few in a terminal corymb; ray florets about eight, dull yellow, broadly ovate-oblong; disk green and reddish-brown. May and June. *l.*, lower ones oblong or ovate-oblong, narrowed to a petiole 3in. long; upper ones small, sessile. *h.* 1ft. to 2ft. Southern United States, 1898. A slender perennial, more or less hoary or cottony or glabrate. (B. M. 7680.)

BERREBERA. A synonym of **Milletia** (which *see*).

BERRY-BEARING ALDER. *See* **Rhamnus Frangula.**

BERTEROA. Included under **Alyssum** (which *see*).

BERTOLONIA. Six species, all natives of tropical America, are included in this genus. These stove plants are always admired for their elegant foliage. They are increased by cuttings taken in spring. Of late years some handsome hybrids have been raised, chiefly upon the Continent, and these have, to a certain extent, superseded the species. Some of the best are Comte de Kerchive, Madame Van Geert, Madame Pynaert, Souvenir de Gand, and Van Houttei. To those described on p. 184, Vol. I., the following should be added. *See also* **Gravesia** and **Monolena.**

B. argyræa (silvery). *l.* large, oval, pale green, handsomely veined, reticulated, and spotted with silvery-white, and having numerous white hairs on both surfaces and at the margins. 1894.

B. marmorata. *Eriocnema marmoratum* (L. & P. F. G. i. 27) is identical with this species. *B. Sanderæ* (Sander's) is a seedling form of it, much superior to the type. 1894. SYN. *Eriocnema Sanderæ* (G. M. 1894, p. 658).

BERTOLONIA (of Spinola). A synonym of **Myoporum** (which *see*).

BERTONERILA (a compound of the names *Bertolonia* and *Sonerila*). ORD. *Melastomaceæ*. Under this name several varieties of a hybrid between the genera *Bertolonia* and *Sonerila* are described and figured in the Catalogue of L'Horticole Internationale, Brussels, for 1896.

BESCHORNERIA. According to J. G. Baker, this genus embraces about half-a-dozen closely-allied species, restricted to Mexico. Flowers greenish or reddish, clustered, arranged in simple or panicled racemes. Basal leaves rosulate, ascending, lanceolate, glaucous, scabrous on the margins; stem-leaves bract-like.

B. Toneliana (Tonel's). The correct name of the plant described on p. 184, Vol. I., as *B. Tonelii*.

BESLERIA. About fifty species have been described, natives of tropical America, from Brazil and Peru to the West Indies and Mexico. To those given on pp. 184-5, Vol. I., the following should be added. Several species formerly included here are now referred to **Alloplectus, Brunfelsia, Episcia,** and **Tussacia** (which *see*).

Besleria—*continued.*

B. leucostoma (white-mouthed). *fl.* clustered in the axils; corolla ¾in. long, the tube tawny-orange, laterally compressed beneath near the white limb. April. *l.* oblong or almost ovate-lanceolate, acuminate, crenate-serrated, penninerved. *h.* 1ft. Colombia. SYN. *Hypocyrta leucostoma* (B. M. 4310; F. d. S. 257).

BESOM WEED. *See* **Thlaspis.**

BESSERA. *Pharium fistulosum* (B. R. 1546) is synonymous with *B. elegans*.

BETULA. This genus comprises about twenty-five species, broadly dispersed over Europe, Central and North Asia, and North America. Leaves alternate, toothed or serrated, rarely incised, penniveined. To the species and varieties described on p. 186, Vol. I., the following should be added:

B. acuminata (taper-pointed), of Ehrhart. A synonym of *B. populifolia*.

B. acuminata (taper-pointed), of Wallich. A synonym of *B. alnoides*.

B. alba fastigiata (pyramidal). A variety of free, distinct growth, in habit resembling the Lombardy Poplar.

B. a. japonica (Japanese). A variety with greenish-bronze stems. Japan, 1894.

B. alnoides (Alnus-like). *fl.*, male and female spikes slender, panicled, 3in. to 5in. long, pendulous. *l.* ovate or ovate-oblong, 3in. to 6in. long, cuneate, rounded, or cordate at base, unequally doubly or trebly serrated, pubescent beneath when young. Temperate Himalayas. SYN. *B. acuminata* (of Wallich).

B. alpina (alpine). A synonym of *Alnus viridis*.

B. grandis (large). A synonym of *B. alba*.

B. humilis (dwarf). A synonym of *B. fruticosa*.

B. lanulosa (slightly-woolly). A synonym of *B. nigra*.

B. Maximowiczii (Maximowicz's). *l.* widely oval, cordate at base, toothed, thin and almost membranous, bright dark green above, yellowish-green below, larger than those of any other Birch, being as much as 5½in. long. Bark bronzy-orange, smooth, peeling off in narrow scales and turning ashen-grey. *h.* 30ft. Japan, 1894.

B. Medwediewi (Medwediew's). *fl.*, catkins cylindrical, the males about 1½in. long, the females shorter. *l.* elliptic-ovate, acutely toothed, glabrous, the midrib beneath and the petiole pubescent. Branches glabrous. Trans-Caucasus, 1887. (R. G. 1887, p 384, f. 1-4.)

B. occidentalis (Western). *fl.*, female catkins broadly cylindrical; males 1½in. long. *l.* 2in. to 2½in. long, broadly ovate-rhomboid, acute, of a harsh and dry but not thick texture, slightly lobed and with coarse and sharp serratures, paler beneath but never dotted. Main branches erect, somewhat twiggy, clothed with reddish-brown bark. *h.* 6ft. to 10ft. Western North America.

B. papyracea occidentalis (Western). This variety differs from the type in having deciduous bark and larger and thicker leaves, which are shining above; it comes true from seed. North-west America, 1888.

B. pubescens (downy). A form of *P. alba*.

B. pumila Grayi (Gray's). *l.* roundish, shining green. British Columbia, 1890.

B. pumila-lenta (hybrid). According to the authority quoted below, hybrids between the two species indicated by this name have originated in the Arnold Arboretum. 1895. (G. & F. 1895, p. 243, f. 36; I. H. 1895, p. 243, f. 36.)

B. Raddeana (Radde's). *fl.*, catkins ovoid-oblong, ¾in. to 1in. long. *l.* small, ovate, acutely toothed, pubescent beneath on the nerves and in the angles of the nerves. Young shoots softly pubescent. Caucasus, 1887. (R. G. 1887, p. 384, f. 5-11.)

BEURRERIA. A synonym of **Bourreria** (which *see*).

BHOTAN PINE. *See* **Pinus excelsa.**

BIARUM. Bentham and Hooker included *Ischarum* (*see* p. 201, Vol. II.) under this genus, which thus embraces about a dozen species, found in the Mediterranean region, especially in the Orient. To those described on p. 187, Vol. I., the following should be added:

B. Bovei (Bove's). *fl.*, spathe tube green, the blade greenish outside, deep purple within, lanceolate, three or four times longer than the tube. *l.* varying from ovate to elliptic-oblong, abruptly contracted or narrowed to a long petiole. Anatolia, &c.

B. B. Blumei (Blume's). *l.* ovate-oblong. Asia Minor, 1860. SYNS. *Ischarum crispulum, I. Kotschyi*.

B. carduchorum. *fl.*, spathe sub-sessile, 5in. to 6in. long, green, spotted with purple on the outside, blackish-purple within; spadix blackish, slender, nearly as long as the spathe. *l.* short, spathulate-lanceolate, forming a small cluster from

Biarum—*continued.*

the centre of which the spathe rises. Syria, 1891. SYN. *Arum syriacum* (R. G. 1891, p. 657, f. 124).

B. eximium (choice). *fl.*, spathe tube green, ¾in. long, the limb purplish and minutely spotted outside, dark purple within, 3½in. long, at length revolute; spadix appendage 2½in. to 3in. long; peduncle very short. *l.* ovate-oblong or elliptic-oblong, 1½in. to 3½in. long, narrowed to the petiole. Asia Minor, 1854. SYN. *Ischarum eximium.*

B. Spruneri (Spruner's). *fl.*, spathe purple and greenish, the tube 1½in. long, the limb lanceolate, 3in. to 4in. long; peduncle 1½in. to 2in. long. *l.* spathulate-lanceolate, long-narrowed into the petiole. Greece, &c., 1894. Plant having the habit of *B. tenuifolium.*

BIBIO MARCI. *See* **St. Mark's Fly.**

BICORONA. A synonym of **Melodinus** (which *see*).

BICUSPIDATE. Having two cusps or points. *See* **Cuspidate.**

BIDENS. SYN. *Pluridens.* Nearly 100 species have been described, but probably not more than fifty are entitled to rank as such; they are broadly dispersed over the temperate and warm regions of the globe. To those described on p. 187, Vol. I., the following should be added. It is a perennial, but in this country is best treated as a half-hardy annual.

B. atrosanguinea. The correct name is now *Dahlia Zimapani.*

B. humilis (dwarf). *fl.-heads* yellow, long-pedunculate, solitary; ray florets ¼in. long. Summer. *l.* irregularly bipinnately five-parted; lobes linear-lanceolate; petioles ciliated. Stems almost procumbent. Cotopaxi, 1861.

BIEBERSTEINIA. ORD. *Geraniaceæ.* According to Bentham and Hooker, this genus embraces three species, natives of Central or Western Asia. Flowers yellow or whitish, in rather long, pedunculate racemes, regular; sepals five, imbricated; petals five, hypogynous, imbricated; stamens ten. Leaves stipulate, pinnate or pinnately dissected.

BIENNIALS. From June till August is the usual time to sow Biennials—the earlier the better, as they then stand a chance of making nice plants before winter sets in. For sowing, a border should be chosen with an aspect other than a southern one, so that the seedlings do not receive the full rays of the scorching summer sun; the soil should be moderately rich, deeply dug, and free from weeds. The seeds are best sown in drills, as the hoe can then be used for keeping down weeds, and also for keeping the surface open—a point which is often greatly overlooked in the cultivation of plants of all kinds. After sowing, a good watering should be given through a fine rose, so as not to disturb the seeds, and a thin shading of tiffany or other light material should be thrown over, to keep the soil from drying up too quickly; great care, however, must be taken to remove this as soon as the seedlings break through the soil. When large enough, they should be transplanted into rows a few inches apart; this must be done before they get overcrowded in the seed-bed, and they will then make strong sturdy plants, and will lift with good balls of soil when removed to their permanent quarters.

The time for permanent planting varies from the end of September to March, some preferring to plant in the autumn, because then the weather is usually much milder than in early spring, and if carefully planted they get a good hold of the new soil before winter sets in. On the other hand, those who wait until spring before planting have this advantage, viz., that the plants are all kept together, and if a spell of exceptionally hard weather is experienced they may be much more easily protected by having some dry leaves or other light material thrown lightly amongst them, than if scattered about the beds and borders.

With regard to the after-treatment, uses, &c., of these plants, the remarks under **Annuals** may be taken as applying equally to Biennials. A large number of hardy

Biennials *continued*

annuals are very often treated as Biennials by being sown in the autumn of one year for flowering the following spring.

The following list of Biennials may be of service: *Anchusa capensis* (Cape Forget-me-Not), half-hardy, invaluable for summer-bedding; *Beta Cicla variegata* (Chilian Beet); Dell's Crimson-leaved Beet; *Campanula medium* (Canterbury Bell), the single forms of which are popularly known as Cup-and-Saucer Canterbury Bells, whilst the double ones are known as the Hose-within-Hose Campanulas; *Celsia cretica, Chamæpeuce diacantha* and *C. Casabonæ, Dianthus barbatus* (Sweet William), *Glaucium luteum, Hedysarum coronarium, Humea elegans, Lavatera arborea variegata, Lunaria annua* (*L. biennis*), *Meconopsis nepalensis* and *M. Wallichii, Papaver nudicaule,* Stocks (Bromptons and Queens), *Verbascum olympicum* and *V. phlomoides,* and Wallflowers (*Cheiranthus*).

BIFOLIUM. A synonym of **Maianthemum** (which *see*).

BIFRENARIA. About ten species, natives of Brazil, Guiana, and Colombia, compose this genus. These plants do well when grown in the cool intermediate house under similar conditions to those recommended for Lycastes. To those described on p. 187, Vol. I., the following should be added:

B. atropurpurea (dark purple). *fl.* 2in. across when spread out, fragrant; sepals and petals dull claret-red, stained yellowish in the centre; lip bright rose, suffused with white, incurved at the sides, reflexed at the apex; scapes three- to five-flowered. *l.* oblong-lanceolate, 6in. to 10in. long. Pseudo-bulbs 2in. to 3in. long. Rio de Janeiro, 1823. SYN. *Maxillaria atropurpurea* (L. B. C. 1877).

B. aurantiaca (orange), of gardens. A synonym of *B. inodora.*

B. bella (beautiful). A synonym of *Cœlia bella.*

B. Charlesworthii (Charlesworth's). *fl.* yellow, with a few reddish-brown spots on the lip, about ¾in. long; scape 6in. long, bearing about six flowers. *l.* 9in. long. Pseudo-bulbs quadrangular, 1½in. long. Brazil, 1894. Allied to *B. racemosa.*

B. Hadwenii. The correct name is *Scuticaria Hadwenii.*

B. Harrisoniæ (Mrs. Harrison's). *fl.* 3in. across; sepals and petals creamy-white, large and fleshy, the lateral ones with a spur-like base; lip purple, yellowish at base, purple-veined outside, the inner surface streaked red; scape one- or two-flowered. *l.* solitary, large, oblong-lanceolate, plaited. Pseudo-bulbs pyriform, tetragonal. Brazil. SYNS. *Colax Harrisoniæ, Dendrobium Harrisoniæ* (H. E. F. 120), *Lycaste Harrisoniæ, Maxillaria Harrisoniæ* (B. M. 2927; B. R. 897; P. M. B. ii. 196).

B. H. alba (white). *fl.* white; sepals slightly tinged green, the lower sides of the lateral ones faintly dotted red; side lobes of the lip reddish-purple, veined with deeper red, the middle lobe red-purple, hairy, the spur-like portion greenish-white. Brazil. (R. G. 52, under name of *Maxillaria Harrisoniæ alba.*)

B. H. eburnea (ivory-white). *fl.*, sepals and petals white; lip white, freely striped with crimson; throat yellow, striped purplish-red. April and May. Brazil. A chaste variety. (W. O. A. iii. 100, under name of *Lycaste Harrisoniæ eburnea.*)

B. H. grandiflora (large-flowered). *fl.*, inner surface of the lip wholly purple, except a narrow, yellowish border; spur yellow, with a few bold, purple stripes.

B. H. purpurascens (purplish). *fl.*, sepals and petals of a light plum-purple; front lobe of lip a darker shade of the same colour.

B. inodora (scentless). *fl.* about 3in. across; sepals pale green, oblong, obtuse; petals brighter, but smaller; lip white, yellow, or dull rose-colour, three-lobed, the middle lobe hairy and reflexed, the side ones erect. Otherwise like *B. Harrisoniæ.* Rio de Janeiro, 1839. (R. X. O. i., t. 94, f. 1.) SYN. *B. aurantiaca,* of gardens (W. O. A. ix., t. 386).

B. racemosa (racemose). *fl.* pale, dirty straw-colour, with a white lip, slightly speckled with pale crimson; lateral sepals much elongated at base; raceme few-flowered, pendulous. *l.* solitary, oblong, arched, three-ribbed, shorter than the scape. Pseudo-bulbs small, aggregated. Brazil. SYN. *Maxillaria racemosa* (B. M. 2789; L. B. C. 1318).

B. tyrianthiana (Tyrian). *fl.* reddish-purple, 3½in. across; dorsal sepal erect, the lateral ones broader, connate at base with the hairy foot of the column; lip much smaller, stoutly clawed, three-lobed; scape about three-flowered. *l.* 6in. long, 2in. to 3in. broad. Pseudo-bulbs 3in. long, three-angled. Brazil, 1893. (B. M. 7461; L., t. 446.)

BIG BUD. *See* **Currant-Bud Mite.**

BIGELOVIA (of Sprengel). A synonym of **Spermacoce** (which *see*).

BIGENERIC. A term applied to a hybrid between plants of different genera.

BIGNONIA. This genus embraces about 120 species, all American, and mostly tropical. To those described on p. 189, Vol. I., the following should be added. Several species formerly included here are now referred to **Adenocalymna, Amphilophium, Catalpa, Chilopsis, Distictis, Jacaranda, Macfadyena, Pawlownia, Pithecoctenium, Spathodea, Stereospermum, Tabebuia,** and **Tecoma.**

B. buccinatoria (trumpet-like). The correct name (B. M. 7516) of *B. Cherere.* SYN. *Pithecoctenium buccinatorium.*

B. Catalpa (Catalpa). A synonym of *Catalpa bignonioides.*

B. Chamberlaynii (Chamberlayn's). A synonym of *Anemopægma racemosum.*

B. chrysantha. The correct name is *Tabebuia chrysantha.*

B. leucantha. The correct name is *Dictictis leucantha.*

B. pallida. The correct name is *Tabebuia leucoxyla.*

B. perforata (perforated). *fl.* disposed in a short, terminal raceme; calyx inflated, with torn margins; corolla 2in. long, pubescent outside. August. *l.* trifoliolate and conjugate; leaflets stalked, ovate, pellucid-dotted. Brazil, 1881. Plant tomentose.

B. purpurea (purple). *fl.* bright rose-purple with a pale throat, rather large; limb spreading, the five divisions emarginate; cymes axillary, many-flowered. *l.*, leaflets two or sometimes three, petiolulate, acuminate, 3in. to 4in. long, entire or slightly toothed. South America, reintroduced in 1898. (B. M. 5800; G. C. 1898, ii., p. 393, f. 114.)

B. regalis (royal). *fl.* bright yellow and red, large and exceedingly beautiful. *l.* opposite, elliptic-lanceolate. British Guiana, 1885. A very handsome climber.

B. Rodigasiana (Rodigas'). *l.* bright green, with white variegations, tinted with rosy-red when in a young state. 1893. (I. H. 1893, t. 183.)

B. rugosa (wrinkled).* *fl.* in small, shortly stalked, axillary cymes; corolla primrose-coloured, the tube 2in. to 2½in. long, slightly curved, the limb short, five-lobed. October. *l.* bifoliolate; leaflets 3in. to 4in. long, oblong, acuminate, rounded or cordate at base; petioles 1in. to 1½in. long, ending in a bifid tendril. Caraccas, 1890. Plant hairy. (B. M. 7124.)

B. spectabilis. The correct name is *Tabebuia spectabilis.*

B. venusta. *fl.*, corolla deep orange (not crimson). SYN. *Pyrostegia ignea.*

BILLARDIERA. SYN. *Labillardiera.* The six species forming this genus are all natives of extra-tropical Australia. To the species described on p. 189, Vol. I., the following should be added:

B. cymosa (cymose). *fl.* bluish or violet-purple; corymbs several-flowered, shortly pedunculate or nearly sessile. *l.* usually lanceolate or oblong-linear, sessile or nearly so, obtuse or shortly pointed. Branches more or less twining, or sometimes short and flexuous. 1868.

BILLBERGIA. Including *Helicodea.* According to J. G. Baker's monograph of the *Bromeliaceæ*, this genus embraces about three dozen distinct species, natives of tropical South America. To the species, varieties, &c., described on pp. 190-1, Vol. I., the following should be added:

B. amabilis (lovely). A synonym of *B. vittata.*

B. amœna is a synonym of *B. speciosa.*

B. andegavensis (Angers). *fl.* having a spreading limb, the tube and centre dark red, broadly bordered with violaceous-indigo; bracts bright red; peduncle arching, mealy-white. *l.* broad, obtuse, pale green. 1886. A garden hybrid between *B. thyrsoidea* and *B. Moreli.*

B. aurantiaca (orange). A garden synonym of *Karatas Laurentii.*

B. Bakeri (B. H. 1880, p. 166, t. 8). The correct name of *B. pallescens* (B. M. 6342).

B. Baraquiniana is identical with *B. decora.*

B. bicolor (two-coloured). A form of *B. pyramidalis.*

B. Binoti (Binot's). *fl.*, bracts, stem, &c., red; inflorescence pendulous. *l.* in a rosette, deep green above, the lower portion tinted with reddish-purple; under-surface light green, lined with white. Organ Mountains, Brazil, 1896. Allied to *B. speciosa.*

B. bivittata (twice-striped). A synonym of *Cryptanthus bivittatus.*

Billbergia—*continued.*

B. Blireiana (Blire's). *fl.* sub-sessile; sepals green, pink, and blue; petals green at base, with indigo-blue lobes. A garden hybrid between *B. nutans* and *B. iridifolia.* 1839.

B. Breauteana (Breauté's). A synonym of *B. vittato-Bakeri.*

B. Brongniarti (Brongniart's). A synonym of *Portea kermesina.*

B. Bruanti (Bruant's). *fl.*, calyx very pale green, tipped with blue; corolla very pale yellowish-green; bracts dark red; peduncle rosy, slender, nearly as long as the leaves. *l.* green, obtuse, toothed, forming a cup-like rosette. 1885. A garden hybrid between *B. pallescens* and *B. decora.*

B. Canteræ (Canter's). *fl.* pale greenish-yellow; bracts deep rose-colour, large; inflorescence pendulous, shorter than the leaves. 1897. A handsome plant, belonging to the section *Helicodea.* (R. H. 1897, p. 60.)

B. Cappei (Cappe's). A synonym of *B. vittato-Bakeri.*

B. Croyiana (Croy's). A variety of *B. pyramidalis.*

B. decora (comely). *fl.*, petals greenish, 2in. long, curling up spirally from the base; spike dense, pendulous, simple, 3in. to 4in. long, almost hidden by the large, bright red, oblong-lanceolate bracts; peduncle 1ft. long. January. *l.* eight or ten in a rosette, lorate, acute, 1½ft. to 2ft. long, 2in. broad in the middle, dilated and clasping at base, with transverse, mealy bands, the margins spiny. Para, 1864. (B. H. 1875, p. 221, tt. 13, 14; B. M. 6937.) SYNS. *B. Baraquiniana* (I. H. 1864, 421), *Helicodea Baraquiniana.*

B. decoro-nutans (hybrid). *fl.* few, racemose, about 3in. long; sepals iridescent, reddish at base, blue at the tips, ½in. long; corolla greenish-yellow, the lobes 2in. long, circinately rolled up; bracts rich, bright rosy-crimson, boat-shaped, broadly lanceolate, acuminate; peduncle cylindrical, glabrous, pendulous, 1ft. long. Belgian gardens, 1884. A pretty hybrid. SYN. *B. Windi.*

B. Enderi (Ender's). A synonym of *Quesnelia Enderi.*

B. Euphemiæ (Mme. Morren's).* *fl.* six to twelve in a lax, drooping spike 3in. to 4in. long, nearly sessile, the lower ones subtended by large bracts; sepals reddish, horny; petals about 2in. long, with greenish-yellow claws and bright violet tips; peduncle 1ft. long. April. *l.*, produced ones five or six in a closely convolute rosette, about 1ft. long, 1½in. to 2in. broad, horny, narrowed to an acute point, lepidote-scaly, the margins minutely prickly. South Brazil. (B. H. 1872, tt. 1-2; B. M. 6632.)

B. Euphemiæ-speciosa (hybrid). A hybrid between the species indicated. SYN. *B. Euphemiæ amœna.*

B. farinosa (mealy). A synonym of *B. zebrina.*

B. fasciata (banded). A synonym of *Æchmea fasciata.*

B. Gireoudiana (Gireoud's). *fl.* in an upright spike; calyx rose, faintly bluish towards the tips; petals twice as long as the sepals, blunt, the claw reddish-white at the base, blue at the tip; peduncle white, with carmine-red bracts. *l.* broadly strap-shaped (the inner ones rolled round each other into a wide tube), finely serrated, striped red beneath, deep blackish-purple towards the base. A garden hybrid between *B. Saundersii* and *B. thyrsoidea.*

B. Glaziovii (Dr. Glaziou's). A synonym of *Quesnelia strobilispica.*

B. Glymiana (Glym's). A synonym of *B. Morelli.*

B. horrida (horrid). *fl.* borne in a simple, erect spike, 3in. to 4in. long; petals pale green, tipped with violet, 1½in. long, falcate from the top of the calyx; peduncle 1ft. long. *l.* about ten in a utricular rosette, 1ft. to 1½ft. long, 2in. to 2½in. broad, connivent for the lower 6in. to 9in., deltoid-cuspidate at the tip, the marginal prickles more conspicuous than in any other species. Brazil, 1856. (B. H. 1876, t. 22; R. G. 1859, t. 272.)

B. h. tigrina (tiger-striped). *fl.*, petals narrow, 2in. long. *l.* brown, copiously banded with white on the back.

B. ianthina (violet). A garden synonym of *B. Leopoldi.*

B. intermedia (intermediate). A garden name for *B. vittato-nutans.*

B. Jenischiana (Jenisch's). A hybrid between *B. pyramidalis* and *B. Moreli.*

B. Krameriana (Kramer's). A hybrid between *B. pyramidalis* and *B. speciosa.*

B. leodiensis (Liége). A garden name for *B. vittato-nutans.*

B. Leopoldi (Leopold's).* *fl.* in a dense, oblong spike 6in. to 9in. long; petals violet, 2in. long; peduncle drooping, 1½ft. long, the upper six or eight leaves bright red. Summer. *l.* eight to ten in a rosette, 3ft. to 3½ft. long, 2in. to 2½in. broad, connivent for 1ft., horny, channelled, transversely fasciated with white on the back, the marginal prickles small. Island of Santa Catherina, Brazil, 1847. (B. H. 1871, tt. 1-4.) SYNS. *B. ianthina* and *B. nuptialis* (of gardens), *Helicodea Leopoldi* (I. H., under t. 421).

B. Liboniana. (B. H. 1877, p. 57, t. 34; F. d. S. 1043; L. J. F. t. 197.)

B. macrocalyx (large-calyxed). *fl.* in a drooping raceme 3in. to 4in. long; petals green, tipped with violet-blue, 1in. longer than the calyx; peduncle mealy, 1ft. long, with five or six red bract-leaves. April. *l.* only three or four in a rosette,

Billbergia—*continued.*

lanceolate, 1½ft. to 2ft. long, 2in. broad, horny in texture, connivent for 1ft., white-lepidote on the back, with a few transverse bands. Bahia, 1859. (B. H. 1860, t. 19; B. M. 5114.)

B. Moreli. This is one of the finest species. SYNS. *B. Glymiana* (B. H. 1866, p. 134, t. 11), *B. Wetherilli* (B. M. 4835), but not *B. Moreliana.*

B. Moreliana is a synonym of *B. vittata*, not of *B. Moreli.*

B. Morreniana (Prof. Morren's).* *fl.* borne in a lax, sub-erect spike 3in. to 4in. long, with a red, flexuous rachis; petals green, tipped with violet-blue, 1in. longer than the calyx; peduncle shorter than the leaves, its bract-leaves red. December. *l.* eight to ten in a rosette, connivent in the lower 3in. to 4in., above 1ft. long, 1in. broad, whitish on the back. Origin unknown; it flowered at Kew in 1887. SYN. *B. Reichardti.*

B. nuptialis (nuptial). A garden synonym of *B. Leopoldi.*

B. nutanto-Moreli (hybrid). *fl.* about a dozen; calyx rosy and blue; corolla dark blue; peduncle adorned with numerous rosy bracts, long, slender, arching. 1885. A graceful and ornamental hybrid between *B. nutans* and *B. Moreli*, having the outer leaves narrow, as in *B. nutans*, and the inner ones broader, as in *B. Moreli.* SYN. *B. Worleyana.*

B. pallescens, of Baker (B. M. 6342). The correct name of this is *B. Bakeri.* The *B. pallescens* of Koch (described in Vol. I.) is a variety of *B. speciosa.*

B. pallida is a synonym of *B. speciosa.*

B. Perringiana (Perring's). A hybrid between *B. Liboniana* and *B. nutans*, having leaves like the former species and an inflorescence like the latter. 1890. (R. G. 1890, p. 145, t. 1318.)

B. polystachya (many-spiked). A synonym of *Æchmea distichantha.*

B. Porteana (Porte's).* *fl.*, petals green, lanceolate, above 2in. long, rolling up spirally and disclosing the violet-purple filaments; spike loose, simple, drooping, 6in. to 8in. long; peduncle 2ft. long, with several bright red bract-leaves. August. *l.*, produced ones five or six in a rosette, erect, lorate, 3ft. to 4ft. long, dull green, tinted on the back with claret-purple, and transversely banded with white. Bahia, 1849. Plant stemless. One of the finest species. (B. H. 1876, p. 9, t. 1; B. M. 6670.)

B. pyramidalis. SYN. *Bromelia pyramidalis.*

B. p. bicolor (two-coloured). *fl.* with the two colours (purple and red) not so much blended as in the type. *l.* more distinctly fasciated on the back. Rio Janeiro, 1829. (B. R. 1181.) SYN. *B. bicolor* (L. B. C. 1819).

B. p. Croyiana (Croy's). *fl.* more numerous, and peduncle longer, than in the type; petals red, edged with violet. *l.* erect, with conspicuous dorsal zones. (L. J. F. 413.) SYNS. *Æchmea setigera, B. setosa* (both of gardens).

B. Quesneliana is now correctly known as *Quesnelia cayennensis.*

B. Quintutiana (Quintut's). A synonym of *B. Saundersiana.*

B. Rancougnei (Rancougne's). *fl.*, corolla bluish-green, tipped with indigo, 2in. long; stamens indigo; bracts rosy, woolly-tomentose at the base, together with the ovary and calyx; peduncle 3ft. high. *l.* 3ft. long, 2½in. broad, spreading-recurved, finely toothed. 1884. A hybrid, of which *B. Liboniana* is one of the parents.

B. Reichardti (Reichardt's). A synonym of *B. Morreniana.*

B. rhodocyanea (red and blue), of Lemaire. A synonym of *Æchmea fasciata.*

B. rosco-marginata (SYN. *B. rubro-marginata*) is now correctly known as *Quesnelia rufa.*

B. Sanderiana (Sander's). *fl.* 2in. long; calyx and corolla green, tipped with blue; bracts rosy, with one to three flowers to each; panicle pendulous. December. *l.* erect, broad, green, coriaceous, obtuse, mucronate, armed with stout spines on the margins. South Brazil, 1885. A fine plant. (B. H. 1884, 1, 2.)

B. sanguineum (blood-coloured). *fl.* few on a spike; calyx tube greenish; corolla much longer, scarlet, with violet-purple tips to the segments; bracts scarlet, large, boat-shaped, occurring all along the spike. *l.* about 10in. long, deep green, with tiny grey spots, the marginal spines remote. 1893. Allied to *B. Bruanti.*

B. Saundersiana. *B. Quintutiana* (R. G. 1890, p. 202, f. 49) is identical with this species.

B. setosa (bristly). A garden synonym of *B. pyramidalis Croyiana.*

B. speciosa (showy). The correct name of *B. amœna* (B. H. 1875, tt. 1-4). SYN. *B. pallida. B. pallescens* (of Koch), *B. Thunbergiana*, and *B. Wigtiana* are forms of this species.

B. sphacelata (scorched). A synonym of *Greigia sphacelata.*

B. splendida (splendid). A variety of *B. thyrsoidea.*

B. Thunbergiana (Thunberg's). A form of *B. speciosa.*

B. thyrsoidea. This is scarcely more than a variety of *B. pyramidalis.* (B. H. 1873, p. 295, t. 17; L. J. F. t. 267; P. F. G. iii. t. 74.)

B. t. longifolia (long-leaved). *l.* longer than in the type, and narrowed gradually towards the apex.

Billbergia—*continued.*

B. t. splendida (splendid). *fl.* bright-coloured, more numerous than in the type; bracts broader. Plant more robust. 1883. (L. J. F. tt. 181-2.)

Other forms are *Lemoinei, miniato-rosea, Paxtoni, rhodocyanea* (of gardens, not of Lemaire), and *Schultesiana.*

B. vexillaria (standard-bearing). *fl.* having petals of a brilliant dark violet, obtuse and revolute at the tips. *l.* robust, 1½ft. to 2ft. long. A garden hybrid between a variety of *B. thyrsoidea* and *B. Moreli.* 1889. (R. H. 1889, p. 467, f. 118 and plate.)

B. viridiflora (green-flowered).* *fl.* green, in a lax, ascending or cernuous raceme, 6in. to 12in. long; peduncle 1ft. to 1½ft. long, with bright red, ascending bract-leaves. *l.* twelve to fifteen in a rosette, 1½ft. to 2½ft. long, 1½in. to 2in. broad, connivent for 1ft., sometimes tinged with purple, the marginal prickles very minute. Brazil, 1854. A very distinct species. (B. H. 1874, tt. 1-2; 1876, tt. 20-21; F. d. S. 1019-20.)

B. vittata. *B. amabilis* (B. H. 1874, tt. 1-2), *B. Moreliana* (L. J. F. t. 136), *B. zonata*, and *Tillandsia Moreliana* are identical with this species.

B. v. Rohani (Rohan's). This so-called variety is not distinguishable from the typical plant. 1890. (R. G. 1890, p. 306, f. 60.)

B. vittato-Bakeri (hybrid). *fl.* pale flesh-colour, with violet tips; bracts bright rose, lanceolate; peduncle shorter than the leaves, recurving, glabrous. *l.* 2ft. long, 2in. broad, recurving, lorate, obtuse, slightly channelled, rather thin, bordered with five distant teeth, bright green above, striated and with mealy-white zones below. 1884. A garden hybrid between the species indicated. SYNS. *B. Brocauteana* (R. H. 1885, p. 300), *B. Cappei.*

B. vittato-nutans (hybrid). *fl.* few, in a lax, drooping spike; petals bright violet-blue, twice as long as the calyx; peduncle 1½ft. long, with many large, bright red, ascending bract-leaves. March. *l.* a dozen or more in a rosette, lanceolate, 1½ft. to 2ft. long, recurving from low down. SYNS. *B. intermedia* and *B. leodiensis* (R. G. 563, f. 100-101). There is another form of this hybrid with shorter and stiffer leaves.

B. Wetherilli (Wetherill's). A synonym of *B. Moreli.*

B. Windi (Wind's). A synonym of *B. decoro-nutans.*

B. Wiotiana is a form of *B. speciosa.*

B. Wittmackiana (Wittmack's). A garden hybrid between *B. vittata* and *B. amœna.* 1891. (R. G. 1891, p. 328, f. 69.)

B. Worleyana (Worley's). A synonym of *B. nutanto-Moreli.*

B. zebrina. *B. farinosa* and *Bromelia zebrina* (B. M. 2626) are identical with this species.

B. zonata (zoned). A garden synonym of *B. vittata.*

BILLIOTTIA (of Brown). A synonym of **Agonis** (which *see*).

BILLIOTTIA (of Colla). A synonym of **Calothammus** (which *see*).

BINE. A climbing or twining stem; *e.g.*, Woodbine.

BINECTARIA. A synonym of **Imbricaria** (which *see*).

BIONIA. A synonym of **Camptosema** (which *see*)

BIORHIZA APTERA. *See* **Oak Galls.**

BIPINNATISECT. Having the divisions of a pinnatisect leaf themselves pinnatisect, *i.e.*, cut to the midrib, but with sessile segments.

BIRCHEA. A synonym of **Luisia** (which *see*).

BIRD-OF-PARADISE FLOWER. *See* **Strelitzia.**

BIRDS. Popularly, all Birds are supposed to be beneficial to the gardener and the farmer. That they are not, however, practical observation will tend to show. Many representatives of the Class *Aves* are working in the interests of the gardener; while a larger number are absolutely injurious. Then there is still a third section whose exact position as regards horticulture and agriculture it is not easy to define. They are, perhaps, seed-eaters, or it may be fruit-eaters, and insectivorous—omnivorous, in fact. The point to determine in this case is whether in the aggregate the damage in the one case is not more than counterbalanced by the good in the other—often a most difficult matter for even the most experienced. Here it is only possible to give the most cursory glance at an interesting subject. We can only

Birds—*continued.*

mention the chief amongst the migrants and the permanent dwellers, weighing as far as possible their merits and demerits. As a general rule, insectivorous Birds have a slender and more or less elongated beak; while in the seed-eaters this structure is bulky and short.

Commencing with the *Corvidæ*, we have some very familiar species in the Rook, Magpie, and Jay. The Rook *(Trypanocorax frugilegus)* is on the whole one of the most useful Birds that we have, as it is one of the most persecuted. Generally its food consists of insects—insects, too, of the most destructive kind, such as the grubs of the Skipjack Beetles (Wireworms), Daddy Long-legs (Leather Jackets), and Cockchafers. In the process of searching for these in pastures and lawns, the grass is frequently ripped up and rendered most unsightly; but of the benefit in such cases where insecticides are powerless, there cannot be any doubt. The worst that can be said against the Rook in gardens and orchards is that it will forsake its insect dietary for one of fruit or vegetables, when anything from Walnuts and Pears to young Potatoes will be laid under contribution. The Jay *(Garrulus glandarius)*, a fast disappearing species, is an enemy, as the Bird will make short work of fruit of any kind as well as Peas.

FIG. 171. HAWFINCH.

To the *Sturnidæ* belongs one of the most useful Birds, alike to farmer and gardener, in the Common Starling *(Sturnus vulgaris)*. That it makes a raid upon Cherries is perfectly true, but that it well earns them, by destroying myriads of Wireworms and Leather Jackets, is well known to everyone who has paid attention to the subject.

A very large family, the *Fringillidæ*, next claims attention. In it are found some of the most destructive species—the Bullfinch *(Pyrrhula europæa)* for instance. For Gooseberry and Currant bushes this Bird has a special fondness, denuding them almost entirely of their buds. A somewhat local species is the Hawfinch

Birds—*continued.*

(Coccothraustes coccothraustes) (Fig. 171); but it is a destructive one so far as the fruit-grower is concerned, being especially fond of stone fruits. The Greenfinch *(Chloris chloris)* is one of the commonest Finches, and a seed-eater in the main, though, like many others, it brings up its family upon insects. And similarly of the Chaffinch *(Fringilla cœlebs)*, which generally is voted a nuisance by gardeners. The Goldfinch (*Carduelis carduelis*), one of the handsomest of British birds and now one of the most local, is useful, as it feeds almost entirely upon thistles. The Linnet *(Cannabina cannabina)* must not be regarded unfavourably, although entirely a seed-eater, as it devours vast quantities of injurious weeds, such as Charlock. More destructive than either of the Finches above named is the ubiquitous House Sparrow *(Passer domesticus)*. In fact, it may be said to enjoy the reputation of being the most destructive of all Birds to farm and garden produce. Undoubtedly it takes insects when nesting, yet the damage it does at other times is enormous, as set down by Tegetmeier in his monograph. The Buntings are, on the whole, harmful, though the familiar Yellow Bunting, or Yellow-Hammer *(Emberiza citrinella)*, is one of the least so, as it captures in the summer immense numbers of injurious caterpillars to feed its rather numerous family, frequently six.

Passing over the Larks *(Alaudidæ)* as being seed-eaters, and, so far as the farmer is concerned, doing more harm than good, we come to the *Motacillidæ*. This includes several most useful species in the Wagtails, of which the graceful Dishwasher, or Pied Wagtail *(M. lugubris)*, is the best known. This Bird may frequently be seen working lawns and grass land for insects, on which it entirely subsists. The Yellow Wagtail *(M. campestris)* is a field species, and as industrious an insect forager as its Pied relative.

In the *Certhiidæ*, or Creepers, there is at least one species which ventures near the haunts of men. This is the Tree Creeper *(Certhia familiaris)*, an active little Bird whose method of progression reminds one of the Woodpeckers. It lives upon insects found upon tree-trunks and branches.

The Tits, again *(Paridæ)*, furnish omnivorous species which are amongst the best known of native Birds. Alike in town and country, the Great Tit *(Parus major)* and the Blue Tit *(P. cæruleus)* haunt our very houses; while even the scarcer Coal-Tit *(P. britannicus)* will sometimes venture into suburban gardens and orchards. The Marsh Tit *(P. Dresseri)* is another garden-frequenting species, despite its popular name. In spring those Tits which visit gardens play havoc with the fruit-buds, and particularly those of Gooseberries and Currants. Possibly it may be that the damage done is in the search for insects, of which latter they eat a large number. Later, ripe Pears are often spoiled by the Blue Tit. Occasionally Tits will attack vegetable crops like Peas, when the damage is usually ascribed to other species. The method of attack in such cases should becarefully noted.

One species in the *Laniidæ*, or Shrikes, calls for mention. This is the Red-Backed Shrike, or Butcher Bird *(Lanius collurio)*, a summer visitor, and by no means plentiful. Its method of catching its prey and impaling it upon thorns, is well known to Bird-lovers. Beetles and Wasps are favourite foods, and the Bird must be regarded as highly beneficial to gardeners and farmers.

Amongst the Warblers *(Sylviidæ)* the most familiar are the Whitethroat *(Sylvia sylvia)* (Fig. 172) and the Lesser Whitethroat *(S. curruca)*. Both are practically insectivorous, consuming vast quantities of Aphides and small caterpillars, but at times they will attack small fruits as well as Peas in the pod. Useful, too, is the Willow Warbler *(Phylloscopus trochilus)*, which arrives in late spring, and may be found in gardens industriously searching the foliage of fruit and other trees for insect-

Birds—*continued.*

food. Another near relative, the Chiff-Chaff *(P. minor)*, whose call-note has given rise to the popular name it bears, is no less assiduous as an insect-forager. Frequently the Blackcap *(Sylvia atricapilla)* may be seen in gardens industriously clearing off insects. It is a migrant, and one whose song rivals that of the Nightingale.

The Thrush family *(Turdidæ)* is rich in garden-frequenting species like Song Thrushes, Blackbirds, and Robins; while it also contains that prince of songsters, the Nightingale *(Daulias luscinia)*. The members of this family, at any rate, in the young state, should

FIG. 172. WHITETHROAT.

be readily discriminated from their allies by the fact that they are spotted. Much as we may admire the Blackbird *(Merula merula)* for its period of song (short though it be as compared with the Song Thrush), any good that it may do in keeping down insects is sadly discounted by its destructive propensities in the fruit-garden. It is a fruit-robber of the most pronounced type. Large and small fruits are alike attacked. To Strawberries, Plums, and Gooseberries it is particularly partial; while its boldness could hardly be exceeded. The Song Thrush *(Turdus musicus)*, on the other hand, subsists chiefly upon insects, worms, slugs, and snails. Towards the end of summer, however, orchard and other fruits are attacked—Figs, Apples, Pears, and Plums being most relished. The Bird, however, cannot be regarded in the same light as the Blackbird. The Robin, or Common Redbreast *(Erithacus rubicula)*, is a most useful species; and so is the Common Nightingale, which, during its all too short stay with us, is an insect-feeder. The Wheatear *(Saxicola œnanthe)* (Fig. 173), the Furze-Chat *(Pratincola rubetra)*, and the Stone-Chat *(P. rubicola)*, all belonging to the family under discussion, render the greatest service to farmers.

The Accentors *(Accentoridæ)*, of which the Hedge Sparrow *(Tharrhaleus modularis)* is one of our commonest garden inhabitants, is a species deserving protection, as it destroys quantities of insects in early spring and summer. Its correct name is Hedge Accentor.

Of the *Troglodytidæ*, or Wrens, the most familiar species is the Common Wren *(Anorthura troglodytes)*. This is another ubiquitous species, and one, too, very beneficial

Birds—*continued.*

in gardens, as it is an insect-feeder. Another small Bird held in great esteem is the Common Flycatcher *(Muscicapa grisola)*, of the family *Muscicapidæ*. It is a migrant, and the usual method adopted of swooping down upon some unfortunate insect for which it has been watching is fairly familiar. At other times the insects are taken from the ground position. Aphides and Sawfly larvæ (the latter not relished by many insectivorous birds) are destroyed by the Spotted Flycatcher in vast numbers.

Amongst summer Bird visitors to these islands the advent of none is more eagerly anticipated than that of the Swallows *(Hirundinidæ)*, all of which should be carefully preserved. These include the House Martin *(Chelidon urbica)*, Sand Martin *(Clivicola riparia)*, and the Chimney Swallow *(Hirundo rustica)*. They are entirely insectivorous, and their nests should always be protected.

Mention must now be made of the true Cuckoos *(Cuculinæ)*, one species of which is familiar, at least, by sound. It is a much maligned Bird, but it is one which deserves well of both farmer and gardener. Entomologists are well aware of the caution exhibited by insectivorous birds generally in attacking woolly caterpillars. The Common Cuckoo *(Cuculus canorus)* is, however, one of the exceptions which go to prove the rule. We have seen it clear off the hairy Tiger Moth caterpillars from a Lettuce patch; and also make short work of distasteful Sawfly larvæ like those affecting Currant and Gooseberry bushes.

Belonging to the *Strigidæ* is the Barn Owl *(Strix flammea)*, whose useful qualities cannot be sufficiently well-known, or the Birds would be better protected. They live largely upon mice, but will not hesitate to take the larger rodents like rats. Equally serviceable and worthy of protection is the Kestrel Hawk, or Windhover *(Cerchneis tinnunculus)* (Fig. 174), which feeds upon mice, upon many of the injurious hard-bodied beetles like Cockchafers, as well as upon Grasshoppers. This species may be readily distinguished from the destructive (so far as gamekeepers are concerned) Sparrow-hawk by its method of "hovering" in the air.

Of the Birds now remaining that ought to be mentioned, the Lapwing, or Peewit *(Vanellus vanellus)*, is one of the most useful, as its dietary consists of insects and slugs,

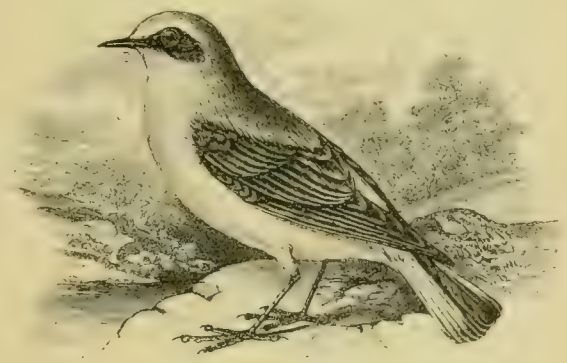

FIG. 173. WHEATEAR.

and flocks of the Birds may be seen in summer searching for food in pasture-lands. Vast numbers of eggs are used for food each spring, and as a big price is set upon them, every encouragement is given to the destruction of the species. Another is the Wood Pigeon *(Columba palumbus)*, which will make short work of

Birds—*continued.*

any Peas in its near neighbourhood, and is therefore undesirable.

Much may be done towards keeping destructive Birds at bay by netting fruit and other trees; Carnation "grass," for the succulent shoots of which Sparrows are extremely fond; and flowers. Black cotton, too, stretched diagonally across rows of Peas and early spring flowers

FIG. 174. KESTREL.

—Wallflowers, Crocuses, Polyanthuses, Primroses, and the like—affords considerable protection, as the Birds dislike getting their wings mixed up with the cotton. In addition it has been found useful to strew lime upon fruit bushes, as this acts as a deterrent if the applications are persisted in.

BIRD'S-BILL. A common name for *Trigonella ornithopodioides.*

BIZARRE. *See* **Carnation.**

BLACK ADIANTUM. *See* **Asplenium Adiantum-nigrum.**

BLACK ARCHES MOTH (*Psilura dispar*). Though in Germany this is one of the worst pests of the forester, yet here, where it is fairly common, it does little, if any, damage. Occasionally it is found on Apple trees, but not in sufficient numbers to warrant measures for its destruction being taken. On the Continent vast sums of money have been spent with a view of devising methods for keeping the pest under, so destructive is it to Firs. As in the case of the Cockchafer in France, an attempt has been made in Germany to destroy the Black Arches by infecting it with fungi, but without any real good resulting. The insect is described and illustrated in Vol. II., under **Liparis.** In Germany the pest is popularly known as "Die Nonne," or "The Nun," as the specific name denotes.

BLACKBERRY (*Rubus fruticosus*). This fruit is so well known that any description is unnecessary. No doubt its freedom of growth in all parts of the country has been the cause of its neglect as a cultivated fruit. When given a good soil and an open situation, and the exhausted or very weak shoots are cut out annually, it is wonderful how great a crop of fine fruit is produced. The best time to prune is immediately after all the fruit is gathered, and in the early spring a mulch of farmyard manure is very beneficial. Nearly all our native large-fruited forms of the Blackberry are equal to any we have procured from America in size of fruit and weight of crop, when grown under similar conditions. In fact, one of the best so-called American varieties (the Parsley-leaved), is really an English one; it is very fruitful and ornamental in foliage. Other good varieties are: Wilson, jun., Kittalinny, and Mitchell's Seedling. All these are excellent, and will succeed almost anywhere, and form a pretty feature in the wild garden, or for covering arbours.

BLACK CURRANT GALL MITE. *See* **Currant-Bud Mite.**

BLACK KNOT (*Plowrightia morbosa*) is a virulent fungoid disease of Plums and Cherries happily not found in this country. In America, however, it is very common, and most difficult to deal with when once it has taken a firm hold. The fungus is well characterised, and eventually produces a knotting of the twigs and branches. The affected portions first swell and then crack, disclosing numberless dark green spores over the parts laid bare. According to Dr. Halsted (who has made the fungus a special study), the young knots and the fresh growth of older ones as the season advances "lose their olive velvety appearance, turn a dark colour, and develop a hard incrustation on the surface. Within the substance of this black and brittle layer many spherical pits are formed, and as winter advances minute sacs are produced upon the wall of the cavity, that toward spring bear each eight oval bodies known as sac-spores. These escape from their long sacs, and pass out through a pore at the top of the cavity, and are then carried by the winds to the surface of a young Cherry or Plum twig, and thus begin another knot, which in course of time produces a new crop of summer and another of winter spores, and thus the disease is preserved and propagated." The treatment consists in light cases in cutting out the "knots" and carefully burning them, but in severe cases the trees have to be rooted up and burned.

BLACK POPLAR. *See* **Populus nigra.**

BLACK RASPBERRY. *See* **Rubus occidentalis.**

BLACK ROOT. *See* **Symphytum officinale.**

BLACK ROT OF CABBAGE and other *Cruciferæ* is of bacterial origin, and the disease is scientifically known as *Pseudomonas campestris*. Though principally found in the United States it has been recorded in this country. Dr. E. F. Smith, in the United States Department of Agriculture, fully describes it in one of the Bulletins (68). Judging from his report, Cabbage and other cruciferous plants may be attacked at any stage. The symptoms may consist of a dwarfing or one-sided growth of the heads, by the absence of any heads, or by the death of the plant. Further, he says: "Occasionally the heads rot and fall off. . . . If the stumps of affected plants are broken or cut across, a brown or black ring will be observed corresponding to the woody part of the stem, this being the part specially subject to the disease. In bad cases this blackening may be easily traced upwards into the centre of the head, and is generally worse on one side In the leaves the symptoms usually begin at the margins, and consist in the yellowing of all affected parts except the veins, which become decidedly brown or black."

Affected foliage should be uprooted and burned, and in bad cases the whole plant should be similarly treated. On no account should cruciferous plants occupy the diseased quarters the next season.

BLACK ROT (or BLACK SPOT) OF TOMATO (*Macrosporium Tomato*). A very common and well-marked fungoid disease, found upon Tomatoes, whether grown under glass or outside. It is more troublesome in the former case than in the latter. As the common name suggests, the chief characteristic is a dark spot, which, as the disease progresses, sinks. Usually the spots appear on the blossom end of the fruit, but they are not confined thereto, or even to the fruit itself, the foliage and stems of the plant being sometimes involved. The fungus gains access to the fruit by means of a rupture in the skin, and spreads very rapidly, and eventually the tissues rot, through the penetration of the dark mycelium. The gardener is generally made aware of the presence of the fungus when the fruits are about one-third grown.

In the case of plants under glass, the chief predisposing causes are too much atmospheric moisture and insufficient ventilation, combined with the use of fresh manure. Directly the disease is noted, all affected fruit (or, in bad cases, plants as well) should be burned, or the trouble will be increased a hundred-fold. The other plants should then be sprayed with sulphide of potassium (1oz. to 3gall. of water) every ten or twelve days for a time. This will prevent it from spreading. Tomato-growers would, however, find it much more profitable to spray early in the season as a preventive measure. Fruits which colour prematurely should especially be regarded with suspicion, as such are frequently affected.

BLACK ROT OF VINES (*Læstadia Bidwellii*). Though frequently found in this country as well as in France, this disease is most prevalent in America, where it constitutes the worst of all Grape foes. The common name is in allusion to the appearance presented by the affected berries. Twigs and foliage are also attacked. Viala, whose investigations in connection with this disease are amongst the most noteworthy, suggests that something by way of prevention might be done by employing stocks which are practically proof against the disease. A similar view is held by Rathay.

The disease is usually first observed on the leaves, for though the young shoots may be also affected, the gardener is more likely to have foliage and fruit under observation.

Black Rot of Vines—*continued.*

The foliage has reddish-brown spots with darker margins, and later the surface is covered with black pustules (pimples). These are pycnidia. By this time the berries are also involved. The first appearance of the disease upon these shows itself, according to Prof. F. D. Chester, "as a light brown spot, caused by the decay of the underlying pulp, this spot increasing in size so as to involve the entire berry. Simultaneous with this change the parts first affected turn black, and become covered with minute black pustules. Finally, the entire berry dries and shrivels, the skin crumpling into angular folds. The entire berry is now uniformly covered with the pustules." When mature, the pycnidia yield stylospores which, if they find a suitable resting-place, germinate, and still further increase the trouble. The disease is probably tided over the winter in ascospores, which remain dormant until the spring of the following year.

The importance of removing and burning all leaves, shoots, and fruits showing the disease, as well as those which have fallen, will at once be apparent.

To check the disease when once it appears, spraying with the ammoniacal solution of copper carbonate (*see* **Fungicides**) is best. This may be employed, if properly made, without injury to either foliage or fruit at intervals of a fortnight. The next season Bordeaux Mixture may be sprayed on before the leaves expand. Certain conditions of Vines and borders predispose to attack in this as in many other fungoid diseases, and the cultivator must be particularly on his guard against the too liberal use of strong manures.

BLACKS. *See* **Athalia spinarum.**

BLACK-VEINED WHITE BUTTERFLY. *See* **Pear Insects.**

BLADDER CAMPION. *See* **Silene inflata.**

BLADDER or POCKET PLUMS. This condition of Plums is due to the presence of a peculiar fungus (*Exoascus pruni*), allied to the destructive Leaf-Curl of Peaches, &c. It is a most insidious disease, and one which materially injures the fruit crop. The gardener is not aware of its presence until the young fruits are developing in May, when, instead of being firm and healthy-looking, and of the normal form, they are distorted, elongated, sometimes wrinkled hollow masses of a yellowish colour. In late summer, these Bladder or Pocket Plums are covered with a glaucous bloom, and finally become rotten, though, perhaps, persistent. This powder consists of asci, or bags, which contain spores ready to be distributed at the proper time. Fruits so affected contain no stones. The area of infection is rapidly spread by means of these spores; and, therefore, the aim of the cultivator must be directed to removing such useless fruits before the spores can be liberated. This will not in itself be sufficient, as the mycelium of the fungus is also present in the branches; hence, therefore, a pruning back of the shoots to the old wood is absolutely necessary, or year by year the trouble will increase, until the trees are rendered quite useless. Where the disease has been known to exist in a garden, or even in a certain neighbourhood, it will be wise to spray in early spring with Bordeaux Mixture, as a precautionary measure.

On the Continent, as well as in America and in this country, the disease is alike very common. For years its cause was ascribed to anything but fungus. At one time the deformed Plums were thought to be due to a gall-making insect as well as to improper fertilisation. Even at the present time the exact method by which healthy trees are infected is not known.

BLADDER RUST, or WEYMOUTH PINE RUST (*Peridermium Strobi*). This is one of the *Uredineæ*, or Rusts, and one, moreover, requiring two host-plants to complete its life-cycle—the Weymouth Pine (*Pinus Strobus*), or an ally like *P. Cembra*, and the Black Currant or other *Ribes*. At one time the latter stage was known to science as *Cronartium ribicolum*. So far the disease has not asserted itself sufficiently in England to cause undue alarm, yet it has been more than once recorded, notably by Dr. Plowright, of King's Lynn, who has done so much towards working out the life-histories of these complex heterœcious fungi. In Germany the disease is commonly met with.

So far as the Pines are concerned, the disease is confined to the twigs and branches on which bladder-like growths of a variable yellow colour appear; these yield spores which need only to come in contact with the leaves of some species of *Ribes* (like the Black Currant, already alluded to) in order to carry on the cycle. On these it forms a yellowish-red Rust yielding uredospores, and later a crop of teleutospores. The disease is of a debilitating nature, particularly to the Pines, whose affected branches die away and the needles are shed. Planters of the Weymouth Pine should exercise the greatest care when introducing new stock, especially that from abroad; and, when suspected, on no account should the two host-plants be kept in proximity—the latter a somewhat difficult matter in the aggregate, as they may be in neighbouring gardens, and thus the disease may be disseminated, as it were, unwittingly.

BLADDER SEED. *See* **Physospermum.**

BLADHIA. A synonym of **Ardisia** (which *see*).

BLAKEA. SYN. *Valdesia*. About sixteen species, natives of Colombia, Venezuela, Peru, and the West Indies, are referred to this genus; but only two have been introduced.

BLANCHING. *See* **Chlorosis.**

BLANCOA (of Blume). A synonym of **Didymosperma** (which *see*).

BLANDFORDIA. According to Bentham and Mueller ("Flora Australiensis"), there are only four distinct species of this genus, all Australian. To the information given on p. 193, Vol. I., the following should be added:

B. aurea is a variety of *B. flammea*.

B. cordata (heart-shaped). A synonym of *Galax aphylla*.

B. Cunninghami is synonymous with *B. grandiflora*.

B. intermedia is synonymous with *B. grandiflora*.

B. nobilis imperialis (imperial). *fl.* bright orange-red, margined with golden-yellow, campanulate, very large. 1890. A fine variety.

BLANKET LEAF. *See* **Verbascum Thapsus.**

BLASTEMANTHUS GEMMIFLORUS. The correct name of *Godoya gemmiflora*.

BLECHNIDIUM and BLECHNOPSIS. Included under **Blechnum** (which *see*).

BLECHNUM. Including *Blechnidium*, *Blechnopsis*, and *Salpichlæna*. This genus comprises about a score species of closely-related Ferns, widely diffused throughout tropical and South temperate regions.

The genus *Blechnum* is composed of mostly handsome-growing plants, of strong habit, very useful for decorative purposes, although there are also included in it several dwarf kinds that are particularly adapted for growing in Fern-cases or in shallow crevices in the rockery.

The pretty little evergreen, *B. Lanceola*, is one of those particularly adapted for planting in Fern-cases, where it thrives admirably, and where the contrast between the bright dark green of the upper surface of its fronds and the continuous central band of deep brown formed by the sori is very conspicuous and attractive.

Blechnum—*continued.*

Like the Lomarias, to which they are closely allied, but from which they differ in not producing separate fertile fronds, the Blechnums are mostly hardy and of rapid growth. They have a particular dislike to water over the fronds, which causes them to turn first brown and then black in a very short time, unless the plants are in a very light, warm, and well-ventilated place, which, to a certain extent, counterbalances the effects of the superfluous moisture by not allowing it to remain on the foliage long enough to injure it. Blechnums will thrive in almost any compost, but their fronds become stouter, and have more consistency, when grown in a mixture of two parts peat, one part loam, and one part sand, with good drainage, taking care that the roots never suffer from want of water. Propagation is usually effected by means of the spores, which are produced in abundance, and which germinate very freely when sown in heat.

FIG. 175. BLECHNUM OCCIDENTALE.

B. occidentale (Fig. 175), a stove species, is one of the best-known and most-appreciated among Ferns of dwarf habit, probably on account of its easy cultivation and the lasting qualities of its elegant fronds, which remain fresh a very long time in water, when used for mixing with cut flowers. Besides, it has for years been used in many establishments for growing amongst orchids, to which it forms a very effective background or undergrowth, the more so that it is a plant never infested by pests of any sort, and that it grows as well in coarse sand, gravel, or moss as in the best compost. To those described on pp. 193-5, Vol. I., the following should be added:

B. corcovadense (Corcova). A variety of *B. brasiliense*.

B. Gilliesii (Gillies'). A synonym of *Lomaria procera*.

B. glandulosum (glandular). A synonym of *B. occidentale*.

B. gracile (slender). A synonym of *B. longifolium*.

B. latifolium (broad-fronded). A synonym of *B. longifolium*.

B. longifolium (long-fronded). This variable stove plant is very well shown at Fig. 176.

B. melanopus (dark-footed). *sti.* dark chestnut-brown. *fronds* lanceolate, 8in. to 9in. long, 2in. to 3in. broad; pinnæ numerous, narrow-falcate, coriaceous, 1½in. long, ¼in. broad, gradually narrowed towards the apex and enlarged at the base, the lowest becoming gradually shorter and more obtuse. *sori* disposed in a

Blechnum—*continued.*

FIG. 176. BLECHNUM LONGIFOLIUM.

continuous line near the midrib. Khasia Hills. Greenhouse. SYN. *Blechnidium melanopus.*

B. nitidum. This useful stove Fern is well shown at Fig. 177.

FIG. 177. BLECHNUM NITIDUM.

B. punctulatum (slightly dotted). A synonym of *Lomaria punctulata.*

B. rugosum (wrinkled). *sti.* 3in. to 6in. long, densely glandular-hairy above, as is the rachis. *fronds* linear-lanceolate, acuminate, about 1ft. long, the surface wrinkled, glandular-hairy; pinnæ with a stalk-like base below, confluent above, oblong, blunt or sometimes abruptly acute, falcately curved. *sori* linear, medial, extending from the base nearly to the apex of the pinnæ. 1884. Greenhouse.

B. Spicant (spiked). A synonym of *Lomaria Spicant.*

B. triangulare (triangular). A synonym of *B. unilaterale.*

Blechnum—*continued.*

B. volubile (twining). *sti.* climbing. *fronds* bipinnate; pinnæ disposed in distant, opposite pairs; pinnules coriaceous, usually four to six on each side, stalked, narrow-lanceolate, 6in. to 12in. long, ½in. to 2in. broad, with an undulated, cartilaginous border. *involucre* broad, membranous, at first wrapped over the fruit, afterwards breaking up into short pieces. Tropical America Stove.

BLECHUM. About four species, natives of the West Indies, Central America, Colombia, and the Philippines, are included in this genus. Flowers rather small, solitary or densely spicate; calyx segments linear-subulate; corolla tube often shortly exserted, the limb spreading, with five rounded, twisted lobes; stamens four, didynamous. Leaves entire or repand-toothed.

BLEEDING. This is most frequently met with in connection with Grape Vines. It is chiefly caused by late pruning, or by an excess of vigour, oftener, however, by the former. To prevent it, pruning should be done as soon as possible after the foliage has fallen, and the Vines given a rest by keeping them as cool as possible for a few weeks. Other plants will also Bleed through pruning at unseasonable times. In the case of ornamental trees it is advisable to cover the wound with coal-tar or grafting-wax.

Another form of sap extravasation takes the form of small, transparent globules on the young growing shoots of Vines. It is not injurious to the health of the plants. It might possibly be injurious if the plant could not thus find an outlet for the excess of sap.

BLEEKERIA. A synonym of **Ochrosia** (which *see*).

BLENNOCAMPA PUSILLA. *See* **Rose Sawflies.**

BLEPHARIS. Including *Acanthodium.* About a score species, natives of tropical and South Africa and the East Indies, are included in this genus. Leaves opposite, membranous or rigid.

BLETIA. SYNS. *Gyas, Thiebautia.* Including *Bletilla.* About a score species have been referred to this genus; they are mostly natives of tropical America, with one Chinese and Japanese. To those described on p. 196, Vol. I., the following should be added. *See also* **Arundina, Brassavola,** and **Calanthe,** for a few species formerly classed hereunder.

B. Godseffiana (Godseff's). This is probably a variety of *B. verecunda,* from which it appears to differ only in having smaller flowers. Brazil (?), 1893.

B. graminifolium (Grass-leaved). A synonym of *Arundina bambusæfolia.*

B. hyacinthina albo-striata (white-striated). A pretty variety, having all the nerves of the leaves white. It will thrive in the cool house. Flowers of the typical plant are shown in Fig. 178.

B. pallida (pale). A synonym of *B. florida.*

B. reflexa (reflexed). *fl.* purple, 1¼in. long, having the lip veined with brown and the keels white. *l.* Grass-like, ¼in. broad. *h.* 1ft. Mexico, 1895.

B. Tankervilliæ (Mrs. Tankerville's). A synonym of *Phaius grandifolius.*

B. Thomsoniana (Thomson's). A synonym of *Schomburgkia Thomsoniana.*

B. Watsoniana (Watson's). *fl.* about 2in. across, borne at the apex of a tall, slender spike; sepals and petals magenta; lip three-lobed, varying from bluish-purple to magenta, with a central white band and a golden disk. Pseudo-bulbs flattish, ridged, broad. 1894. A distinct species.

B. Woodfordii (Woodford's). A synonym of *Phaius maculatus.*

BLETILLA. Included under **Bletia** (which *see*).

BLIGHT. *See* **Apple and Pear Blight.**

BLISTER RUST. *See* **Pine Bark Blister Rust.**

BLITUM. Included under **Chenopodium** (which *see*).

BLOOD is a manure usually rich in ammonia. It is beneficial in the form of a powder as a top-dressing for plants requiring a stimulant to give size and colour to the flowers. In a crude state it cannot be recommended for general use. Much injury has been done to Vines and fruit trees by heavy applications of fresh blood. *See* **Animal Manures.**

BLOODBERRY. *See* **Rivina humilis.**

BLOODWORT. *See* **Sanguinaria canadensis.**

FIG. 178. BLETIA HYACINTHINA.

BLOOMERIA (named in honour of Mr. H. G. Bloomer, Botanical Curator of the Californian Academy of Sciences). ORD. *Liliaceæ*. A small genus (two species) of fine, half-hardy, bulbous plants, natives of California. They differ from *Brevoortia*, *Stropholirion*, and allied genera, in having the perianth segments free to the base, as in **Allium** (which *see* for culture).

B. aurea (golden). *fl.* golden-yellow, disposed in a spreading, many-flowered umbel; perianth rotate, 1in. in diameter, the segments linear-oblong; scape slender, about 1ft. long. July. *l.* solitary, 1ft. long, very narrow-linear. Bulb as large as a Hazel-nut. California, 1869. (G. C. 1896, xx., p. 687, f. 119.) SYN. *Nothoscordum aureum* (B. M. 5896).

B. Clevelandi (Cleveland's). This resembles *B. aurea*, but the flowers are smaller, the stamens are shorter in proportion to the perianth, and the scape is slenderer. 1896. (G. C. 1896, xx., p. 687, f. 120.)

BLUEBELL, NEW ZEALAND. *See* **Wahlenbergia saxicola.**

BLUEBERRY. *See* **Vaccinium Myrtillus.**

BLUE BONNETS. *See* **Scabiosa succisa.**

BLUE BUTTONS. *See* **Scabiosa succisa.**

BLUE COWSLIP. *See* **Pulmonaria angustifolia.**

BLUE CURLS. *See* **Trichostema.**

BLUE-EYED GRASS. *See* **Sisyrinchium.**

BLUE JACK. *See* **Quercus cinerea.**

BLUE PALMETTO. *See* **Rhapidophyllum Hystrix.**

BLUE VERVAIN. *See* **Verbena hastata.**

BLUMENBACHIA. About a dozen species, all American, are included in this genus. To those described on pp. 196-7, Vol. I., the following should be added:

B. lateritia (brick-red). The correct name of *Loasa lateritia* (B. M. 3632; B. R. 1838, 22).

B. multifida (much-cleft). *fl.* white, with a red and yellow centre, bibracteate; petals hispid. July. *l.* palmately lobed and bipinnatifid. Otherwise resembling *B. insignis*. Buenos Ayres, 1826. (B. M. 3599.)

BLUMENBACHIA (of Koeler). A synonym of **Sorghum** (which *see*).

BLUMIA. A synonym of **Sarauja** (which *see*).

BLUSH ROSE. *See* **Rosa indica.**

BOAT-LIP ORCHID. *See* **Scaphyglottis.**

BOBARTIA. According to J. G. Baker, this genus comprises eight species, natives of Cape Colony. Flowers pale yellow, fugitive, more than one in a spathe; perianth-tube none or very short, the segments spreading; stamens inverted at the base of the perianth; clusters fascicled, rarely single, usually overtopped by a single bract. Leaves rigid, terete or ensiform.

BOCCONIA. This genus consists of about five species, natives of tropical America and China. To those described on p. 197, Vol. I., the following should be added:

B. microcarpa (small-fruited). *fl.* of a warm bronzy tint, disposed in a plume-like panicle, not unlike the Venetian Sumach in the early summer. *l.* much as in *B. cordata*. *h.* 9ft. Northern China, 1896. (R. H. 1898, p. 362, f. 125.)

BŒA. *See* **Bæa.**

BŒBERA is a synonym of **Dysodia** (which *see*).

BŒHMERIA. SYNS. *Duretia*, *Splitgerbera*. This genus embraces about forty-five species, broadly dispersed, mostly tropical. To that described on p. 197, Vol. I., the following variety should be added:

B. nivea candicans (whitish). *l.* the same colour on both sides, or the young ones at first whitish beneath. SYN. *B. tenacissima*.

B. tenacissima (very tenacious). A synonym of *B. nivea candicans*.

BŒNNINGHAUSENIA (named in honour of C. F. von Bœnninghausen). ORD. *Rutaceæ*. A monotypic genus. The species (*B. albiflora*) will be found described on p. 337, Vol. III., under its old name, **Ruta albiflora.**

BOG MOSS. *See* **Sphagnum.**

BOG RHUBARB. *See* **Petasites vulgaris.**

BOG VIOLET. *See* **Pinguicula vulgaris.**

BOILERS. *See* **Heating.**

BOLBITIS. Included under **Acrostichum** (which *see*).

BOLDEA. A synonym of **Peumus** (which *see*).

BOLDOA (named after Baltasar Manuel Boldo, a Spanish botanist, who collected in Cuba at the end of the eighteenth century). SYN. *Salpianthus*. ORD. *Nyctagineæ*. A small genus (two species) of stove, tuberous herbs, natives of Mexico, one being also found in Cuba. Flowers small, in cymose heads or racemes. Leaves alternate, petiolate, deltoid- or trapezoid-ovate, obtuse, entire. *B. lanceolata* has been introduced, but is not of much horticultural value.

BOLE. The body of a tree.

BOLIVARIA. A synonym of **Menodora** (which *see*).

BOLLEA PULVINARIS. This does not appear to differ from **Zygopetalum cœleste** (which *see*).

BOLTONIA. There are about a dozen species of this genus, natives of North America and North and sub-tropical Asia. Flower-heads heterogamous, paniculate or solitary; involucre hemispherical, the bracts in few series;

Boltonia—*continued.*

receptacle convex or conical. Leaves alternate, entire or deeply toothed. To the species described on pp. 198-9, Vol. I., the following should be added:

B. diffusa (diffuse). The correct name of *B. asteroides* (of B. M.).

B. latisquama (broad-scaled). *fl.-heads* bluish-violet; involucral scales spathulate or obovate, mucronate or cuspidate. Autumn. *l.* linear-lanceolate. *h.* 3ft. to 5ft. North America, 1879.

BOLTS. *See* **Trollius europæus.**

BOMAREA. SYNS. *Danbya, Vandesia.* Including *Collania* (of Herbert). According to J. G. Baker, this genus embraces about seventy-five species, natives of Mexico and South America. In *Alströmeria* the three inner segments are unequal, while in *Bomarea* they are equal. To the species, &c., described on p. 200, Vol. I., the following should be added:

B. acutiflora. This differs from *B. edulis* in its short, simple or at most two-flowered peduncles, and more brightly-coloured (yellow) inner perianth segments. (B. M. 3050, 3871; S. B. F. G. ser. ii. 77.)

B. andimarcana (high Andes). *fl.*, perianth 1½in. to 2in. long; segments equal, the outer ones much tinged with red, the inner ones yellowish-green. *l.* crowded, sessile, erecto-patent, 3in. to 5in. long. Stems much decurved at top. High Andes of Peru, 1846. SYN. *Collania andimarcana* (B. M. 4247).

B. Bredemeyeriana (Bredemeyer's). A synonym of *B. multiflora.*

B. Caldasiana. SYN. *Alströmeria Caldasii* (B. M. 5442).

B. chontalensis is a variety of *B. edulis.*

B. densiflora (dense-flowered). A synonym of *B. tomentosa.*

B. edulis. SYNS. *Alströmeria edulis* (A. B. R. 649), *A. Salsilla* of Gawler (B. M. 1613). *B. chontalensis* is a variety of this species.

B. e. ovata (ovate). *fl.* larger than in the type. *l.* broader, more rounded at the base, pubescent beneath. SYN. *Alströmeria ovata* (B. M. 2846).

B. Jacquesiana (Jacques'). *fl.*, perianth segments equal, 1½in. to 2in. long, the outer ones bright pink, spotted towards the edge, oblong-spathulate, the inner ones greenish-white, spotted all over the blade, unguiculate in the lower half; umbel drooping six- to twelve-rayed. *l.* petiolate, oblong, acute, 4in. to 6in. long, 2in. broad. Stems elongated, sarmentose, dark brown. Brazil, 1875. SYN. *Alströmeria Jacquesiana* (F. d. S. 182).

B. Kalbreyeri (Kalbreyer's). *fl.* pedicellate, in large, terminal umbels, the three outer segments brick-red, about 1in. long, oblong-spathulate, the three inner ones orange-yellow, spotted red, longer than the outer ones, obovate-cuneate. *l.* shortly stalked, oblong, acuminate, glabrous above, downy beneath. Colombia, 1883. (R. H. 1883, p. 516.)

B. multiflora (many-flowered). *fl.* twenty to forty in a dense umbel; perianth segments nearly equal, the outer ones tinged with red, oblanceolate, 1in. long, the inner ones reddish-yellow, copiously spotted with claret-brown. September. *l.* lax, petiolate, oblong, acute, 3in. to 4in. long. Stems sarmentose, finely pubescent. Venezuela and Colombia, 1829. SYN. *B. Bredemeyeriana* (F. d. S. 2316).

B. patacoensis (B. M. 6692) is the correct name of *B. patococensis.*

B. rosea (pink). *fl.* few or many in a usually simple umbel; perianth segments equal, about 1in. long, the outer ones pale red, tipped with green, oblanceolate, the inner ones greenish-yellow, spotted, obovate-unguiculate. *l.* lax, petiolate, oblong-acute, 3in. to 4in. long, thin, glaucous and pubescent beneath. Stems elongated, sarmentose. Andes of Peru, &c. SYN. *B. simplex* (B. M. 3863).

B. Salsilla. SYN. *Alströmeria oculata* (B. M. 3341; L. B. C. 1851). The *B. Salsilla* of Gawler is identical with *B. edulis.*

B. simplex (simple). A synonym of *B. rosea.*

B. sororia (sisterly). *fl.* about twenty in a loose umbel; outer segments of the perianth rosy, spotted with carmine, a little shorter than the inner ones, which are green, spotted with brown. *l.* ovate, acuminate, pubescent beneath. South America, 1892. This resembles *B. edulis.* (I. H. n. s. t. 145.)

B. tomentosa (downy). The correct name of *Alströmeria densiflora.* SYN. *B. densiflora.*

B. vitellina (egg-yolk-colour). *fl.* of a rich, deep orange-yellow, narrowly-campanulate, 2in. long, numerously disposed in large, drooping, umbellate cymes; outer and inner perianth segments unequal in length. *l.* ovate-oblong, acute. Stems smooth. Colombia, 1882. A very beautiful, tuberous-rooted climber, adapted for conservatory decoration. (G. C. n. s., xvii., p. 143.)

B. Williamsiæ (Mrs. Rosa Williams') is the correct name of *B. Williamsii.*

BOMBARRA GROUND NUT. *See* **Voandzeia subterranea.**

BOMBAX. This genus embraces ten species, natives of tropical Asia, Africa, and America.

B. Gossypium (Gossypium). A synonym of *Cochlioperma Gossypium.*

BOMBUS LUCORUM. *See* **Humble Bee.**

BOMBUS TERRESTRIS. *See* **Humble Bee.**

BOMBYCINA. *See* **Moths.**

BONAPARTEA (of Ruiz and Pavon). Included under **Tillandsia** (which *see*).

BONAPARTEA (of Willdenow). Included under **Agave** (which *see*).

BONAVERIA. A synonym of **Securigera** (which *see*).

BONELLIA. A synonym of **Jacquinia** (which *see*).

BONES. Bone-meal is valuable for all crops in which lime is a prominent constituent, as, for instance, the Vine, all stone fruits, Apples, Pears, and most vegetable crops. It is also beneficial if mixed at the rate of 2lb. of Bone-meal to one barrow-load of compost for Strawberries in pots, Chrysanthemums, and many other plants. What are termed 1in. and ½in. Bones are only suitable for fruit-tree borders, as they are slow in action. *See* **Animal Manures.**

BONJEANIA. Included under **Dorycnium** (which *see*).

BONNETIA. SYN. *Kiesera.* Five species, all South American, are referred to this genus.

BONNETIA (of Schreber). A synonym of **Mahurea** (which *see*).

BONNINGHAUSIA. A synonym of **Chætocalyx** (which *see*).

BONPLANDIA (named in honour of Aimé Bonpland, a French naturalist). SYN. *Caldasia.* ORD. *Polemoniaceæ.* A monotypic genus. The species, *B. geminiflora* (B. R. 92, under name of *Caldasia heterophylla*), is a glandular-pilose, stove herb or under-shrub, native of Mexico, with violet flowers and undivided leaves. It is probably not now in cultivation.

BONTIA (of Linnæus). A synonym of **Avicennia** (which *see*).

BOOPHANE, or BOOPHONE. *See* **Buphane.**

BOOPIDEÆ. Included under **Calycereæ** (which *see*).

BOPUSIA. A synonym of **Graderia** (which *see*).

BORAGO. SYN. *Borrago.* About half-a-dozen species, natives of the Mediterranean region (one being also found elsewhere), are comprised in this genus. To those described on p. 201, Vol. I., the following synonyms should be added:

B. orientalis (Oriental). A synonym of *Trachystemon orientalis.*

B. zeylanica (Cingalese). A synonym of *Trichodesmia zeylanicum.*

BORASSUS. SYN. *Lontanus.* According to Bentham and Hooker, this genus is monotypic, *B. æthiopicum* being regarded as synonymous with *B. flabellifer* (also known as *B. flabelliformis*).

BORDEAUX MIXTURE, or BOUILLIE BORDELAISE. This is by far the most effective fungicide introduced. As the name above adopted denotes, it had its origin in the City of Bordeaux, having been discovered by Millardet, in 1885. On the Continent, and also in America, it has been extensively and successfully employed by fruit-growers to battle with many of the most insidious diseases to which the softer fruits, such as Grapes, are liable. In this country, so far, its merits

Bordeaux Mixture—*continued.*

have not been so widely appreciated as they deserve, considering its effectiveness, ease of application, and cheapness. The preparation consists of a solution of copper sulphate and quicklime, with occasionally, to increase the adhesiveness, molasses or soft soap. Several strengths have been advocated to suit different plants and the foliage or fruit at various stages. In the young and tender stage of either foliage or fruit the solution should be weaker than when either is more advanced. On account, however, of the disfiguring effect it has upon fruits required for either market or the table, the fungicide should not be employed, say, within a month or six weeks of the time of its being required. In the case of ornamental plants it is better to use one of the clear fungicides, simply on account of the effect produced. *See* **Fungicides.**

For general purposes, the best formula is: Copper sulphate, 6lb.; unslacked lime, 4lb.; water, 50gall. Almost equally good results have been obtained by further reducing the copper sulphate to 4lb. Professor Galloway, of the United States Department of Agriculture, gives simple but very minute directions for the preparation of Bordeaux Mixture as follows: In a barrel place 25gall. of water. Weigh out 6lb. of copper sulphate, then tie the same in a piece of coarse sacking, and suspend it just beneath the surface of the water. By tying the bag to a stick, laid across the barrel, no further attention need be given In another vessel slack 4lb. of lime, taking care to form a paste free from grits or lumps; this is best done by placing the lime in an ordinary water-pail, and adding at first, say, from 1 quart to 3 pints. When the lime begins to crack and crumble, and the water to disappear, another quart or more of water should be added, taking care that at no time the lime gets too dry. Towards last a considerable quantity of water will be required; but if added slowly by degrees, a perfectly smooth paste will result, if the lime used be of good quality. When the lime is slacked, add sufficient water to bring the whole up to 25gall. When the copper sulphate is entirely dissolved and the lime cool, the lime-milk and copper sulphate solution should be poured slowly together into a barrel holding 50gall., first thoroughly mixing the lime-milk. A final stirring for a few minutes with a broad wooden paddle completes the process.

To determine whether the preparation is safe to apply to tender foliage, Professor Galloway recommends the following test: Insert the blade of a penknife in the mixture, allowing it to remain for at least one minute. If the polished steel assumes the colour of copper-plate, the mixture is unsafe, and more lime must be added. If, however, the blade remains unchanged, the mixture has been correctly prepared.

If the Bordeaux Mixture cannot all be used after preparation, extra care will be necessary on its employment subsequently to see that it is well stirred. After a time the useful constituents are precipitated, leaving a clear liquid of no value as a fungicide. Paris Green is sometimes added to the Bordeaux Mixture with a view to combining an insecticide with a fungicide.

BORKHAUSENIA. A synonym of **Teedia** (which *see*).

BORONIA. Including *Cyanothamnus.* Australia is the home of this genus, which embraces about fifty species. Only one species and its variety call for addition to those described on p. 203, Vol. I.

B. Fraseri (Fraser's). (B. M. 4042.) The correct name of *B. anemonifolia* of P. M. B

B. heterophylla (variable-leaved). *fl.* pink; sepals very short; petals about ¼in. long, imbricated; peduncles axillary, one-flowered, thickened under the flower. April. *l.* either simple and linear, 1in. to 2in. long, or pinnate, with three to five

Boronia—*continued.*

linear leaflets on an elongated, common petiole. Branches slender, numerous. 1837. A tall, glabrous shrub.

B. h. brevipes (short-stalked). *fl.* bright scarlet, whorled at the leaf axils, usually in fours or sixes, drooping, sub-globose; petals concave, sub-acute. 1881. (B. M. 6845.)

B. pulchella (rather pretty). The correct name of *B. Drummondii.*

B. tetrandra is synonymous with *B. pulchella.* (L. & P. F. G. i. 35, t. 5.)

BORRAGINOIDES. A synonym of **Trichodesma** (which *see*).

BORRAGO. A synonym of **Borago** (which *see*).

BORRICHIA (named in honour of Olaf Borrich, of Copenhagen, who wrote on medicinal plants at the end of the seventeenth century). SYNS. *Adelmannia, Diomedea.* ORD. *Compositæ.* A small genus (three to five species) of greenhouse, evergreen shrubs, natives of the West Indies and the neighbouring coast of North America. Flower-heads yellow, heterogamous, radiate. Leaves opposite, entire, rather thick. Three species have been introduced (under the name *Diomedea*), but it is doubtful if either of them is still in cultivation.

BOSSCHERIA. Included under **Ficus** (which *see.*)

BOSSIÆA. Including *Lalage.* Thirty-four species are referred here by Bentham in the "Flora Australiensis." To the species described on pp. 203-4, Vol. I., the following should be added. *See also* **Scottea.**

B. dentata (toothed). The correct name of *Scottea dentata.*

B. disticha (two-ranked). *fl.* solitary or two together; standard twice as long as the calyx. May. *l.* distichous, ovate or oblong; very obtuse but often minutely mucronate, ¼in. to ⅜in. long, sprinkled with appressed hairs. *h.* 2ft. 1840. (B. R. 1841, t. 55.)

B. heterophylla (variable-leaved). *fl.*, standard very broad and twice as long as the calyx; pedicels shorter than the leaves. September. *l.* distichous, often distant, ⅜in. to 1in. long, the lower ones ovate or nearly orbicular, the upper ones becoming gradually narrower. Branches erect or ascending. *h.* 1ft. to 2ft. 1792. (L. B. C. 271.) SYNS. *B. lanceolata* (B. M. 1144), *Platylobium lanceolatum* (A. B. R. 205), *P. ovatum* (A. B. R. 266).

B. lanceolata (lanceolate). A synonym of *B. heterophylla.*

B. ornata (ornamental). *fl.* usually two or three together; standard often ⅜in. in diameter. April. *l.* broadly ovate (almost cordate) to narrow-lanceolate, ⅜in. to 2in. long, flat, loosely pubescent beneath. *h.* 1ft. to 2ft. 1830. SYN. *Lalage ornata* (B. 141; B. R. 1722).

B. o. hoveæfolia (Hovea-leaved). *l.* oblong-lanceolate, with somewhat recurved margins. 1841. SYN. *Lalage hoveæfolia* (P. M B ix., p. 171).

B. paucifolia (few-leaved). A synonym of *B. rufa foliosa.*

B. prostrata (prostrate). The correct name of *B. linnæoides.* (B. M. 1493.)

B. rotundifolia is probably a luxuriant variety of *B. rhombifolia.*

B. rufa (rufous). *fl.* solitary or clustered, proceeding from leafless nodes; standard broad, more than twice as long as the calyx. August. *l.* (when present) obovate or oblong, ¼in. to ⅜in. long, very obtuse. Branches flattened, sometimes spiny, bordered by narrow wings, which disappear in leafy specimens. *h.* 6ft 1803. (L. B C. 1119.)

B. r. foliosa. The correct name of *B. foliosa.* SYN. *B. paucifolia* (B. R. 1843, t. 63).

B. r. virgata (twiggy). Branches elongated, more or less leafy, not spiny 1841. SYN. *B. virgata* (B. M. 3896).

B. rufa (of Maund). A synonym of *B. ensata.*

B. virgata (twiggy). A form of *B. rufa.*

BOSTRYCHUS DISPAR. *See* **Apple-Bark Beetle.**

BOSTRYCHUS DOMESTICUS. *See* **Scolytidæ.**

BOSWELLIA. SYNS. *Libanus, Plœsllia.* There are three or four species of this genus, natives of Africa and Central India. To those described on p. 204, Vol. I., the following should be added:

B. Carterii (Carter's). *fl.* whitish, in simple, axillary racemes. *l.* imparipinnate; leaflets opposite, eight to ten on each side, ovate, 1¼in. long, undulated, glabrous or pubescent. *h.* 12ft. to 20ft. Arabia, &c.

B. glabra is regarded by Hooker as a variety of *B. serrata.*

BOTANY may be described as the Science which treats of Plants: their structure, functions of their parts, qualities, uses, nomenclature, and geographical distribution. Accordingly it is divided into Structural, Physiological, and Systematic. From a very early date Botany has been studied, but it was not until the time of Theophrastus (B.C. 324) and Pliny that any serious consideration was given to the subject. The Science progressed but slowly, notwithstanding the introduction of the microscope, until Ray, in 1686, issued his "Systema Plantarum." To Linnæus, however, belongs the greatest credit, for his "Systema Naturæ," in which the Artificial System of Botany was propounded. Later he, in part, worked out a natural one, which was modified by Jussieu, and afterwards by De Candolle, Lindley, and Bentham and Hooker, whose monumental labours are embodied in the "Genera Plantarum" of the present day.

BOTHERBE. A synonym of **Calydorea** (which *see*).

BOTHRIOCHILUS. A synonym of **Cœlia** (which *see*).

BOTRYADENIA. A synonym of **Myriactis** (which *see*).

BOTRYANTHUS. Included under **Muscari** (which *see*).

BOTRYCERAS (from *botrys*, a bunch, and *keras*, a horn; in reference to the incurved, pectinate branches of the female inflorescence). SYNS. *Daphnitis*, *Laurophyllus*. ORD. *Anacardiaceæ*. A monotypic genus. The species, *B. laurinum*, is a greenhouse, evergreen tree or shrub, native of South Africa. It has been introduced, but is probably not now in cultivation.

BOTRYCHIUM contains some very curious plants, all deciduous; but they are seldom seen in cultivation, probably on account of the difficulties experienced in keeping them through the winter, when they should not on any account be allowed to get dry, or death will speedily and assuredly ensue. They are of little use as pot-plants, but their fertile fronds have a very pleasing appearance among other Ferns when grown in the rockery, in which case they should be planted in some naturally damp nook where they are not likely to be disturbed, and where constant moisture may be secured for them while at rest. The difficulty in taking them up consists in getting the crowns with their roots, as they are generally found to be deeply imbedded in the ground.

To induce Botrychiums to grow in a Fernery, they should be moved with about a square foot of the turf in which they are growing naturally, and as much of depth of the soil undisturbed. They like to have their roots covered with turf, though they should not be overshadowed by other vegetation. The plants succeed best in a compost of sandy loam and only a small portion of peat, and perfect drainage is essential. Propagation may be effected by division of the crowns. There is no record of seedlings having been raised artificially.

B. lanuginosum (woolly). A variety of *B. virginianum*.

B. virginianum lanuginosum (woolly). *sterile segments* slightly hairy. *fertile peduncle* rising from the centre of the barren frond, which the panicle scarcely overtops.

BOTRYODENDRON. A synonym of **Meryta** (which *see*).

BOTRYOID. Bunch-like; having the form of a bunch of Grapes.

BOTRYTIS. Under this generic heading were at one time grouped a number of very destructive fungi whose spores are produced in clusters resembling miniature bunches of Grapes. Present-day plant pathologists now regard it as but a form-genus—one phase, in fact, in the life-history of the plants. Some of the most familiar of these *Botrytis* fungi are: the species of *Sclerotinia*, giving rise to the very destructive Lily disease—*B. cinerea*, a form of the much-dreaded *Sclerotinia fuckeliana* of the Vine, &c.; *B. pæoniæ*, a form of *S. pæoniæ*, responsible for the disease of Pæonies,

Botrytis—*continued.*

characterised by a sudden collapse of the stems and the presence of a greyish-white mould; *B. galanthina*, a form of *S. galanthina*, which attacks Snowdrops; *B. Douglasii*, a form of *S. Douglasii*, found upon the shoots of the Douglas Fir; and several others.

BOTTIONEA THYSANOTOIDES. The correct name of **Trichopetalum stellatum** (which *see*).

BOUCEROSIA. SYNS. *Apteranthes*, *Desmidorchis*, *Hutchinia*. About a dozen species have been recorded; they are found in India, Arabia, North Africa, Spain, and Sicily. In addition to those described on p. 205, Vol. I., *B. incarnata* (SYN. *Podanthes incarnata*) and *B. mammillaris* (SYN. *Stapelia pulla*, B. M. 1648) have been introduced, but are probably lost to cultivation.

BOUCHEA. Including *Chascanum*. This genus comprises sixteen or seventeen species, natives of the warmer parts of America, tropical and South Africa, and the western provinces of India.

BOUGAINVILLÆA. SYN. *Josepha*. This genus comprises seven or eight species of shrubs or small trees, rarely sarmentose or somewhat climbing, natives of tropical and sub-tropical South America. Flowers inserted below the middle of the bracts; perianth tubular, slightly curved; inflorescences solitary or fascicled, axillary or terminal. Leaves alternate, petiolate, rounded-ovate or elliptic-lanceolate, entire. To the species described on pp. 205-6, Vol. I., the following should be added:

B. fastuosa (proud). A synonym of *B. speciosa*.

B. glabra Sanderiana (Sander's). A very floriferous variety. 1895.

B. refulgens (shining). *fl.*, bracts brilliant purple-mauve, produced in long, pendulous racemes. *l.* dark green, pubescent. Brazil, 1887. Stove.

FIG. 179. BOUGAINVILLÆA SPECTABILIS.

Bougainvillæa—*continued.*

B. speciosa splendens (splendid). A distinct variety, having deep purplish-mauve bracts. 1895.

B. s. variegata (variegated). A garden variety with variegated foliage. 1890.

B. spectabilis lateritia (brick-red). In this variety the bracts are of a brick-red. (I. H. 466.) The inflorescence of the typical plant is shown in Fig. 179.

BOUILLIE BORDELAISE. *See* **Bordeaux Mixture.**

BOUNCING BET. *See* **Saponaria officinalis.**

BOURBON ROSES. Hardy, free-flowering, vigorous Roses, descended from *Rosa indica Bourboniana.* Souvenir de la Malmaison is still one of the best varieties.

BOURRERIA (named in honour of Bourrer, a Nuremberg chemist). SYNS. *Beurreria, Crematomia.* ORD. *Boragineæ.* A genus embracing sixteen or eighteen species of stove trees or shrubs, natives of the West Indies, Mexico, Central America, &c., and closely allied to *Ehretia.* Flowers whitish, often larger than in *Ehretia.* Leaves alternate or rarely somewhat whorled. Two of the species have been introduced, but they are of no great horticultural value.

BOURSAULT ROSES. Vigorous climbing Roses, descended from *Rosa alpina.*

BOURSE. This word, of French origin, has been applied to some peculiar swellings frequently seen upon trees and shrubs, and due to physical changes. On fruit trees, such as Apples and Pears, they are often found, and may be said to consist of nutritive elements stored up for the development of the fruits, but which, owing to the wood in the vicinity being killed, do not reach the growing point.

BOUSSINGAULTIA. The ten species included in this genus are all natives of tropical America. Flowers small, hermaphrodite, on short or slender pedicels, disposed in axillary and terminal racemes. Leaves alternate, petiolate or almost sessile, ovate, elliptic or cordate, more or less fleshy, entire. To the species described on p. 206, Vol. I., the following should be added:

B. cordata (cordate). A succulent climber, nearly allied to *B. baselloides.* Peru, 1895.

BOUTELOUA (named in honour of Estéban Boutelou, 1776-1813, Professor of Agriculture at Madrid, and Cláudio Boutelou, 1774-1842, Director of the Botanic Garden at Madrid). SYNS. *Actinochloa, Eutriana.* Including *Atheropogon.* ORD. *Gramineæ.* A genus embracing about twenty-five species of annual or perennial Grasses, all American. Spikelets unilateral, one- or two-flowered; glumes two, acute, carinate; spikes usually numerous, at the side of the peduncle, rarely reduced to a single, terminal one. *B. racemosa* (SYN. *Atheropogon apludioides*) has been introduced, but is of no particular horticultural value.

BOUVARDIA. SYN. *Æginetia.* This genus comprises about twenty-six species of herbs and shrubs, mostly Mexican. These choice greenhouse flowers are being more sought after year by year, owing to their great value for late autumn and winter flowering, especially for the making up of small bouquets, buttonholes, and for table decoration. To the species, &c., described on p. 207, Vol. I., the following should be added:

B. longiflora flammea (flame-coloured). *fl.* large, with a rosy-pink tube and salmon-coloured lobes.

B. scabra (scabrous). *fl.* bright pink, ½in. in diameter, freely produced in dense, corymbose cymes; corolla tube ¾in. to 1in. long, the lobes elliptic-ovate, somewhat acute. January. *l.* in distant whorls of three or rarely four, ovate, acuminate, narrowed to a very short petiole; lower ones 2in. to 3in. long, 1in. to 1½in. broad, the upper ones gradually smaller. Stems terete, herbaceous, hairy, 1ft. to 1½ft. high.

Varieties. The following are valuable additions to the list of varieties described on p. 207, Vol. I:

BRIDAL WREATH, white; CANDIDISSIMA, pure white; ELEGANS, scarlet; FLAVA, light yellow; HOGARTH FLORE PLENO, scarlet, double; HUMBOLDTII CORYMBIFLORA, white; INTERMEDIA, salmon-pink; JASMINOIDES, white, free; MRS. ROBERT GREEN, rose-pink; PRESIDENT CLEVELAND, bright scarlet, with rose tube, free, excellent; PRIORY BEAUTY, light rose; PURITY, white, very fragrant and free; SANG. LORRAINE, vermilion, double; THE BRIDE, white, blush tinted; THOMAS MEEHAN, bright scarlet, with paler tube, double; TRIOMPHE DE NANCY, orange-red, double; VICTOR LEMOINE, bright scarlet, very double; VULCAN, bright scarlet.

Bouvardia—*continued.*

BOWIEA (of Haworth) is now included under **Aloe** (which *see*).

BOWSTRING HEMP. *See* **Sanseviera.**

BRABYLA. A synonym of **Brabeium** (which *see*).

BRACHELYTRA. *See* **Staphylinidæ.**

BRACHIATE. A term applied to branches which are decussate and spreading—*e.g.*, those of the Ash.

BRACHIONIDIUM (from *brachion, brachionos,* an arm, and *eidos,* like; the column bears two arm-like processes). ORD. *Orchideæ.* A small genus (three species) of stove, epiphytal Orchids, natives of Colombia or Bolivia; they are closely related to *Masdevallia,* but have stem-like rhizomes. Flowers mediocre or rather large; sepals very shortly connate, or spreading from the base, produced in a point or tail; petals similar, but rather smaller; lip small, sessile, undivided; peduncle one-flowered. Leaf solitary, coriaceous, rather small. Only one species has been introduced. For culture, *see* **Masdevallia.**

B. Sherringii (Sherring's). *fl.* solitary, borne on a peduncle 1in. to 1½in. long; sepals and petals seven to eight lines long, the lateral sepals connate and shortly bifid; lip very short, three-lobed. *l.* ¾in. to 1½in. long, elliptic-lanceolate or ovate-oblong. Primary stems climbing and rooting; secondary ones short, one-leaved. West Indies, 1893.

BRACHYACHIRIS. A synonym of **Gutierrezia** (which *see*).

BRACHYCARPÆA (from *brachys,* short, and *karpos,* fruit). ORD. *Cruciferæ.* A small genus (two species) of greenhouse, sub-shrubby perennials, natives of South Africa. Flowers yellow or purple, large, in long, leafless racemes. Leaves oblong or linear, entire. *B. varians purpurascens* (SYN. *Polygala bracteolata*) has been introduced, but is probably not now in cultivation.

BRACHYCHEILA. A synonym of **Euclea** (which *see*).

BRACHYCHILUM (from *brachys,* short, and *cheilos,* a lip; in allusion to the suppressed labellum). ORD. *Scitaminеæ.* A monotypic genus. The species is a stove, herbaceous plant, allied to **Hedychium** (which *see* for culture).

B. Horsfieldii (Horsfield's). *fl.* yellow, few, in a terminal spike; corolla tube slender, the lobes linear, above ½in. long; lateral staminodia two, white or yellow, oblong, less than 1in. long; stamen as long as the corolla-tube. May. *l.* eight or nine, alternate, sessile, oblong-lanceolate, glabrous, less than 1ft. long. Stem stiffly erect, 2ft. long. Java, 1894.

BRACHYCHITON. Now included under **Sterculia** (which *see*), the specific names given on p. 208, Vol. I., remaining unchanged. *B. populneum* is a synonym of *S. diversifolia.*

BRACHYCOME. Including *Brachystephium.* Forty species are included in this genus: three are natives of New Zealand, one is tropical African, and the rest are Australian. To that described on p. 208, Vol. I., the following should be added:

B. diversifolia (variable-leaved). *fl.-heads* white, larger than in any other species; involucre about ½in. across; ray florets long and numerous. May. *l.,* lower ones often crowded, spathulate or oblong, coarsely toothed or pinnatifid; upper ones smaller and less divided. Stem usually simple, 1ft. to 2ft. high, rarely reduced to a short scape. Australia, 1824. A tufted, greenhouse perennial. SYNS. *Brachystephium leucanthemoides, Pyrethrum diversifolium* (B. R. 1025; H. E. F. iii. 215).

BRACHYGLOTTIS (from *brachys,* short, and *glossa,* a tongue; in allusion to the short ligulate corollas of the ray flowers). ORD. *Compositæ.* A monotypic genus. The species

Brachyglottis—*continued.*

is a noble, half-hardy tree or low shrub. It succeeds well in a compost of peat and loam in equal proportions, providing, of course, for drainage. It may be grown in pots for the conservatory. It is usual to pinch out the points of the growths frequently in order to secure bushy plants.

B. repanda (repand-leaved). *fl.-heads* minute, excessively numerous, tomentose. *l.* very large (6in. to 12in. long), alternate, petiolate, broadly ovate-oblong or cordate-oblong, irregularly lobed or waved on the margin, dark shining green above, densely soft, white, cottony-tomentose beneath. Branches slender, flexuous. New Zealand, 1895. This will probably prove a good seaside tree in favoured districts.

BRACHYLÆNA. SYN. *Oligocarpha.* Half-a-dozen species are included in this genus. Flower-heads dicœcious, discoid, in small racemes or panicles. Leaves alternate entire.

BRACHYLOMA (from *brachys*, short, and *loma*, a fringe; in allusion to the fimbriate scales or bunches of hair in the throat of the corolla). ORD. *Epacrideæ*. A genus embracing half-a-dozen species of greenhouse shrubs, of varying habit, all Australian. Flowers small, axillary, solitary, shortly pedicellate. Leaves striate-nerved. Two of the species, *B. ciliatum* (SYN. *Lissanthe ciliata*) and *B. daphnoides* (SYN. *L. daphnoides*, L. B. C. 466), have been introduced, but are probably no longer cultivated.

BRACHYLOMA (of Hanstein). Included under **Isoloma** (which *see*).

BRACHYOTUM. SYN. *Arthrostemma* (in part). This genus embraces about two dozen species of rigid, stove or greenhouse shrubs, natives of Peru, Bolivia, and Colombia. Flowers yellow or purple, rather large, drooping or nodding, one to three towards the tips of the branchlets; calyx lobes and petals four or five each; stamens eight or ten. Leaves usually ovate or oblong, with recurved margins.

BRACHYPTERIS (from *brachys*, short, and *pteron*, a wing; in allusion to the short wings borne by the fruits of this genus). ORD. *Malpighiaceæ*. A genus consisting of a couple of species of stove, twining shrubs, natives of tropical America and the West Indies. Flowers yellow, simply umbellate or corymbose; calyx five-parted; petals clawed, unequal. Leaves opposite, entire, petiolate. Only one species—*B. borealis*—has been introduced, and it is doubtful if that is now in cultivation.

BRACHYRHYNCHOS. Included under **Senecio** (which *see*), the correct name of *B. albicaulis* being *S. diversifolius pinnatifidus.*

BRACHYRIS. A synonym of **Gutierrezia** (which *see*).

BRACHYSCYPHA. Included under **Lachenalia** (which *see*). *B. undulata* is synonymous with *L. pusilla.*

BRACHYSEMA. About fourteen species, confined to tropical and Western Australia, are referred to this genus. To those described on pp. 208-9, Vol. I., the following should be added:

B. aphyllum (leafless). *fl.* red, pedicellate and solitary in the upper notches; calyx ⅜in. long; standard ovate, scarcely half as long as the calyx. Stems erect or diffuse, flat, with rigid, broad wings descending from the nodes, truncate and forming an obtuse notch at the upper end. 1849. (B. M. 4481.)

B. acuminatum is rare in cultivation.

BRACHYSPATHA. Bentham and Hooker include this under **Amorphophallus** (which *see*).

BRACHYSTELMA. About fourteen species, natives of South and Eastern tropical Africa, are included in this genus. To those described on p. 209, Vol. I., the following should be added:

B. caffrum (Kaffir). *fl.* bright clear yellow, lateral between the bases of the leaves, solitary or rarely two from the same node; corolla rotate. July. *l.* ovate, acute, ⅛in. to ⅜in. long. Stems slender, scaberulous, 3in. to 5in. long. S. Africa, 1894.

B. caudatum (tailed). A synonym of *B. crispum.*

B. crispum (crisped). *fl.* greenish, with dark spots; corolla segments long-attenuated. September. *l.* oblong, obtuse, sinuated, irregularly undulated-crisped, attenuated into the petioles. *h.* 6in. South Africa, 1829. (B. M. 3016.) SYN. *B. caudatum.*

BRACHYSTEPHIUM. Included under **Brachycome** (which *see*). *Brachystephium leucanthemoides* is synonymous with *Brachycome diversifolia.*

BRACTEOSE. Having large or numerous bracts.

BRADLEIA. Included under **Phyllanthus** (which *see*).

BRAHEA. Of the four known species of this genus, one is indigenous to Mexican Texas and the mountains of Mexico, and the rest inhabit Mexico and the Andes. To that described on p. 209, Vol. I., the following should be added:

B. edulis (edible). A synonym of *Erythea edulis.*

B. filamentosa (thread-like). A synonym of *Washingtonia filifera.*

B. glauca (greyish-green). A garden synonym of *Erythea armata.*

B. nitida (shining). *fl.*, spadix very large, much branched, glabrous. *fr.* black, about the size of a pea. *l.* large, fan-like, palmately cleft, glaucous-green. Mexico, 1887. (R. H. 1887, p. 344, f. 67-70.)

B. Roëzlii (Roëzl's). A synonym of *Erythea armata.*

BRAINEA. The roots of *Brainea insignis* are of a remarkably brittle nature, and great care must be taken in repotting; if that operation is carelessly done, a certain quantity of roots are mutilated, and the chances are that the plant will never recover. The compost which it prefers is a mixture of fibrous peat and loam in equal parts, with the addition of some sharp sand; it also requires thoroughly good drainage, as it should receive plenty of water at the roots and on the stem. It is usually propagated from spores, which germinate freely.

BRAKE FERN. *See* **Pteris aquilina.**

BRAKE-ROOT. *See* **Polypodium vulgare.**

BRAMIA. A synonym of **Herpestis** (which *see*).

BRANCHING ANNUAL STOCK. A common name for **Malcolmia maritima** (which *see*).

BRAND. This is another popular name for the *Ustilagineæ*, or Smut Fungi.

BRANDED PINE WEEVIL. A popular name for *Pissodes notatus*, described and illustrated under **Pine Weevils** (Vol. III.).

BRANDTIA. A synonym of **Arundinella** (which *see*).

BRASENIA SCHREBERI. The correct name of the plant described on p. 164, Vol. II., as *Hydropeltis purpurea. Brasenia* is a monotypic genus.

BRASSAIOPSIS (from *Brassaia*, an allied genus, not known in our gardens, and *opsis*, resemblance). ORD. *Araliaceæ*. A genus comprising about eight species of prickly or unarmed, glabrous or tomentose, stove, evergreen trees or shrubs, natives of the East Indies and the Indian Archipelago. Flowers usually polygamous; calyx five-toothed on the margin; petals five, valvate; stamens five; pedicels continuous with the flowers; umbels in large, compound panicles. Leaves digitate or palmate. Only one species calls for mention here. It requires similar culture to the stove species of **Aralia** (which *see*).

B. speciosa (showy). *fl.* yellow; panicle usually 1ft. or more in length; bracts at the base of the branches persistent. April. *l.* digitate; leaflets lanceolate or elliptic, 4in. to 8in. long, 1in. to 3in. broad, rounded or attenuated at base, entire, crenulate or lightly sub-serrate; petiolules usually more than 1in. long. India, 1847. SYN. *Hedera glomerulata* (B. M. 4804; R. G. 1863, t. 411).

BRASSAVOLA. About a score species, ranging from Mexico and the West Indies to Brazil, are included in this genus. Several formerly classed here (including

Brassavola—*continued.*

B. Digbyana and *B. glauca*) are now referred to *Lælia*, under the same specific names. The plants require similar treatment to that recommended for **Cattleya.**

B. elegans (elegant). A synonym of *Tetramicra rigida.*

BRASSIA. This genus embraces about a score species. To those described on pp. 209-10, Vol. I., the following should be added :

B. bicolor (two-coloured). *fl.* yellow and brown; sepals 2½in. long, acuminate; petals 1½in. long; lip lanceolate-oblong, 1⅝in. long, the margin slightly undulated; scape erect, many-flowered. *l.* linear-oblong. Pseudo-bulbs oblong or ovoid-oblong, somewhat compressed. Peru. (L., t 378.)

B. brachiata (branched). *fl.* very large, seven to ten in a raceme; sepals light yellowish-green, spotted near the base, 6in. long; petals 4in. long, with more spots at base; lip light yellow, the basal half with revolute margins; crest white, spotted with orange. *l.* linear-lanceolate, 9in. to 12in. long. Pseudo-bulbs 3in. to 5in. long. Guatemala, 1843. (B. R. 1847, t. 29.)

B. caudata hieroglyphica (hieroglyphic). In this variety the spots are more prominent and of hieroglyphic appearance. (L., t. 76.)

B. cinnamomea (cinnamon). A synonym of *B. Keiliana.*

B. elegantula (rather elegant). *fl.* small; sepals green, with brown bars, spreading; lip white, with two keels, hairy inside, dotted purplish-brown in front of the calli; raceme two- to five-flowered. *l.* and pseudo-bulbs glaucous. Mexico, 1885. An elegant species.

B. guttata (striped). A form of *B. maculata.*

B. Keiliana (Keil's). *fl.* disposed in a loose, many-flowered raceme; sepals and petals at first yellow, eventually turning brownish-orange; lip whitish; bracts boat-shaped, longer than the ovaries. Colombia. A dwarf and compact species; it will thrive in the Cattleya house. (R. G. 1862, t. 365; R. X. O., t. 45, three forms.) SYNS. *B. cinnamomea* and *Oncidium Keilianum.*

B. K. tristis (sad). *fl.* spider-like, borne in long spikes; sepals and petals deep sepia-brown; lip lemon-yellow, with a semi-circular series of brown spots at the base, the apical tail longer and springing more abruptly from the light yellow blade. 1895. A curious variety. (R. X. O., t. 45, f. 3; W. O. A. 347.)

B. Lewisii (Lewis's). *fl.* ten to twelve in a raceme; sepals and petals greenish-yellow, spotted with brown; lip pale yellow, with white keels and orange marks; raceme about 9in. long. *l.* linear-oblong, 6in. long. Pseudo-bulbs oblong. Habitat not recorded. 1893.

B. maculata major (larger). *fl.* freely produced; sepals and petals greenish-yellow, spotted brown; lip white, spotted dark brown. Jamaica.

B. signata (marked). *fl.* small, seven to ten to a scape; sepals and petals bright green, spotted with brown in the basal half, the former 2in. long, the latter smaller; lip white, oval, shell-like, with two brown-purple spots and a yellow one. *l.* broadly strap-shaped, 9in. to 12in. long. Pseudo-bulbs 3in. to 5in. long, two-leaved. Origin unknown. 1881.

BRASSICA. This important genus embraces about eighty species (as many as 150 have been described as such), broadly dispersed, but not indigenous in either Australia or America. Nine species are natives of Britain. *Sinapis*, which is included here by Bentham and Hooker, is kept separate in this work. Some of the Kales are used for ornamental purposes, and will grow in almost any soil.

B. oleracea crispa (curled). *l.* arching, elegantly cut into curled divisions. *h.* 4ft. An ornamental variety, seen to perfection in autumn and winter.

B. o. fimbriata (fringed). *See* **Borecole.**

B. o. palmifolia (palmate-leaved). *l.* produced near the summit of the stem, and having an almost Palm-like appearance. *h.* 6ft. An ornamental form, producing a fine effect in summer and autumn.

BRASSO-CATTLEYA. The name given to a supposed natural hybrid between *Brassavola tuberculata* and *Cattleya intermedia.*

BRASSO-CATT-LÆLIA. *Lindleyano-elegans* is the name given to a hybrid (*Brasso-Cattleya Lindleyana* and *Lælio-Cattleya elegans*) raised by Lawrence.

BRAUNEA (in part). A synonym of **Tiliacora** (which *see*).

BRAVOA. SYN. *Cætocapnia.* According to J. G. Baker, there are four species, natives of Mexico. Flowers red or whitish, usually twin; perianth persistent, the tube

Bravoa—*continued.*

long and almost cylindrical, the lobes short, ovate, subequal; racemes long. Radical leaves few, lanceolate or linear; cauline ones much smaller. To the information given on p. 211, Vol. I., the following should be added :

B. Bulliana (Bull's). A synonym of *Prochynanthes Bulliana.*

BRAWLINS. *See* **Vaccinium Vitis-Idæa.**

BRAYA (named after Count Bray, a German botanist). Including *Platypetalum.* ORD. *Cruciferæ.* A genus embracing about a dozen species of tufted, hardy perennials, natives of Europe, Asia, Africa, and tropical mountainous regions. Flowers white, pink, or purple; sepals short; stamens free; raceme short or elongated, sometimes corymbose, often leafy at base; scape usually naked, sometimes one-flowered. Leaves radical, spathulate or linear, entire or toothed. *B. alpina* (SYN. *B. purpurascens*) has been introduced, but it is of little horticultural value.

BRAZORIA (the original species was discovered on the Rio Brazas, in Texas). ORD. *Labiatæ.* A small genus (three species) of hardy annuals, natives of North America. Flowers rose-purple, disposed in twiggy racemes or spikes; calyx bilabiate, the upper lip two-lobed, the lower three-lobed; corolla with an inflated throat and a more or less exserted tube. Leaves oblong, mostly sessile, denticulate, the lowest tapering into a petiole; floral ones reduced to small bracts. Only one species calls for mention. It thrives under ordinary treatment in rich soil.

B. scutellarioides (Scutellaria-like). *fl.*, corolla ½in. long, its lobes entire or merely retuse; spikes or racemes loose, mostly panicled. Summer. *l.* as above described. *h.* 1½ft. Texas. 1834. SYN. *Physostegia truncata* (B. M. 3494).

BREAK. This term has several horticultural meanings: To put forth new leaves or buds; to "bolt" or run to seed prematurely; to depart from the typical form, producing a new variety. It is also applicable to Vines when they start into growth. If the buds all shoot regularly, the whole length of the rod, or cane, is termed a "good Break." On the other hand, if the buds fail to start in places, and blank spaces are left on the rods, it is considered a "bad Break." Bulbs are said to Break when they send forth growths and roots. Sometimes when a plant produces a sport distinct in character it is said to be a Break. The first Break in Chrysanthemums is usually about the middle of May, a little earlier or later, according to the time of rooting the cuttings.

BREAKSTONE. *See* **Saxifraga.**

BREAST-WOOD. On espalier and all trees trained against walls the wood that grows out in front of the trees is termed Breast-wood. If bent in it would form unsightly branches. It is much the better plan to cut all such Breast-wood into about three eyes at the end of July, and then in winter cut back to a couple of eyes, entirely removing some if very numerous.

BREHMIA. A synonym of **Strychnos** (which *see*).

BREMONTIERA (named in honour of M. Bremontier). ORD. *Leguminosæ.* A monotypic genus. The species, *B. Ammoxylon*, is a stove, evergreen shrub, native of Mauritius; it was introduced in 1826, but is probably no longer grown.

BREVOORTIA (a commemorative name). ORD. *Liliaceæ.* A monotypic genus. The species, *B. Ida-maia*, is the plant described on p. 213, Vol. I., under its old name, *Brodiæa coccinea.*

BREXIA. SYN. *Venana.* One or two species, confined to Madagascar, are referred to this genus.

BREYNIA (named in honour of Johann Philipp Breyn, a German botanist). SYN. *Melanthesa.* ORD. *Euphorbiaceæ.* A genus embracing about a dozen species of stove or greenhouse shrubs or small trees, natives of tropical Asia, Australia, and the South Pacific Islands. Flowers monœcious, apetalous, small, axillary, pedicellate, solitary in the axils or the males fascicled. Berry globose

Breynia—*continued.*

or depressed. Leaves alternate, petiolate, often distichous and drying blackish. Only one species is known to cultivation. For culture, *see* **Phyllanthus.**

B. turbinata (turbinate). *fl.* green, those of both sexes borne on the same raceme. July. *l.* coriaceous, 1½in. long, ¾in. to 1in. broad, rhomboid-ovate, acute, glaucous and minutely foveolate-dotted beneath. *h.* 2ft. China. SYN. *Phyllanthus turbinatus* (B. M. 1862; L. B. C. 731).

BRICKELLIA (commemorative name). Including *Bulbostyles* in part. ORD. *Compositæ.* A genus embracing about forty species of stove or greenhouse herbs or under-shrubs, all American. Flower-heads white or pink, homogamous, paniculate. Leaves opposite or alternate, toothed or entire, rarely cut. One or two of the species have been introduced, but the following is the only one calling for mention. For culture, *see* **Eupatorium.**

B. grandiflora (large-flowered). *fl.-heads* reddish, disposed in large, terminal corymbs. *l.* rugose, cordate, acute, serrated. Stem paniculate at summit. North America, 1883. An ornamental, hardy perennial. SYN. *Eupatorium grandiflorum* (R. H. 1882, p. 384).

BRIDGESIA. A synonym of **Ercilla** (which *see*).

BRIGNOLIA. A synonym of **Isertia** (which *see*).

BRILLANTAISIA. SYNS. *Belantheria, Leucorhaphis.* About seven or eight species, natives of tropical Asia and Madagascar, are included in this genus.

BRINDLED BEAUTY MOTH (*Biston hirtarius*). Frequently this Moth causes the gardener and the forester no little anxiety on account of its ravages upon Plums, Pears, Oaks, Elms, Limes, &c. Even in London its presence is very familiar. The Moth is on the wing during April and May, and though not conspicuous as to markings, it measures about 2in. in wing-expanse. The fore-wings are greyish-brown, sprinkled with a darker colour, and like the lighter hind-wings irregularly banded with black, though these latter markings are not as distinct in the hind-wings as in the fore-wings (see Fig. 180). The male has beautifully fringed antennæ, as shown in the illustration; whereas in the female these organs are filiform. The eggs are deposited in rings upon the food-plant selected, and therefore are fairly conspicuous. They should always be destroyed.

FIG. 180. BRINDLED BEAUTY MOTH.

FIG. 181. CATERPILLAR OF BRINDLED BEAUTY MOTH.

From June to July the caterpillars (see Fig. 181) may be found; they are voracious feeders, and the foliage suffers considerably. They are of a variable brown colour, with bright yellow dots upon each segment. When full-fed, the pupal state is assumed beneath the soil, the perfect insect emerging in the spring of the following year.

Besides the preventive measures already suggested in connection with the destruction of the eggs, the caterpillars may be destroyed by poisoning their food-plant with Paris Green (1oz. to 20gall. of water).

BRINDONIA. A synonym of **Garcinia** (which *see*).

BRINING. A method employed to hasten the germination of those seeds having hard shells. It consists in steeping them in warm water for twenty-four hours before sowing, and is especially advisable with such seeds as those of Cannas and Palms.

BRISTLE FERN. *See* **Trichomanes.**

BRIZA. The ten species of this genus inhabit Europe, North Africa, temperate Asia, and South America. Leaves flat or narrowly convolute, sometimes bristly. To the species described on pp. 211-2, Vol. I., the following should be added:

B. rotundata (round). *fl.* disposed in narrow panicles; spikelets erect. *l.* erect, narrow. Mexico, Brazil, and Chili, 1887. An ornamental, annual Grass. (R. G. 1887, p. 638.)

BROAD BEAN RUST (*Uromyces fabæ*). The name above adopted would suggest that the Broad Bean alone was attacked by this Rust, but this is not the case. Peas and several wild plants are similarly affected. Usually the disease is not noted until the brown spots on the foliage (uredospore stage) have made their appearance. Prior to this, however, there has been a Cluster-cup (æcidium) stage. Plants which have reached the uredospore (summer spore) stage quickly spread the disease, unless spraying with a fungicide (liver of sulphur) is adopted. Finally, teleutospores are formed, and these carry the fungus over the winter to repeat the mischief in the following spring. All old haulms should be burned and not buried, as is frequently case in cottage and allotment gardens.

BROAD-BORDERED YELLOW UNDER-WING. *See* **Tryphæna.**

BROCCHIA (of Mauri). A synonym of **Simmondsia** (which *see*).

BROCCHINIA (named after Giovanni Battista Brocchi, an Italian naturalist). ORD. *Bromeliaceæ.* A small and very distinct genus (three species) of stove plants with a woody, Yucca-like trunk, natives of Brazil and Guiana. Flowers whitish, small, in a loose, decompound panicle; perianth inserted above the middle of the ovary; sepals obovate-oblong, as long as the orbicular, short-clawed petals; stamens a little shorter than the sepals and petals; ovary three-celled. Leaves densely rosulate, with a large, entire, lorate blade. Only one species has yet been introduced. It requires culture similar to **Billbergia** (which *see*).

B. Andreana (André's). A synonym of *B. cordylinoides.*

B. cordylinoides (Cordyline-like). *fl.* yellowish-white, less than ¼in. long; panicle 6ft. to 8ft. long; peduncle shorter than the leaves. Autumn. *l.* 3ft. to 4ft. long, 6in. to 7in. broad, deltoid at apex. Trunk 12ft. to 15ft. high, 6in. to 8in. in diameter. British Guiana, 1882. SYNS. *B. Andreana* and *R. demerarensis* (of gardens), *Cordyline macrantha* (G. C. 1880, ii. 243, f. 47).

B. demerarensis (Demerara). A synonym of *B. cordylinoides.*

BROCCOLI. Two new varieties that deserve mention are Walcheren and Early Purple Sprouting. These, with the other early varieties named—Veitch's Self-protecting Autumn Purple Cape and Snow's Winter White—will afford a supply until Christmas, or later. Then should follow, in the order named, Improved Sprouting, Osborne's Winter White, Early White, Perfection, Leamington, April Queen, Latest of All, Model, and Late Queen. These would continue the supply until June, when Cauliflowers are ready.

BRODIÆA. Bentham and Hooker include here *Calliprora, Hesperoscordon,* and *Triteleia,* the genus as thus constituted comprising about thirty species, all extra-tropical American. To those described on p. 213, Vol. I., the following should be added. *See also* **Calliprora** and **Triteleia.**

Brodiæa—*continued.*

B. californica (Californian). This is closely related to *B. grandiflora*, but has flowers varying from rose-colour to deep purple, 1½in. to 2in. long, twenty-five in an umbel, and borne on a longer scape. Sacramento Valley. The best of all the species.

B. capitata pauciflora (few-flowered). *fl.* fewer and pedicels longer than in the type. 1896. There is also a white variety, *alba* (G. C. 1896, xx., p. 238, f. 44).

B. coccinea. The correct name is *Brevoortia Ida-maia.*

B. Douglasii (Douglas'). *fl.* violet-blue, inodorous, ten to twenty in a dense umbel; perianth funnel-shaped, 1in. long, the segments oblong, acute; scape slender, 1ft. to 1½ft. long. May. *l.* generally two, light green, flaccid, deeply channelled, shorter than the scape. Bulb small, globose. California, &c., 1876. (B. M. 6907.)

B. grandiflora Warei (Ware's). *fl.* lilac-rose, 3in. long; scape 2ft. to 2½ft. high. California, 1886. A beautiful variety.

B. Howellii lilacina (lilac-coloured). A charming little hardy plant, producing umbels of deep bluish-lilac flowers, not unlike an Agapanthus in shape. 1894. (Gn., 1894, xlvi., p. 502, pl. 992.)

B. hyacinthina lactea (hyacinth-blue, milky). The correct name of *B. lactea.* (G. C. 1896, xx., p. 459, f. 80).

B. ixioides erecta (erect). *fl.* bright yellow, about thirty in a spreading umbel. 1896. A dwarf form.

B. minor (lesser). *fl.* two to six in an umbel; perianth 1in. or less in length, with a more spreading limb; scape slender, 3in. to 6in. long. Otherwise like *B. grandiflora.* Southern California.

B. Orcuttii (Orcutt's). *fl.* bright lilac, less than 1in. long, with a very short tube, five to fifteen in an umbel; filaments longer than the anthers; peduncle stout, 1ft. or more in length. *l.* linear, flat, conduplicate. San Diego, 1896. (G. C. 1896, xx., p. 215, f. 40.)

B. Palmeri (Palmer's). *fl.* bright lilac, ½in. long, shortly stalked, many in an umbel; segments oblong, as long as the obconic tube. *l.* numerous, firm, very thin, linear. *h.* 1ft. to 2ft. California, 1889. This plant produces a large number of small bulbils on the surface of the ground. (G. & F. 1889, p. 245, f. 107.)

B. rosea (rosy). *fl.* rose-red, less than 1in. long, five to eight in an umbel; free portion of fertile filaments dilated; staminodia white; peduncle 3in. to 6in. long. *l.* sub-terete. Lake County, 1896. (G. C. 1896, xx., p. 213, f. 39.)

B. volubilis. The correct name is *Stropholirion californicum.*

BROMELIA. SYN. *Agallostachys.* As this genus at present stands, according to J. G. Baker, it embraces only half-a-dozen species, a large number of plants formerly placed under *Bromelia* being now classed under those genera named on p. 213, Vol. I., and under *Distiacanthus* and *Rhodostachys.* Inflorescence a dense panicle, the lower branch-bracts with a serrated cusp, and the crowded, arcuate stem-leaves similar to the rosette-leaves in texture, but shorter and often bright red. Fruit a large, yellowish berry.

B. amazonica (Amazon). A synonym of *Disteganthus scarlatinus* and *Karatas amazonica.*

B. antiacantha is a synonym of *B. fastuosa.*

B. bicolor is a synonym of *Rhodostachys bicolor.*

B. Binoti (Binot's). A garden form of *B. Pinguin.*

B. carnea (fleshy). A synonym of *Rhodostachys andina.*

B. fastuosa (proud). *fl.* reddish-violet; panicle 1ft. to 2ft. long, stiffly erect, the branch-bracts pale, with spine-edged cusps; peduncle 1ft. long, its leaves 1ft. to 1½ft. long, often bright red. August. *l.* 100 or more in a rosette, 4ft. to 5ft. long, 1½in. to 2in. broad, with copious hooked, pungent, yellowish prickles. Central and South Brazil, 1815. Plant stemless. (L. C. B. 1; R. G. 493.) SYNS. *B. antiacantha, Karatas antiacantha.*

B. Joinvillei is a synonym of *Rhodostachys bicolor.*

B. laciniosa (torn). *fl.* in a very dense panicle 2in. to 3in. in diameter; petals dull lilac, faintly tomentose at tip; peduncle 1ft. long, its leaves bright red. *l.* rigid, ensiform, sub-erect in the lower half, 4ft. to 5ft. long, 1½in. broad, with large, hooked prickles. North Brazil, 1873. Plant stemless. SYN. *Karatas guianensis.*

B. paraguayensis (Paraguay). A garden form of *B. Pinguin*

B. Pinguin (native name). *fl.* in a dense, stiffly erect panicle 1ft. to 2ft. long, with densely mealy branches; petals reddish, densely white-tomentose at tip; peduncle erect, 1ft. long. March. *l.* 100 or more in a rosette, erect in the lower half, 5ft. to 6ft. long, 1½in. to 2in. broad, with very large, toothed, brown prickles. Tropical America, 1690. Plant stemless. *B. Binoti* and *B. paraguayensis* are garden varieties with bright red inner leaves.

B. undulata (wavy). A synonym of *Ananas macrodontes.*

B. zebrina (zebra-streaked). A synonym of *Billbergia zebrina.*

BROMHEADIA (named in honour of Sir E. F. Bromhead, Bart). ORD. *Orchideæ.* A small genus (about four species) of rigid, terrestrial or epiphytal, stove Orchids, extending from Siam and Birma to Singapore and the Malayan and Philippine Islands. Flowers usually showy, white or orange; sepals lanceolate, acute, keeled; petals rather shorter and broader than the sepals; lip three-lobed, the lateral lobes erect, the middle one longer; column curved, elongated; pollen masses two; racemes one- to three- or many-flowered, flexuous, elongated, rarely short and congested. Leaves distichous, rigid, usually lanceolate, obtuse, bilobed at apex, rarely ensiform, re curved, pointed. Stems not bulbous, compressed. *B. palustris*, which is probably the only species known in gardens, thrives in a compost of fibry peat and sand. It may be increased by means of offsets or by division after the flowering period. The name *palustris* is, according to Mr. H. N. Ridley ("Journal of the Linnean Society," vol. xxviii., p. 331), most inapt, as the plant prefers hot, sunny places as its habitat.

B. palustris (marsh-loving). *fl.* large, sweetly scented, opening in the early morning and very soon closing; sepals pure white or tinged with pink, 1½in. long; petals pure white; lip white, veined with violet-pink; raceme flexuous, about 3in. long. June. *l.* spreading, rather distant below, and gradually passing into sheaths at the top of the otherwise bare stem. *h.* 1ft. to 6ft. Cochin China, &c., 1840. (B. M. 4001.)

BRONGNIARTIA. Including *Peraltea.* The eight species forming this genus are distributed over Chili, Bolivia, and Central America.

BROOK-WEED. *See* **Samolus.**

BROOM, ROCK. *See* **Genista.**

BROOM, RUSH. *See* **Spartium junceum** and **Viminaria.**

BROSIMUM. Cow-tree. With this genus Bentham and Hooker regard *Galactodendron* (see p. 39, Vol. II.) and *Piratinera* as synonymous. It includes about eight species, natives of tropical America.

B. Galactodendron. The correct name of *Galactodendron utile.*

BROTERA (of Willdenow). A synonym of **Cardopatium** (which *see*).

BROTERA (of Cavanilles). A synonym of **Melhania** (which *see*).

BROTERA (of Sprengel). A synonym of **Hyptis** (which *see*).

BROWALLIA. ORD. *Solanaceæ.* Tropical America is the home of the half-dozen species included in this genus. To those described on p. 214, Vol. I., the following should be added:

B. Czerwiakowski (Czerwiakowski's). A synonym of *B. viscosa.*

B. elata is synonymous with *B. demissa.*

B. pulchella (pretty). A garden synonym of *B. viscosa.*

B. speciosa (showy). *fl.* solitary, thrice the size of those of *B. grandiflora*; corolla hypocrateriform, the tube thrice the length of the calyx, the limb pale lilac beneath, dark purple above, striated. September. *l.* opposite or alternate, ovate, acuminate. Stem erect. *h.* 2ft. Tolima and Quindiu, 1846. (B. M. 4339.) The variety *major* has larger flowers than the type. 1894.

B. viscosa (clammy). *fl.*, calyx segments lanceolate, acute; corolla with violaceous, obovate, emarginate segments, the largest spotted white at base, the tube whitish, inflated at top; peduncles crowded at the tops of the branches. Summer. *l.* roundish-ovate, obtuse, hairy, 1in. to 1½in. long. *h.* 1ft. to 2ft. Colombia. Half-hardy annual. (R. G. 142.) SYNS. *B. Czerwiakowski, B. pulchella* (of gardens).

BROWN CLOVER. *See* **Trifolium spadiceum.**

BROWNEA. About eight species, all tropical American, are included in this genus. To those described on p. 215, Vol. I., the following should be added:

B. Crawfordii (W. H. Crawford's). *fl.* rich rosy-red, 3in. long, 1in. across, disposed in clusters of as many as seventy. *l.* about 2ft. long; leaflets six to ten pairs, the largest 1ft. long and 3in. broad. *h.* 15ft. 1891. A hybrid between *B. grandiceps* and *B. macrophylla.*

B. erecta (erect). A synonym of *Talisia princeps.*

B. princeps (of gardens). A synonym of *Talisia princeps.*

BROWNING, or BRUNISSURE. Although this troublesome disease is usually associated with Vines, yet it is by no means confined thereto, Apples, Pears, Cherries, Apricots, Melons, Cucumbers, Aucubas, and several others being liable to its attacks. The disease is one which frequently troubles the gardener, and even the plant-pathologist is not altogether certain as to its origin. By many it is ascribed to the presence of one of the so-called Slime fungi, which Viala and Sauvageau have named *Plasmodiophora vitis*, thus making it a near relative of the pest causing Club Root in Cabbages and other *Cruciferæ*. Others favour the idea that the disease is due rather to errors in cultivation. One thing, however, is certain, that the presence of green manure, badly-drained quarters, and wet and sunless weather, are predisposing causes.

The symptoms, as the common names above adopted suggest, are a Browning of the foliage, or it may be of the parts adjacent thereto. The spots are pale at first, and small, but rapidly extend, and change to a brown or reddish-brown, and not infrequently prematurely fall.

Where cultural errors like those noted above exist, they should be remedied; while the employment of a fungicide, such as sulphide of potassium (½oz. to 1gall. of water), should also be tried.

BROWNLEEA (named in honour of Rev. J. Brownlee, a missionary stationed in King William's Town, Caffraria, who discovered two of the species). ORD. *Orchideæ*. A small genus (three species) of greenhouse, terrestrial Orchids, natives of South Africa. They are closely allied to **Disa** (which *see* for culture), but have a very small, upturned lip, and an erect, concave or helmet-shaped odd sepal without a spur. Only one species is known to cultivation.

B. cærulea (blue). *fl.* pale blue, with violet dots and a long, straight spur; spike erect, lax, many-flowered. *l.* two or three, sessile or shortly petiolate, ovate or lanceolate, acuminate, three-ribbed. Stem erect, annual, springing from an amorphous, lobed tuber. 1893. (B. M. 7309.)

BROWNLOWIA. Three species of stove trees, natives of tropical America, are included in this genus. Flowers yellow, mediocre or rather small; calyx campanulate, irregularly three- to five-cleft; petals five, narrowed at base; stamens indefinite. Leaves entire, three- to five-nerved at base and penniveined.

BROWN ROT OF FRUIT (*Monilia fructigena*). Many kinds of fruits, both hard and soft, from the Apple and Pear to the Strawberry and Cherry, are liable to attacks from this mould, and in the case of Strawberries it is very difficult to deal with. The fungus attacks all parts of the plant from leaves to fruits, though the condition is more familiar to the gardener in the case of the latter, in which the first symptoms are the brownish-red patches, followed later by the greyish tufts, consisting of chains of spores arranged somewhat concentrically, waiting to be disseminated. The fruits attacked eventually have a dried-up appearance, and the small branches die away. The disease is tided over the winter by means of the hard bodies known as **Sclerotia** (which *see*). These form in the dried up fruits and, with the bursting of the new leaves, the tree is again attacked by the spores of the fungus released.

All shrivelled fruits should be removed and burned, and the foliage and twigs should be similarly treated. Care should also be taken that all fallen foliage and fruits are collected and burnt. Early in the New Year trees like Apples, Pears, Plums, and Cherries should be well sprayed with copper sulphate, ¾lb.; water, 15gall. This must never be applied to trees with expanded buds. It is a winter dressing only. Sulphide of potassium (1oz. to 3gall. of water) should also be tried at intervals when the leaves in the young state show the greenish-brown mould. In

Brown Rot of Fruit—*continued.*

the case of Strawberries more drastic measures have to be taken. The plants, after the crop has been gathered, should be cut down and the whole burned; while the next season, weak Bordeaux Mixture or sulphide of potassium should be thoroughly sprayed on before they blossom.

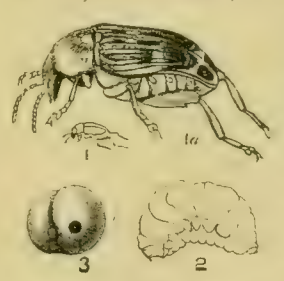
BROWN-TAIL MOTH. At times this Moth, which is illustrated and briefly described in Vol. II., under **Liparis**, proves very destructive to orchard trees, and also to other trees in park and garden. The insects are very prolific, and from two hundred to three hundred eggs are laid by an individual. The eggs themselves are seldom seen, as they are ingeniously covered up by the hairs found at the anal extremity of the female, which then dies. The eggs hatch out in August, and the little insects live gregariously. As the cold weather approaches, they betake themselves to shelters which they make, first having secured the leaves by means of threads. Here they remain until the following spring, when they emerge from their retreat and start upon the unopened buds, and eventually on the flowers and leaves. Towards the end of May the colonies break up, and the caterpillars may be found singly and nearly full-fed. Care should be taken not to handle the hairy larvæ, as the hairs sting and cause considerable pain.

The cocoons in which the pupal state is passed may be found between spun-together leaves. As these also contain the irritable hairs of the larvæ, they should be carefully handled.

All fruit trees should be examined in winter, as, being bare, nests, &c., of destructive Moths may be more readily seen and destroyed.

BRUCEA. SYN. *Nima*. This genus comprises five species, natives of tropical Asia, Africa, Australia, and Northern India. They are remarkable for their intensely bitter properties, similar to Quassia.

BRUCHUS. A large genus of Beetles, of which thirteen species are either natives of, or introductions into, this country. The larvæ are very destructive to Peas, Beans, and other Leguminous plants. The characters of the family are set forth under **Beetles.** The chief is that the head is free and produced in front. There is not, however, a distinct beak, as in the Weevils. Two species are very abundant here—*B. pisi* infesting Peas, and *B. rufimanus* Beans; there also occurs another species in goodly numbers, *B. fabæ*, an insect which is very destructive in America alike to the crops when growing, and when housed in the granaries.



By permission of the Board of Agriculture.

FIG. 182. PEA BEETLE (*Bruchus pisi*).

1 and 1a, Beetle, natural size and magnified; 2, Larva, magnified; 3, Pea, showing escape-hole of insect.

B. pisi (Fig. 182) is oblong-ovate and black; the wing-cases, which do not cover the whole of the body, are banded, and covered with greyish-brown pubescence. The Beetles, which are about ⅛in. long, are on the wing at the time the Peas are podding. The eggs are deposited on the newly-formed pods, and in due time the larvæ bore through and feed upon the seeds, gnawing through them except for a very thin skin. The remaining stages are passed in the Peas, and finally the Beetle emerges through the exit-hole practically made by the larvæ before assuming the pupa-state. Such infested Peas germinate badly, if at all. Care, therefore, should be taken to remove all black-specked ones at the time of sowing. According to Prof. Riley, one test is to put the seed-Peas into water, and reject as unsound

Bruchus—*continued.*

those which float. In America, where large quantities of Peas are grown to supply the markets, bi-sulphide of carbon fumes are used to destroy the Beetles which have arrived at maturity. The larvæ are more difficult to reach on account of the exit-hole being covered by a thin lining.

B. rufimanus is equally as destructive to Beans as its relative above-named is to Peas. It has many of the characters of *B. pisi*, but is smaller, and the anterior pair of legs are red (hence *rufimanus*). Both these Beetles fly well, so that, even if they emerge in the stores, which they frequently do, they are able to reach gardens where Beans are grown. The life-history of *B. rufimanus* is practically identical with that given of *B. pisi*.

Remedial measures in either case are out of the question; the cultivator must rely entirely upon preventive ones, by exercising great precaution when seed-sowing.

BRUGMANSIA. *B. floribunda* and *B. parviflora* are synonyms of **Juanulloa aurantiaca** (which *see*).

BRUINSMANIA. A synonym of **Zsertia** (which *see*).

BRUISE. This condition of trees is frequently met with, and often attended with serious consequences. With Apple and Pear trees a Bruise may be given to the branches by tools when working amongst them, thus making them susceptible to the spores of several wound-fungi. With stone-fruit trees a wound is often made when nailing, such a Bruise often inducing "gumming" in Peaches, Nectarines, and also in Plums. It is also probable that the mysterious death of branches in Apricots may be attributed to a similar cause.

BRUNELLA. The correct name of **Prunella** (which *see*).

BRUNFELSIA. ORD. *Solanaceæ.* About a score species, natives of South America and the West Indies, are included in this genus. To those described on pp. 216-7, Vol. I., the following should be added:

B. calycina grandiflora (large-flowered). A fine variety, with larger flowers than in the type. 1891.

B. Hopeana (Hope's). *fl.*, calyx longer than the pedicel, and having five blunt teeth; corolla blue with a yellow throat, the tube very little longer than the calyx. *l.* 1in. to 1¼in. long, elliptic, shortly petiolate. *h.* 1ft. West Indies, 1828. SYN. *Franciscea Hopeana* (B. M. 2829).

B. jamaicensis (Jamaica). *fl.*, corolla yellow, 2in. to 2½in. in diameter, the tube 3in. to 3½in. long (twice as long as the limb), straightish. June. *l.* lanceolate-oblong, bluntly pointed, membranous, at length 3in. to 6in. long, petiolate, veiny. Branchlets puberulous. *h.* 5ft. West Indies, 1844. (B. M. 4237, under name of *B. nitida jamaicensis.*)

BRUNISSURE. *See* **Browning.**

BRUNNICHIA (named in honour of Brunnich, a Danish botanist). SYN. *Rajania.* ORD. *Polygonaceæ.* A monotypic genus. The species, *B. cirrhosa*, is a greenhouse, climbing shrub, with pink flowers in axillary and terminal racemes, and alternate, ovate leaves. It has been introduced, but is probably lost to cultivation.

BRUNSVIGIA. This genus embraces nine species. Flowers copiously umbellate; perianth erect or slightly curved, the tube short. To the information given on p. 216, Vol. I., the following should be added:

B. ciliaris. The correct name is *Buphane ciliaris.*

B. falcata is a synonym of *Ammocharis falcata.*

B. gigantea (gigantic). The correct name of *B. multiflora.* SYN. *B. orientalis.*

B. humilis (dwarf). A synonym of *B. minor.*

B. magnifica (magnificent). *fl.* twenty to thirty in an umbel; perianth tube short, the segments white, with a broad, reddish-purple, central stripe, lanceolate-oblong, reflexed, 3½in. long; peduncle brown, 4in. long. *l.* oblong, deeply channelled acuminate, serrated, 1½ft. to 1¾ft. long, 3½in. broad, recumbent.

Brunsvigia—*continued.*

Bulb large, globose. 1885. (I. H. 1885, 552.) This "is a *Crinum*, either identical with *Forbesianum* or near it" (J. G. Baker).

B. Massaiana (Duc de Massa's). A synonym of *Crinum Massaiana.*

B. minor (lesser). *fl.* twelve to forty in an umbel; perianth pale red, 1¼in. to 1½in. long, the tube very short, the segments lanceolate; stamens as long as the segments; peduncle stout, 6in. to 9in. long. July. *l.* three or four, lorate, 6in. long, 1in. broad. Bulb ovoid, 2in. to 3in. in diameter. 1822. (B. R. 954.) SYN. *B. humilis.*

B. orientalis (Oriental). A synonym of *B. gigantea.*

B. toxicaria. The correct name is *Buphane disticha.*

BRUSSELS SPROUTS. For a general crop, Veitch's Paragon is one of the best, as it produces an abundance of firm, medium-sized sprouts. Other good varieties of the same class are Rosebery, Reading Exhibition, The Bullet, and The Wroxton. Sorts producing very large sprouts are President Carnot and Mein's Victoria.

BRYANTHUS. Three species, natives of the mountains of western North America, are included in this genus. To those described on p. 218, Vol. I., the following should be added. *B. erectus* is a hybrid.

B. Brewerl (Brewer's). *fl.* rose-purple, comparatively large, disposed in short racemes; corolla almost saucer-shaped; pedicels at first shorter than the flowers. Summer. *l.* crowded, three to seven lines long, almost smooth, with strongly revolute, thickened margins. *h.* 9in. to 12in. 1896. A charming little evergreen.

BRYOBIA PRETIOSA. *See* **Gooseberry Mite.**

BRYOBIA PRUNI. *See* **Damson Mite.**

BRYONIA. Including *Bryonopsis.* About a dozen species are included in this genus.

BRYONOPSIS. Included under **Bryonia** (which *see*).

BRYOPHYLLUM. SYN. *Physocalycium.* This genus includes four species of stove, fleshy herbs, shrubby at base, natives of tropical Africa, one being broadly dispersed over the tropical regions of both hemispheres. Flowers white, greenish, or red, rather large, nodding, disposed in many-flowered, paniculate cymes; calyx inflated, cylindrical or quadrangular, shortly five-cleft; corolla urceolate or almost campanulate, the limb shortly five-cleft, spreading; stamens eight, in two series. Leaves opposite, petiolate, simple or imparipinnate, crenate. To the species described on p. 218, Vol. I., the following should be added:

B. proliferum (proliferous). *fl.* 1¼in. long, drooping; calyx large, inflated; corolla longer than the calyx, greenish-yellow, tipped with pink; cymes terminal, proliferous. June. *l.* 1ft. to 1½ft. long, opposite, imparipinnate, with about five opposite pairs of sessile leaflets. Stem 10ft. to 12ft. high, moderately branched. Madagascar, 1858. (B. M. 5417.)

BUBANIA. A synonym of **Limoniastrum** (which *see*).

BUBON (of Linnæus). Included under **Seseli** (which *see*).

BUBROMA. A synonym of **Guazuma** (which *see*).

BUCCO CRENATA. A synonym of **Barosma crenulata** (which *see*).

BUCEPHALON. A synonym of **Trophis** (which *see*).

BUCERAS. Included under **Terminalia** (which *see*).

BUCHINGERA. A synonym of **Cuscuta** (which *see.*)

BUCHNERA VISCOSA. A synonym of **Sphenandra viscosa** (which *see*).

BUCHOSIA. A synonym of **Heteranthera** (which *see*).

BUCKEYE. *See* **Pavia.**

BUCKLER FERN. *See* **Aspidium.**

BUCKLEYA (a commemorative name). SYNS. *Nestronia, Quadriala.* ORD. *Santalaceæ.* A small genus (two or three species) of tall, branched, hardy shrubs, of which one is Japanese, and the other one or two are North American. Flowers dicœcious, the males umbellate and bractless, the females solitary and furnished with four bracts. Fruit ovoid or oblong. Leaves opposite or rarely scattered, shortly petiolate, acuminate, entire, penniveined. *B. distichophylla*, the only species introduced, is one of the rarest of North American plants; it thrives in ordinary soil, and may be increased by cuttings.

B. distichophylla (distichous-leaved). *fl.* greenish, and, as well as the fruit, inconspicuous. *l.* thin, light green, 1in. to 1½in. long, scarcely petiolate, nearly opposite, distichous, lanceolate, acute, pubescent. Branches slender, gracefully spreading. *h.* 6ft. to 12ft. North America, 1890. (G. & F. iii., p. 237, f. 37.)

BUD. *See* **Buds (Flower and Leaf).**

BUDDING. Vines that are deficient in spurs, or strong, healthy ones of poor flavour, may rapidly be improved by means of Buds of the same, or of better varieties being Budded upon them. Taking those that have long bare stems, Buds may be inserted wherever a spur is needed, employing the same variety. The best time for the operation is immediately prior to starting the Vines into growth, taking a Bud with wood attached, as in the ordinary Vine-eye, for propagation. On the opposite side to the eye, about half of the wood is cut away, or in other words to the pith. A corresponding piece of the bark is cut from the Vine-rod, and the Bud is fitted to the cut thus made, taking care that the bark of the Bud and that of the Vine-rod are exactly opposite and close together on one if not on both sides. After tying the Bud firmly in place, the whole, except the eye of the Bud, should be covered with damp moss, keeping this damp daily until the Bud has commenced to grow freely and the union is complete. By this means Vines may not only be made to have plenty of spurs, but worthless sorts rapidly changed into good ones with little trouble or expense.

BUDDLEIA. SYN. *Romana.* This genus embraces about seventy species, natives of South Africa and the warmer parts of America and Asia. To those described on p. 221, Vol. I., the following should be added:

B. auriculata (eared). *fl.* cream-coloured, ¼in. long; cymes many-flowered, shortly pedunculate; thyrse shorter than the leaves. *l.* lanceolate-oblong or ovate-lanceolate, 2in. to 3in. long, entire or serrated, narrowed at base, at length glabrous and shining above. South Africa. Plant tomentose. Greenhouse. (G. C. 1881, xvi., p. 633.)

B. brasiliensis (Brazilian). *fl.* orange, in a dense spike interrupted at base; calyx densely tomentose. *l.* ovate or deltoid-oblong, 6in. long, slightly acute, crenate, narrowed at base and broadly auriculate-connate. Stems somewhat winged and tetragonal. *h.* 10ft. Brazil, 1822. Plant woolly or ferruginously tomentose. (B. M. 2713.)

B. capitata (headed). A synonym of *B. globosa.*

B. carnea (fleshy). A synonym of *B. curviflora.*

B. Colvilei (Sir James Colvile's). *fl.* rose-coloured, with a white ring round the mouth of the corolla, bell-shaped, 1in. to 1¼in. across, disposed in shortly peduncled, thyrsiform, pendulous panicles 1ft. to 1½ft. long. June to August. *l.* 5in. to 7in. long, elliptic-lanceolate, acuminate, crenate-serrulate, shortly petiolate. Sikkim Himalaya. A beautiful, half-hardy shrub or small tree. (B. M. 7449; G. C. 1892, xii., p. 186; Gn., 1893, p. 482; I. H., ser. vi., t. 10; I. H. Pl. t. 18; J. H. S. ser. iii., vol. xxxi., p. 85; R. H. 1893, p. 520.)

B. connata (connate). *fl.* orange, very similar to those of *B. globosa*; heads globose, densely many-flowered, long-pedunculate. May. *l.* oblong-elliptic or almost lanceolate, acuminate, serrated, narrowed and auriculate-connate at base, glabrous above. *h.* 5ft. Peru, 1826. (B. M. 2853.)

B. curviflora (curved-flowered). *fl.* lilac or rosy-violet, ½in. long, ventricose-incurved above the middle; cymes many-flowered; thyrse 6in. to 8in. long, loose. *l.* petiolate, ovate or ovate-lanceolate, 3in. to 5in. long, 1½in. to 2in. broad, long-pointed, cuneate at base, glabrous above. Loo Choo Islands, 1870. Plant tomentose. Hardy. SYN. *A. carnea* (R. H. 1879, p. 90).

B. curviflora (of gardens). A synonym of *B. japonica.*

B. heterophylla (variable-leaved). A synonym of *B. madagascariensis.*

Buddleia—*continued.*

B. insignis (remarkable). *fl.* reddish-lilac, in compact spikes, simple, solitary or fascicled at the tips of the branches. *l.* caducous, opposite or ternate, narrow. A hardy or half-hardy shrub, in habit resembling *Veronica incisa*; it was raised from seeds in 1876. (R. H. 1878, p. 320.)

B. intermedia (intermediate). *fl.* lilac, with a white eye, in simple, drooping spikes as much as 1½ft. long. Summer and autumn. *l.* few, small, coriaceous, very dark green above, glaucescent beneath, narrowed, acute. 1873. A bushy, half-hardy shrub, with slender, recumbent branches. Garden hybrid. (R. H. 1873, p. 150.)

B. japonica (Japanese). *fl.* pale lilac, small, in very dense, arcuate spikes, succeeded by a profusion of fruit. May to August. *l.* elliptic, soft, attaining 10in. in. length and 1½in. to 2½in. in breadth, attenuated to an obtuse point. *h.* 6ft. Loo Choo. Hardy. SYN. *B. curviflora* (of gardens).

B. madagascariensis (Madagascar). *fl.* of a beautiful yellow, in loose cymes, pedunculate and forming a thyrse from 6in. to 12in. long. June to August. *l.* oval, lanceolate, or somewhat cordate, entire or slightly toothed, rough above, ferruginous beneath. *h.* 3ft. to 6ft. Madagascar, 1824. (B. M. 2824.) SYN. *B. heterophylla* (B. R. 1259).

B. pulchella (pretty). *fl.* yellowish-white, tubular, small, disposed in short, terminal panicles. *l.* hastate or irregularly lobed, about 2in. long. *h.* 2ft. Probably South Africa, 1894. A compact, greenhouse bush, quite unlike any other species.

B. variabilis (variable). *fl.* lilac, densely crowded in large, globose heads, which are pedunculate in the upper axils, or collected into erect thryses 4in. to 6in. long; corolla tube ¼in. long. July and August. *l.* opposite, 4in. to 12in. long, oblong or lanceolate, obtuse or caudate. China, 1896. A tall, hardy shrub. (B. M. 7609.)

BUEKIA. A synonym of **Alpinia** (which *see*).

BUENA. A synonym of **Cosmibuena** (which *see*).

BUETTNERIA. SYNS. *Buttneria* and *Byttneria.* *Pentaceros* is included in this genus.

BUFFALO CLOVER. *See* **Trifolium reflexum.**

BUFFALO CURRANT. *See* **Ribes aureum.**

BUFFALO NUT. *See* **Pyrularia oleifera.**

BUFF-TIP MOTH. This handsome Moth, described in Vol. I., is a fairly omnivorous feeder. For Limes, Oaks, Alders, Beech, Birch, Willows, Wych and other Elms, the caterpillars have a marked partiality; but they do not disdain to attack fruit trees, and less often Rose trees. They are gregarious and very

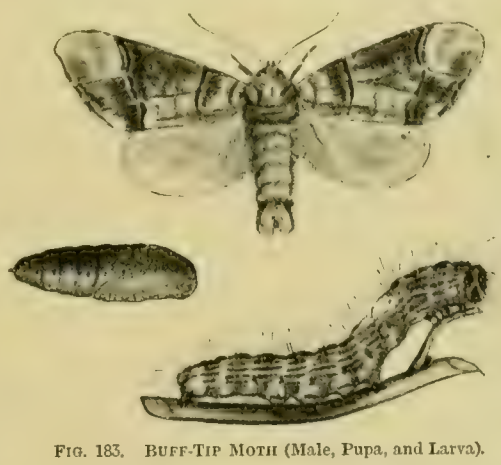


FIG. 183. BUFF-TIP MOTH (Male, Pupa, and Larva).

voracious, and will quickly defoliate a tree. The Moth is nocturnal, and seldom noticed upon the wing; and even when at rest upon a tree-trunk it is most difficult to differentiate. In fact, it more closely approximates to a piece of stick whose end has been obliquely cut off than to a Moth. The caterpillars, feeding as they do in companies, should readily be destroyed. Perfect insect (male), pupa, and larva, are shown at Fig. 183.

BUFO VULGARIS. *See* **Toad.**

BUGINVILLÆA. *See* **Bougainvillæa.**

BUGLE LILY. *See* **Watsonia.**

BUISSON. A name given to a dwarf fruit tree on a low stem, this being closely pruned annually. It is not, however, a profitable form of tree.

BULB. *See* **Bulbs.**

BULB BACTERIOSIS. *See* **Bacteriosis.**

BULBIL. A very small or secondary bulb, especially when produced above the ground, as in some Ferns and Lilies.

BULBINE MACKENII. A synonym of **Eriospermum Mackenii** (which *see*).

BULBINELLA. The correct name of **Chrysobactron** (which *see*).

BULB MITE. *See* **Eucharis Mite.**

BULBOCODIUM AUTUMNALE. A synonym of **Merendera Bulbocodium** (which *see*).

BULBOPHYLLUM. SYNS. *Diphyes* and *Gersinia*. Including *Malachadenia*. Of this genus there are about eighty species, mostly dispersed through tropical Africa and Asia; a few are South American or Australian, and one is found in New Zealand. Pseudo-bulbs usually bearing one or two leaves at apex. To the species described on p. 222, Vol. I., the following should be added:

B. anceps (two-edged). *fl.* moderate-sized; dorsal sepal and petals yellowish, dotted with purple; lateral sepals white, striped with purple; lip purple; racemes lax. *l.* oblong, obtuse. Pseudo-bulbs very broad, compressed. Borneo, 1892. An elegant species. (L. viii., t. 351.)

B. attenuatum (attenuated). *fl.* veined and suffused with maroon-purple on a lighter ground, few; sepals caudate, 1in. to 1¼in. long; lip caudate, ⅜in. long; scape 9in. long, slender, floriferous at apex. October. Borneo, 1892.

B. auricomum (golden-haired).* *fl.* pure white or yellow, sweet-scented; sepals ¼in. long; petals ciliated; raceme 3in. to 6in. long, many-flowered, puberulous; scapes slender, ascending. January. *l.* deciduous. Pseudo-bulbs ⅜in. to 1in. long, sub-cylindric, terete, or obpyriform. India, 1897.

B. barbigerum. An interesting species, whose flower-spikes spring from the base of the pseudo-bulbs. (See Fig. 184.)

B. calamarium (quill-like). *fl.* dirty ochreous-yellow, with a little purple; sepals nearly ½in. long; petals ¼in. long; lip purple, ⅛in. long; racemes 4in. to 6in. long, many-flowered; scapes erect, 1½ft. to 1¾ft. long. *l.* oblong, 6in. to 7½in. long. Psuedo-bulbs quadrangular, 1½in. long, one-leaved. Upper Guinea, 1844. (B. M. 4088.)

B. comosum (tufted). *fl.* white, ⅜in. long, densely villous, perfectly horizontal; racemes inclined, cylindric, truncate, 2½in. by 1½in., resembling a bottle-brush; scape 10in. long, curved. *l.* fleshy, deciduous. Pseudo-bulbs clustered, Pleione-like. Birma, 1892. (B. M. 7283; J. H. 1892, xxiv., p. 141, f. 21.)

B. cupreum (copper-coloured). *fl.* of a uniform copper-yellow; raceme 1in. to 2in. long; scape slender, inclined, slightly curved; sheaths small. Pseudo-bulbs 1in. long, sub-globose. Tenasserim, 1837. (B. M. 5316.)

B. Dayanum (Day's).* *fl.* 1in. in diameter, ciliated with long hairs; sepals green, with purple specks; petals blood-red, with yellow margins; lip green, with red ridges on the disk; scape wanting. *l.* 3in. long, elliptic, reddish beneath. Pseudo-bulbs 1in. long, crowded. Tenasserim, 1855. (B. M. 6119; F. d. S. 2236; Ref. B. 115; R. X. O., ii., t. 144.)

B. Dearei (Lt.-Col. Deare's).* *fl.* about 3in. in diameter; dorsal sepal yellow, with deep orange veins, the lateral ones yellow, suffused with purple; petals clear yellow, veined with deep orange; lip creamy-white, spotted with purple at the base. *l.* small. Pseudo-bulbs ovate, 2in. long. Borneo and Philippines. 1883. (G. C. 1883, xx., p. 108, f. 17; J. H. 1892, xxiv., p. 237, f. 38; L. viii., t. 108.) SYN. *Sarcopodium Dearei*.

B. denticulatum (slightly-toothed). *fl.* small; raceme somewhat deflexed, 1½in. to 1¾in. long, many-flowered; scape slender, 5in. to 6in. long. *l.* linear-oblong, 3in. to 3½in. long. Pseudo-bulbs somewhat distant, ovoid-tetragonal, 1¼in. long, two-leaved. Upper Guinea, 1891.

B. disciflorum (disc-flowered). *fl.* fleshy, 1in. across; sepals and petals greenish-yellow, spotted with reddish-brown; lip covered with purplish-brown warts; scape short, one-flowered. Pseudo-bulbs crowded, ovoid, small, one-leaved. Siam, 1895.

B. elegans (elegant). *fl.* 1in. to 1½in. long; sepals rosy-purple, broad, the upper one shorter and paler than the lateral ones;

Bulbophyllum *continued.*

scapes slender, one-flowered, 1in. to 2in. long. *l.* 3in. to 4in. long, linear-lanceolate. Pseudo-bulbs ½in. to ¾in. long, ovoid, closely set. Ceylon, 1892.

B. Ericssoni (Ericsson's). *fl.* yellowish-white, spotted with brown, 9in. across including the tails, umbellate. *l.* like those of a Stanhopea. Pseudo-bulbs thin, erect, 5in. high. Rhizome long, creeping. Habitat not recorded, 1893. A very striking species.

B. fallax (deceptive). *fl.* dark purple, small; scape 8in. long, bent acutely in the middle. Assam, 1889. An elegant little species.

B. Godseffianum (Godseff's). *fl.* 2in. across; sepals and petals yellow and brown; lip creamy-white, with purple spots, cordate. Habitat not recorded, 1890. Closely allied to *B. Dearei*. SYN. *Sarcopodium Godseffianum* (G. M. 1890, ii., p. 540

FIG. 184. BULBOPHYLLUM BARBIGERUM.

B. grandiflorum (large-flowered). *fl.* solitary, large, densely reticulated with brown on a pale ground; sepals lanceolate-attenuate, 4in. to 5in. long, free, the upper one twice as broad as the lateral ones, strongly arching over at the base, and hanging down in front. *l.* solitary, elliptic, 2½in. to 3in. long. Pseudo-bulbs about 1in. long, distant, four-angled. Rhizome creeping. New Guinea, 1887. More grotesque than beautiful. (L. iii., t. 108.)

B. g. burfordiense (Burford). *fl.*, dorsal sepal green, shaded and mottled at base with greenish-brown, and with large white dots; lateral sepals pale green, olive-tinted at apex. 1895. An extraordinary Orchid.

B. Hookerianum (Hooker's). A synonym of *B. Oreonastes*.

B. inflatum (inflated). *fl.* greenish-yellow, small; sepals ¼in. across; lip recurved; racemes 1in. to 1½in. long, the rachis swollen into an ellipsoid, fleshy body; scapes pendulous, 2in. long. *l.* sessile, lanceolate-oblong, acuminate, 3in. to 4in. long. Pseudo-bulbs strongly quadrangular, 1in. long, one-leaved. Upper Guinea, 1891.

Bulbophyllum—*continued.*

B. lemniscatoides (*lemniscatum*-like). This differs from *B. lemniscatum* only in habit and in the structure of the appendages of the sepals. Java, 1890.

B. lemniscatum (ribboned).* *fl.* small, crowded on a pendulous spike at the end of the scape; sepals dark purple, setose, with an appendage at the base; petals white, with a purple streak; scapes slender, 4in. to 6in. high. *l.* three or four from the base of the pseudo-bulb, 1½in. to 2in. long, elliptic-lanceolate. Pseudo-bulbs ½in. to ¾in. in diameter. Moulmein, 1872. A remarkable species. (B. M. 5921; F. d. S. 2476.)

B. Leysianum (Leys'). *fl.* large, solitary; dorsal sepal yellow, veined with purple, the lateral ones pink and purple, connate. Borneo, 1894. Closely allied to *B. Dearei.*

B. Lobbii siamense (Siamese). The correct name of *B. siamense.* (Ref. B. 116.)

B. longiscapum (long-scaped). *fl.* about 1in. across; sepals and petals pale green; lip reddish-purple; scapes upwards of 1ft. in length. *l.* linear-oblong. Pseudo-bulbs ovoid, ½in. long. Fiji, 1896.

B. macranthum (large-flowered). *fl.* at first of a vinous-red, the dorsal sepal and petals becoming dull blue-purple with broad spots of a dark blue, and the lateral sepals yellowish speckled with bright red on the outer half, large, spreading. March. *l.* shortly petiolate, linear-oblong, thick, coriaceous. Birma, &c., 1844. (B. M. 7203; B. R. 1844, f. 13.)

B. mandibulare (mandible-like). *fl.*, sepals deep bronzy green; petals dark reddish-brown, striped with green; lip yellow and deep reddish-brown. Borneo, 1894. A large and curious species.

B. Medusæ (Medusa's). The correct name of *Cirrhopetalum Medusæ.*

B. neilgherrense (Nilghiri Hills). *fl.* brownish-yellow or green and purple; lateral sepals oblong; auricles of the lip entire or toothed; racemes lax-flowered; scape stout, elongated. January. Nilghiri Hills, 1849. (B. M. 5050.)

B. nigripetalum (black-petaled). *fl.* yellowish and purplish-black; sepals five lines long; lip densely pilose; raceme 3½in. long, many-flowered; scape sub-erect, 1½ft. long. *l.* elliptical-oblong, 4in. to 5in. long. Pseudo-bulbs ovoid-tetragonal, 1½in. to 1½in. long, one-leaved. Lower Guinea, 1891.

B. Obrienianum (O'Brien's). *fl.* yellow, with dark reddish-purple spots, solitary, nearly 2in. in diameter. Pseudo-bulbs ovoid, one-leaved. Rhizome stout. Himalayas, 1892.

B. Oreonastes (Oreonastes). *fl.* yellow, very small; racemes 1½in. to 2in. long; scapes sub-erect, arching, 2½in. to 4in. long. *l.* oblong, 1½in. to 1½in. long, shortly petiolate. Pseudo-bulbs quadrangular, ¾in. long, two-leaved. Upper Guinea, 1894. SYN. *B. Hookerianum.*

B. orthoglossum (straight-lipped). *fl.*, sepals and petals yellowish-green, striped with brown; lip purple. Sarranga Island, 1896. Allied to *B. mandibulare*, but having flowers only about half as large.

B. oxyodon (sharply-toothed). A synonym of *Megaclinium oxyodon.*

B. pavimentatum (tessellated). *fl.* reddish-purple, very minute; racemes dense, 1½in. to 2in. long; scapes slender, 4in. to 6in. long. *l.* oblong or elliptic-oblong, 2½in. to 4in. long. Pseudo-bulbs ovoid, one-leaved. Upper Guinea, 1862. (B. M. 5329.)

B. Pechei (George Peché's). *fl.* coppery-red, rather densely disposed in an elongated raceme; scape decurved, longer than the pseudo-bulbs. January. *l.* linear-oblong or lanceolate, obtuse, slightly dotted beneath. Pseudo-bulbs ovoid, angular. Moulmein, 1891. (B. M. 7286.)

B. perpusillum (very small). One of the smallest species. "The creeping stems are thinner than ordinary silk thread; the bulbs and leaves are one to two lines in length, and the leaves are about half a line in breadth." Madagascar, 1894.

B. pteriphilum (Fern-loving). *fl.* white, small, distichous, numerous on a scape 4in. long. *l.* linear-oblong. Pseudo-bulbs small, oblong. Rhizomes elongated. Penang, 1894.

B. ptiliglossum (fringe-lipped). A species allied to *B. barbigerum*, from which it differs chiefly in having green and purple flowers with hornless anthers and purplish hairs covering the margins of the distinctly lobed lip. Madagascar, 1897.

B. racemosum (racemose). *fl.* ¾in. long; sepals and petals yellowish, spotted with maroon; lip purple, with black dots near the tip; scape 6in. long. *l.* coriaceous, linear-oblong, 4½in. long. Pseudo-bulbs sub-orbicular, 1in. long, one-leaved. Borneo, 1893. Allied to *B. anceps.*

B. rufinum (reddish). *fl.* of a dirty yellow with red streaks on the sepals; raceme 6in. to 10in. long, lax-flowered; scape long, stout, decurved; sheaths large. Pseudo-bulbs 2in. long, oblong. India. (R. X. O. iii., t. 219.)

B. Sanderianum (Sander's). *fl.* pale green, spotted and marked with purple; sepals ½in. long; column white; scape 1½ft. long. July. *l.* 2½in. long, sessile, elliptic-oblong, fleshy. Pseudo-bulbs ¾in. to 1in. long, one-leaved. Pernambuco.

B. saurocephalum (lizard's-head). *fl.* very curious; sepals light ochreous, nerved brown; petals white, with reddish

Bulbophyllum—*continued.*

mid-line and borders, small; lip ochreous, deep purple at base; rachis bright red, thick, clavate, loaded with flowers. Pseudo-bulbs four- or five-angled, one-leaved. Philippine Islands, 1886. An interesting species.

B. siamense is a variety of *B. Lobbii.*

B. Sillemianum (Sillem's). *fl.*, sepals short, blunt, triangular; petals nearly orange, shorter, ligulate-falcate; lip mauve above, whitish beneath, cordate at base, five-angled, with a reflexed apex; column very short. *l.* cuneate-ligulate, acute. Pseudo-bulbs nearly spherical. Birma, 1884.

B. spathaceum (spathe-like). *fl.* light straw-colour; lip brighter; raceme denser; base of the inflorescence sheathed by spathaceous bracts. July. *l.* shorter. Otherwise like *B. apodum.* Birma, 1892.

B. spectabile (remarkable). *fl.* pale green, closely spotted in lines with deep brown; lateral sepals about 1in. long; lip stipitate, recurved, fleshy; scapes 2½in. long, one-flowered. May. Pseudo-bulbs ovoid, shining, ½in. to 1in. long, one-leaved. Assam, 1896.

B. suavissimum (sweetest). *fl.* primrose-yellow, with a golden lip, small, very sweet-scented, secund; raceme elongated, decurved; scape (with raceme) 8in. to 10in. long, very slender. *l.* 4in. long, narrowly oblanceolate. Pseudo-bulbs 1in. long, one-leaved. Upper Birma, 1889.

B. tremulum (trembling). *fl.* white, 1½in. in diameter, with reddish-purple lines and lip, the latter fringed with long hairs; raceme 6in. long, few-flowered. *l.* ovate-lanceolate, 2in. long. Pseudo-bulbs ovate, sub-globose, one-leaved. Nilghiri Hills, 1896.

B. umbellatum (umbellate). A synonym of *Cirrhopetalum guttulatum.*

B. vitiense (Fijian). *fl.* pale yellowish-white, the upper half of the sepals light pink; sepals ½in. long; raceme sub-erect, 6in. to 7in. long, many-flowered. August. *l.* 5in. to 7in. long, linear-oblong. Pseudo-bulbs 1in. to 1½in. long, tetragonal, one-leaved. Fiji, 1892.

The following species, &c., are rarely seen in cultivation, at Kew and elsewhere: *B. apodum, B. aurantiacum, B. bisetum, B. cæspitosum, B. capillipes, E. Careyanum, B. carinatum* (L. xi., t. 495), *B. clandestinum, B. cocoinum* (B. R. 1964), *B. conchiferum, B. cylindraceum, B. densiflorum, B. densum, B. Drallei, B. erectum, B. flavidum, B. fuscum, B. gibbosum, B. Hamelini, B. hirtum, B. intertextum, B. Johannis, B. lasianthum, B. leopardinum, B. Lobbii Henshalli, B. micranthum, B. minutissimum, B.occultum, B. odoratissimum, B. pachyrhachis, B. psittacoglossum, B. purpureum, B. radiatum, B. recurvum, B. Shepherdi, B. striatum, B. tuberculatum, B. variegatum, B. viride,* and *B. Watsonianum.*

BULBOSPERMUM. A synonym of **Peliosanthes** (which *see*).

BULBOSTYLES. The species of this genus are now included under **Eupatorium** and **Brickellia** (which *see*).

BULBS, as popularly understood, furnish some of the most useful and decorative of plants alike for indoor and outdoor gardens. They are amongst the first to flower in spring, and remain with us practically all through winter in specially favoured sites and soils—*Iris stylosa, I. reticulata,* several species of winter Crocuses, and a few others. For the greenhouse and conservatory Bulbs are absolutely indispensable, and the fragrant snow-white Roman Hyacinths are available as cut flowers from November onwards. The window-gardener, again, has in Bulbs the most effective of all early floral subjects. Amongst Bulbs are to be found the loveliest blues that any plants afford—Chionodoxa, Scilla, Hyacinth, Spanish Iris, English Iris, and Muscari. In height Bulbs vary greatly from those of a few inches, which are suited to the rockery, to the giant Eremuruses, all too seldom seen.

The culture of the more popular kinds of Bulbs is of the easiest. The chief mistakes made are in unduly delaying the planting-time, in treating the soil to crude manures, and in the depth at which the Bulbs are actually planted. The majority of Bulbous plants whose culture is undertaken by amateurs are planted far too late. This is especially the case with Narcissus, Crocuses, and Snowdrops. The first-named, if possible, should be in the soil in late August, and the others at the beginning of September. Plenty of roots are then made early, and unless roots are made leaves rather than flowers will be produced. Some Bulbs

Bulbs—*continued.*

quickly deteriorate when kept out of the soil and exposed to dry, cutting winds—Lilies, for instance. Hyacinths and Tulips may be inserted later than most Bulbs. There are also some kinds which are better planted in spring—those which are not sufficiently hardy to be kept outside the year round. Bulbs, generally, should be planted at twice their depth, a little under if anything: one which is, say 2in. in height, should be planted at a depth of 4in. Care should also be taken to maintain as far as possible a uniform depth in planting. A very large proportion flourish best in a light sandy soil, with which has been worked some well-rotted manure. The soil at the time of planting should always be in a nice friable condition: a pasty soil is fatal to the chances of good flowers.

Bulbs may be propagated in various ways. For the amateur gardener propagation by seed cannot be recommended. The time occupied from the period of sowing to that of flowering varies with different genera from two to five or six years. The most popular method of propagation is by means of the young Bulbs which push out from the axils of the scales of the parents, or, in certain cases (Crocuses, for instance), from the axils of scale leaves, when the parent gradually decays.

The number of ways in which Bulbs may be utilised to advantage is great. One form is that of planting certain species on lawns or upon grassy banks. This natural method has much to recommend it, and it has found favour in many of our best public gardens, including Kew. For beds and borders, rockeries, and planting in the shrubberies, Bulbs are eminently adapted, and where brilliant colour-effect is aimed at the brightest should be planted liberally.

For outside culture the following Bulbs should be represented: *Allium Moly*, Snowdrop, Scilla, Snowflake, Snakeshead, Crown Imperial, Madonna Lily, Tiger Lily, Wood Hyacinth, Florists' Hyacinths, *Hyacinthus azureus*, Narcissus, Crocus, Tulip (both florists' varieties and species like *Tulipa retroflexa*, *T. sylvestris*, *T. suaveolens*, and *T. Didieri*), *Milla* (*Triteleia*) *uniflora*, Grape Hyacinths, Spanish Iris, English Iris, Ornithogalum, Red Hot Pokers, Tiger Flowers, Glory of the Snow, and Flower of the West Wind.

Indoors, Narcissus Golden Spur, Bicolor Horsfieldii, and Pallidus Præcox, Roman Hyacinth, Chinese Sacred Lily, *Milla uniflora*, *Freesia refracta alba*, *Scilla sibirica*, and *Allium neapolitanum* may be used along with many others.

Good Bulbs for the rockery are to be found in Crocus species like *speciosus*, *asturicus*, and *sativus*; *Allium Moly* and *A. neapolitanum*; *Muscari conicum*; *Scilla sibirica* and *S. campanulata alba*; *Sternbergia lutea*; *Fritillaria Meleagris*, *F. armena*, and *F. aurea*; *Iris reticulata*; *Galanthus Ikariæ*; *Tulipa persica*; *Romulea speciosa*; *Leucojum vernum*; and *Bloomeria aurea*.

BULLIARDA. Included under **Tillæa** (which *see*).

BULÖWIA. A synonym of **Smeathmannia** (which *see*).

BULRUSH. *See* **Scirpus.**

BUMALDA. A synonym of **Staphylea** (which *see*).

BUNCHOSIA. About twenty-two species of tropical American trees and shrubs are included in this genus. In addition to the species described on p. 223, Vol. I., *B. elliptica* may be mentioned. It is a shrub or small tree, with broadly ovate green leaves, and prominent, curiously-curved nerves, and yellow flowers produced in the axils of the leaves.

BUNT OF WHEAT. Another name for Stinking Smut of Wheat (*Tilletia tritici*).

BUPHANE (a misprint, subsequently corrected by Herbert, for *Buphone*, from *bous*, an ox, and *phone*, destruction, in allusion to the poisonous properties of the plant; but *Buphane* is the name adopted by the authors of the "Genera Plantarum," and by Baker in his "Amaryllideæ"). Originally *Boophane*. Including *Crossyne*. ORD. *Amaryllideæ*. A small genus (two species) of greenhouse, bulbous plants, natives of tropical and South Africa. Flowers long-pedicellate, numerous in an umbel; perianth salver-shaped, with a short tube and equal, linear or lanceolate lobes; stamens inserted at the throat of the perianth-tube; involucral bracts two; scape solid. Leaves loriform, appearing late. For culture *see* **Brunsvigia.**

B. ciliaris (ciliated). The correct name of *Brunsvigia ciliaris*. SYN. *Crossyne ciliaris*.

B. disticha (two-ranked). Cape Poison Bulb. The correct name of *Brunsvigia toxicaria*. SYNS. *Amaryllis ciliaris*, *Hæmanthus toxicarius* (B. M. 1217).

BUPHTHALMUM. Including *Telekia*. Four species, natives of the mountainous regions of Central and Southern Europe, compose this genus. To those described on p. 223, Vol. I., the following should be added. *See also* **Odontospermum.**

B. cordifolium (cordate-leaved). A synonym of *B. speciosum*.

B. speciosum (showy). *fl.-heads* yellow, involucral scales ovate, mucronate. July. *l.* pubescent beneath; lower ones petiolate, cordate, doubly serrated; upper ones ovate, sessile, simply serrated. Stems erect, pubescent. Croatian Mountains, &c., 1739. A strongly-scented, showy perennial, forming bold masses, and suitable for shrubberies, &c. SYNS. *B. cordifolium*, *Telekia speciosa* (B. M. 3466).

BUPLEURUM. Buplever. Including *Tenoria* (of Sprengel). About sixty species, broadly dispersed, are included in this genus, four being indigenous in Britain.

BUPLEVER. *See* **Bupleurum.**

BUR, NEW ZEALAND. *See* **Acæna.**

BURCHARDIA (of Duhamel). A synonym of **Callicarpa** (which *see*).

BURGSDORFFIA. A synonym of **Sideritis** (which *see*).

BURLINGTONIA. According to Bentham and Hooker, this genus is regarded as synonymous with **Rodriguezia**, which comprises about twenty species, natives of tropical America, from Brazil as far as Central America. To those described on p. 225, Vol. I., the following should be added:

B. amœna (pleasing). A synonym of *B. decora*.

B. caloplectron (beautiful-spurred). A synonym of *Rodriguezia caloplectron*.

B. Farmeri (Farmer's). *fl.* white and yellow, freely produced. Early summer. Native country unknown. A pretty species, resembling *B. candida*. It should be grown on a block or in a basket with Sphagnum.

B. Knowlesii (Knowles'). *fl.* white, with a faint tinge of lilac-pink, disposed in long racemes. Autumn. Native country unknown. A scarce but beautiful species, resembling *B. venusta*.

B. pubescens (downy). The correct name is *Rodriguezia pubescens*. (L. 306.)

BURMANNIACEÆ. A natural order of annual or perennial herbs, inhabiting the warmer regions of the globe, and ranking between the *Hydrocharideæ* and the *Orchideæ*. The species are of botanical interest.

BURMESE ROSEWOOD. *See* **Pterocarpus indicus.**

BURNET ROSE. *See* **Rosa spinosissima.**

BURNEYA. A synonym of **Timonius** (which *see*).

BURNING OR SCORCHING OF VINES. The most prolific cause of Scorched foliage or berries in Grapes, is neglecting to open the ventilators early enough in the morning. While the foliage is young and tender, it is astonishing how quickly the damage may be done, and such can only be prevented by the most careful attention on the mornings of bright days by taking care to admit air gradually, so that no checks are given by a sudden

Burning or Scorching of Vines—*continued.*

inrush of cold air. Another factor is defective root-action. In such a case the most careful ventilation will fail to stop Scorching, as the foliage being thin, and lacking in substance, a powerful sun-heat almost invariably causes it to Burn, and the berries to scald. Again, the use of strong manures, highly charged with ammonia, will cause Scorching, especially if the vinery is closed entirely for a few days. To avoid any damage it is advisable to leave a little top ventilation day and night for a week or so, to enable the rank fumes to escape.

BURNT WOOD. *See* **Scolopendrium vulgare.**

BUROMA GUAZUMA. A synonym of **Guazuma ulmifolia** (which *see*).

BURRIELIA (in part). Synonymous with **Bæria** (which *see*).

BURSARIA. Two species, both natives of extra-tropical Australia, are included in this genus. Flowers whitish, rather small, in pyramidal panicles; sepals distinct; petals narrow, spreading nearly to the base; filaments subulate. Leaves small, often fascicled, entire.

BURSERA. Including *Icica* and *Protium*. This genus embraces about forty species, all tropical and mostly American.

BUSBECKIA. A synonym of **Salpichroa** (which *see*).

BUSH. A low and dense shrub.

BUSH HONEYSUCKLE. *See* **Diervilla.**

BUTOMOPSIS (from *Butomus*, an allied genus, and *opsis*, resemblance). SYN. *Tenagocharis.* ORD. *Alismaceæ.* A monotypic genus. The species, *B. lanceolata*, is a stove, annual, bog-loving herb, with milky juice, native of tropical Asia, Africa, and Australia. It bears an umbel of three to twenty white flowers, in bracteate whorls, and has elliptic, acute leaves. Probably it is no longer in cultivation.

BUTONICA SAMOENSIS. A synonym of **Barringtonia samoensis** (which *see*).

BUTTERFLY CYCLAMENS. These are a curious race of Cyclamens, for whose introduction M. de Langhe-Vervaene, of Brussels, is responsible. The plants are characterised by broad, wavy, reflexed petals, fringed at the margin. The usual colours are white, cream, violet, and lilac.

BUTTERFLY FLOWER. *See* **Schizanthus.**

BUTTER-ROOT. *See* **Pinguicula vulgaris.**

BUTTER-TREE, INDIAN. *See* **Bassia butyracea.**

BUTTNERIA. *See* **Buettneria.**

BUTTONS. *See* **Tanacetum vulgare.**

BUTTON WEED. *See* **Spermacoce.**

BUXEÆ. A tribe of **Euphorbiaceæ** (which *see*).

BUXUS. This genus comprises about nineteen species, mostly hardy; six are found in North temperate regions, one in Madagascar, another in tropical Africa, and the rest in the West Indies. To those described on p. 226, Vol. I., the following should be added:

B. chinensis (Chinese). A synonym of *Simmondsia californica.*

B. Fortunei (Fortune's). *l.* long, narrow, sub-cuneiform. Branches numerous, erect. China, 1870. A compact-growing, very hardy, evergreen shrub. SYN. *B. longifolia* (of gardens).

B. Harlandi (Dr. Harland's). *l.* almost sessile, narrow-obovate, emarginate at apex, ten to fifteen lines long. Branchlets pubescent. Hong Kong.

Buxus—*continued.*

B. japonica (Japanese). *l.* ¼in. long, obovate, emarginate at apex, acute at base. Japan.

B. j. microphylla (small-leaved). *l.* spathulate-lanceolate, thrice (or more) as long as broad. Japan.

B. longifolia (long-leaved). A garden synonym of *B. Fortunei.*

B. microphylla (small-leaved). A variety of *B. japonica.*

B. sempervirens. The following varieties may be added: *Handsworthi*, with broad, deep-coloured leaves; *rosmarinifolia*, with narrow leaves, the bush somewhat resembling a dwarf Rosemary; and *thymifolia*, with very small leaves and branches.

B. Wallichiana (Wallich's). *l.* 1¼in. to 2¼in. long, ¼in. to ½in. broad, linear-lanceolate, shortly narrowed at base, truncate or emarginate at apex, slightly mucronulate. India.

BYBLIS (a classical name; Byblis was the daughter of Miletus). ORD. *Droseraceæ.* A genus embracing three or four species of greenhouse herbs, all Australian. Flowers blue, small or large, axillary and long-pedunculate or borne on a scape; calyx five-parted; petals five; stamens five, inserted or free. Leaves clustered, alternate, narrow-linear, terete or filiform; vernation circinate. *B. liniflora* has been introduced, but is probably not now in cultivation.

BYRSONIMA. About ninety species of stove trees or shrubs (often climbing), natives of tropical America, are included in this genus. Calyx five-parted; petals having a reflexed claw and a concave limb; stamens ten, all perfect. Leaves entire, without glands, the stipules often connate in an axillary one, rarely bifid or free.

BYTTNERIA. *See* **Buettneria.**

CABALLERIA. A synonym of **Myrsine** (which *see*).

CABBAGE. For sowing in July or August the following sorts are the best, being reliable, early, and not prone to run to seed in spring: Veitch's Earliest, Best of All, Ellam's Dwarf Early Spring, Mein's No. 1, and Nonpareil Improved. For summer use, any or all of the above are excellent, together with Enfield Market, Early York (referred to in Vol. I.), and Large York. An excellent variety for autumn and early winter use is Chou de Burghley, being of fine flavour and good constitution. For latest supplies Christmas Drumhead will be found the best. In Pickling Cabbage, Red Dutch is still one of the best; Improved Blood should also be grown. The White Cabbages also pickle well, and if sliced Beetroot is mixed therewith a nice red colour is obtained.

CABBAGE CATERPILLARS. To the insects enumerated under this heading in Vol. I. should be added the Caterpillars of the Green-veined White Butterfly (*Pieris napi*, Fig. 185), another common species found upon various *Cruciferæ*, including Cabbages and Watercress. Doubtless, however, it is mistaken by gardeners for the Small White, and is therefore less often recorded as a pest than either *P. brassicæ* or *P. rapæ*. *P. napi* differs chiefly from *P. rapæ* in having green markings along the nervures. This feature, however, varies considerably. The Butterfly, like its relatives already noted, is double-brooded, appearing in April and in July. The larva is green, dotted with black. There is a lateral yellow spot in each segment; the spiracles are black. The pupa is light green, with yellow points, and marked with brown.

Though all three species named feed upon Cabbages, as ordinarily understood, yet they also lay under contribution Broccoli, Cauliflowers, Kales, Turnips, Rape, and Mustard. Nor is it only the leaves of these plants that are destroyed: the seeds and seed-pods of Mustard are frequently attacked. All the species are most plentiful, and therefore correspondingly destructive, in dry weather. In certain seasons, too, the numbers of *P. brassicæ* are reinforced by swarms from the Continent.

Cabbage Caterpillars—*continued*

Patches of Cabbages should be watched in early summer, and hand-picked as far as possible. This, however, is only applicable to comparatively small gardens. The plants should also be dusted with a mixture of lime and soot, in nearly equal parts, the former preponderating. All cruciferous weeds should be removed from gardens and burned. The gardener should also look well for the chrysalides in the positions already indicated, and destroy any found. He is materially assisted in keeping all the above Cabbage Caterpillars at bay by insectivorous birds. Still

FIG. 185. MALE, FEMALE, CATERPILLAR, AND CHRYSALIS OF GREEN-VEINED WHITE BUTTERFLY (*Pieris napi*).

greater assistance, however, is given by certain hymenopterous parasites, whose larvæ live parasitically in the bodies of the larvæ and pupæ of these *Pieridæ*. The parasitic larvæ subsist upon the lymph of their unfortunate host, which, after a time, usually sickens and dies, and the yellow cocoons of the ichneumon-fly are laid upon both larvæ and pupæ of "White" Butterflies. These cocoons should never be removed. *Apanteles glomeratus* is one of the most useful hymenopterous parasites in keeping these Butterflies in check.

CABBAGE GALL WEEVIL (*Ceuthorrhynchus sulcicollis*). The eggs of this very common Beetle are deposited in early summer, and the grubs hatch out in about ten days. They at once set to work, and galls of about the size of Hazel-nuts are eventually formed. When full-fed, the grubs pupate in the soil, or it may be in the roots of the attacked plant. Many preparations have been advocated (of which gas-lime is very effective if applied before the grubs have had time to ensconce themselves in the roots), but preventive as well as remedial measures must be adopted if thorough success is to be attained. Collectors of Beetles know that the

Cabbage Gall Weevil—*continued*.

Cabbage Gall Weevils are to be found early in the season in Charlock. This should always be removed and burnt when in the neighbourhood of Turnip and Cabbage crops. All Cabbage stumps should also be similarly served instead of being consigned to the rubbish-heap, as is usually done. *See also* **Turnip Galls**, Vol. IV.

CABBAGE PALMETTO. *See* **Sabal Palmetto.**

CABBAGE ROSE. *See* **Rosa centifolia.**

CABBAGE-TREE. This name is applied to **Andira inermis** as well as **Euterpe oleracea.**

CABBAGING. Another name for **Heading** or **Hearting** (which *see*).

CABOMBA. The two or three species composing this genus are all American. Flowers white or yellowish, small, on long, solitary, axillary pedicels; sepals three, petaloid; petals three, hypogynous; stamens six. Submerged leaves palmately dissected; floating ones peltate.

CACABUS (from *kakabos*, a red earthen pot; with the prefix *hali*, this name was originally applied to *Physalis Alkekengi*, in reference to the red inflated calyx). SYNS. *Dictyocalyx*, *Streptostigma*, *Thinogeton*. ORD. *Solanaceæ*. A genus embracing about five species of diffuse, prostrate, or ascending, stove or greenhouse annuals, natives of Western tropical and sub-tropical America, being mostly found on the sea-coasts. Flowers violet or white-and-violet, solitary, rather large; calyx shortly five-cleft; corolla campanulate or broadly funnel-shaped, with a five-angled, plicate limb. Berry watery, shorter than the inflated calyx. Leaves long-petiolate, deeply sinuate-toothed. *C. prostratus* (SYN. *Physalis prostrata*) has been introduced, but is probably not now in cultivation.

CACALIA SALICINA. A synonym of **Bedfordia salicina** (which *see*).

CACAO. *See* **Theobroma Cacao.**

CACARA. A synonym of **Pachyrhizus** (which *see*).

CACCINIA (named in honour of G. Caccini, an Italian savant). SYN. *Anisanthera* (of Rafinesque). ORD. *Borragineæ*. A small genus (five species) of hardy, perennial herbs, natives of the Orient. Flowers pedicellate, at length scattered; calyx five-cleft; corolla salver-shaped, with a slender tube and five spreading lobes; stamens five; racemes elongated, bracteate. Nutlets four, or by abortion fewer. Leaves alternate, the margins scabrous-ciliated. *C. glauca*, the only species in cultivation, thrives in any fairly good soil, and may be propagated by divisions.

C. glauca (greyish). *fl.* in racemose cymes; calyx lobes greenish-brown; corolla tube not exserted, the lobes violet-blue, turning red, ½in. long, oblong-lanceolate. *l.* 4in. to 8in. long, shortly petiolate, or the upper ones sessile, elliptic-oblong, sparsely tubercled. Stem below as thick as the thumb. *h.* 1ft. to 3ft. Persia and Afghanistan, 1880. (B. M. 6870.)

CACONAPEA. A synonym of **Herpestis** (which *see*).

CACTI may be described as herbs, shrubs, or trees, with soft flesh and copious watery juice. Root woody, branching, with soft bark. Stem branching or simple, round, angular, channelled, winged, flattened, or cylindrical; sometimes clothed with numerous tufts of spines, which vary in texture, size, and form very considerably; or, when spineless, the stems bear numerous dot-like scars, termed areoles. Leaves very minute, or entirely absent, falling off very early, except in *Pereskia* and several of the Opuntias, in which they are large, fleshy, and persistent. Flowers solitary, except in *Pereskia*, and borne on the top or the side of the stem; they are composed of numerous parts or segments; the sepals and petals are not easily distinguished from each other; the calyx-tube is joined to, or combined with, the ovary, and is often covered with scale-like sepals and hairs or spines; the calyx is sometimes partly united so as to form a tube,

Cacti—*continued.*

and the petals are spread in regular whorls, except in the Epiphyllums. Stamens many, springing from the side of the tube or throat of the calyx, sometimes joined to the petals, generally equal in length; anthers small and oblong. Ovary smooth, or covered with scales and spines, or woolly, one-celled; style simple, filiform or cylindrical, with a stigma of two or more spreading rays, upon which are small papillæ. Fruit pulpy, smooth, scaly, or spiny, the pulp soft and juicy, sweet or acid, and full of numerous small, usually black, seeds.

Tribe I.—*Calyx-tube produced beyond the Ovary. Stem covered with Tubercles, or Ribs, bearing Spines.*

1. MELOCACTUS. Stem globose; flowers in a dense cap-like head, composed of layers of bristly wool and slender spines, amongst which the small flowers are developed. The cap is pesistent, and increases annually with the stem.

2. MAMILLARIA (including *Anhalonium*). Stems short, usually globose, and covered with tubercles or mammæ, rarely ridged, the apex bearing spiny cushions; flowers mostly in rings round the stem.

3. PELECYPHORA. Stem small, club-shaped; tubercles in spiral rows, and flattened on the top, where are two rows of short scale-like spines.

4. LEUCHTENBERGIA. Stem naked at the base; tubercles on the upper part large, fleshy, elongated, three-angled, bearing at the apex a tuft of long, thin, bristle-like spines.

5. ECHINOCACTUS. Stem short, ridged, spiny; calyx-tube of the flower large, bell-shaped; ovary and fruit scaly.

6. DISOCACTUS. Stem short; calyx-tube thin, the throat filled by the stamens; ovary and fruit smooth.

7. CEREUS. Stem often long and erect, sometimes scandent, branching, ridged, or angular; flowers from the sides of the stem; calyx-tube elongated and regular; stamens free.

8. PHYLLOCACTUS. Stem flattened, jointed, and notched; flowers from the sides, large, having long, thin tubes, and a regular arrangement of the petals.

9. EPIPHYLLUM. Stem flattened, jointed; joints short; flowers from the apices of the joints; calyx-tube short; petals irregular, almost bilabiate.

Tribe II.—*Calyx-tube not produced beyond the Ovary. Stem branching, jointed.*

10. RHIPSALIS. Stem thin and rounded, angular, or flattened, bearing tufts of hair when young; flowers small; petals spreading; ovary smooth; fruit a small pea-like berry.

11. OPUNTIA. Stem jointed; joints broad and fleshy, or rounded; spines barbed; flowers large; fruit spinous, large, pear-like.

12. PEREKSIA. Stem woody, spiny, branching freely; leaves fleshy, large, persistent; flowers medium in size, in panicles on the ends of the branches.

The above is a key to the genera on the plan of the most recent botanical arrangement, but for horticultural purposes it is necessary that the two genera *Echinopsis* and *Pilocereus* should be kept up. They come next to *Cereus*, and are distinguished as follow:

ECHINOPSIS. Stem as in *Echinocactus*, but the flowers are produced low down from the side of the stem, and the flower-tube is long and curved.

PILOCEREUS. Stem tall, columnar, bearing long silky hairs as well as spines; flowers in a head on the top of the stem, rarely produced.

With the aid of the above key anyone ought to be able to say to what genus a particular Cactus belongs, and by referring to the descriptions of the species, he may succeed in making out what the plant is. For the classification of Cactuses, botanists rely mainly on their floral organs and fruit.

The stems of Cactuses show a very wide range of variation in size, in form, and in structure. In size, we have the colossal *Cereus giganteus*, whose straight stems, when old, are as firm as iron, and rise with many ascending arms, or rear their tall leafless trunks like ships' masts to a height of 60ft. or 70ft. From this we descend through a multitude of various shapes and sizes to the tiny tufted Mamillarias, no larger than a lady's thimble, or the creeping Rhipsalis, which lies along the hard ground on which it

Cacti—*continued.*

grows, and looks like hairy caterpillars. In form, the variety is very remarkable. We have the Mistletoe Cactus, with the appearance of a bunch of Mistletoe, berries and all; the Thimble Cactus; the Dumpling Cactus; the Melon Cactus; the Turk's Cap Cactus; the Rat's-tail Cactus; the Hedgehog Cactus; all having a resemblance to the things whose names they bear. Then there are the Indian Fig (*Opuntia*), with branches like battledores, joined by their ends; the *Epiphyllum* and *Phyllocactus*, with flattened leaf-like stems; the columnar, spiny *Cereus*, with deeply-channelled stems and the appearance of immense candelabra. Totally devoid of leaves, and often skeleton-like in appearance, these plants have a strange look about them, which is suggestive of some fossilised forms of vegetation belonging to the past ages.

The greater part of Cactuses belong to the group with tall or elongated stems. "It is worthy of remark that as the stems advance in age the angles fill up, or the articulations disappear, in consequence of the slow growth of the woody axis and the gradual development of the cellular substance; so that, at the end of a number of years, all the branches of Cactuses, however angular or compressed they originally may have been, become trunks that are either perfectly cylindrical, or which have scarcely any visible angles."

A second large group is that of which the Melon and Hedgehog Cactuses are good representatives; these have sphere-shaped stems, covered with stout spines. We have hitherto spoken of the Cactuses as being without leaves, but this is only true of them when in an old or fully-developed state. On many of the stems are found upon their surface, or angles, small tubercles, which, when young, bear tiny scale-like leaves. These, however, soon wither and fall off, so that, to all appearance, leaves are never present on these plants. There is one exception, however, in the Barbados Gooseberry (*Pereskia*), which bears true and persistent leaves; but these may be considered anomalous in the order.

The term "succulent" is applied to Cactuses because of the large proportion of cellular tissue, i.e., flesh, of their stems, as compared with the woody portion. In some of them, when young, the woody system appears to be altogether absent, and they have the appearance of a mass of fleshy matter, like a Vegetable Marrow. This succulent mass is protected by a tough skin, often of leather-like firmness, and almost without the little perforations called breathing and evaporating pores, which in other plants are very numerous. This enables the Cactuses to sustain without suffering the full ardour of the burning sun and parched-up nature of the soil peculiar to the countries of which they are native. Nature has endowed Cactuses with a skin similar to that with which she clothes many succulent fruits, such as the Apple, Plum, Peach, &c., to which the sun's powerful rays are necessary for their growth and ripening.

The spiny coat of the majority of Cactuses is no doubt intended to serve as a protection against the wild animals inhabiting with them the sterile plains of America, and to whom the cool, watery flesh of the Cactus would otherwise fall a prey. Indeed, these spines are not sufficient to prevent some animals from obtaining the watery insides of these plants, for we read that mules and wild horses kick them open and greedily devour their succulent flesh. It has also been suggested that the spines are intended to serve the plants as a sort of shade from the powerful sunshine, as they often spread over and interlace about the stems.

There is nothing in the nature or the requirements of Cactuses that should render their successful management beyond the means of anyone possessing a small, heated greenhouse, or even a window recess to which sunlight can be admitted during some portion of the day. In large establishments, such as Kew, it is possible to provide

Cacti—*continued.*

a spacious house (Fig. 186) specially for the cultivation of an extensive collection, where many of them may attain a good size before becoming too big. And it will be evident that where a house such as that at Kew can be afforded, much more satisfactory results may generally be obtained than if plants have to be provided for in a house containing various other plants, or in the window of a dwelling-room.

Apart altogether from size, it is, however, possible to grow a collection of Cactuses, and to grow them well, in a house of small dimensions—given the amount of sunlight and heat which are required by these plants. We sometimes see Cactuses—specimens, too, of choice and rare kinds—which have been reared in a cottager's window or in a small greenhouse, and which in health and beauty have at least equalled what has been accomplished in the most

Cacti—*continued.*

Cactaceous plants—it is possible to keep a collection of tiny Cactuses for years, if only the operations of watering, potting, ventilating, and other matters connected with ordinary plant-growing, are properly attended to.

IN WINDOW RECESSES. In the window recess larger specimens may be grown, and here it is possible to flower successfully many of the plants of the Cactus family. In a living-room window with a south aspect specimens of Phyllocactus, *Cereus flagelliformis*, Epiphyllum, and, in fact, of almost every kind of Cactus, are sometimes to be met with even in England; whilst in Germany they are as popular among the poorer classes as the Fuchsia, the Pelargonium, and the Musk are with us. One of the commonest of Cactuses in the latter country is the Rat's-tail Cactus (*Cereus flagelliformis*), and it is no unusual thing to see a large window of a cottager's dwelling

FIG. 186. SUCCULENT HOUSE AT KEW GARDENS.

elaborately prepared houses. It may be said that these successes, under conditions of the most limited kind, are accidental rather than the result of properly understood treatment; but however they have been brought about, these instances of good cultivation are sufficient to show that success is possible, even where the means are of the simplest or most restricted kind. Whether it be in a large house, fitted with the best arrangements, or in the window of the cottager, the conditions essential to the successful cultivation of Cactuses are practically the same.

IN WARDIAN CASES. To the professional gardener these cases are regarded as playthings. Notwithstanding this, they are a source of much interest, and even of instruction, to many to whom a greenhouse or serious gardening is an impossibility. In these little cases—for which we are indebted to Mr. Boller, a dealer in

thickly draped on the inside with the long, tail-like growths and handsome rose-coloured flowers of this plant. This is only one among dozens of species, all equally useful for window gardening, and all as interesting and beautiful as those above described. The Phyllocactus illustrated (Fig. 187) has been grown as a window plant for twenty years, and has had over twenty blossoms expanded at one time.

IN GREENHOUSES. For the greenhouse proper, Cactuses are well adapted, either as the sole occupants or as suitable for such positions as are afforded by shelves or baskets placed near the roof-glass. If the greenhouse is not fitted with heating arrangements, then, by selecting only those species of Cactus that are known to thrive in a position where, during winter, they are kept safe out of the reach of frost (of which a large number are known), a

Cacti—*continued.*

FIG. 187. GARDEN VARIETY OF PHYLLOCACTUS (Grown as a Window Plant).

good collection of these plants may be grown. In heated structures the selection of kinds may be made according to the space available, and to the conditions under which they will be expected to grow. Fig. 188 represents a section of a house for Cactuses, which will afford a good idea of the kind of structure best suited for them. The aspect is due south.

When grown on their own roots, the Epiphyllums, as well as the pendent-growing kinds of Rhipsalis, and several species of Cereus, may be placed in baskets and suspended from the roof. The baskets should be lined with thin slices of fibrous peat, and the whole of the middle filled with a mixture of peat, loam, and sand. When well managed, some very pretty objects are formed by the Epiphyllums grown as basket-plants. The climbing Cactuses are usually planted in a little mound composed of loam and brick rubble, and their stems either trained along rafters or allowed to run up the back wall of a greenhouse, against which they root freely, and are generally capable of taking care of themselves with very little attention from the gardener.

IN FRAMES. For cultivation in frames, the conditions are the same as for greenhouses. Even when grown in the latter, it will be found conducive to the health and flowering of the plants if, during the summer months, they can be placed in a frame with a south aspect, returning them to the house again on the decline of summer

Cacti—*continued.*

weather. Wherever the place selected for Cactuses may be, whether in a large plant-house, or a frame, or a window, it is of vital importance that the position should be exposed to bright sunshine during most of the day. In Germany, many growers of almost all the kinds of Cactuses place their young plants in frames, which are prepared as follows: In April or May a hot-bed of manure and leaves is prepared, and a frame placed upon it, looking south. Six inches of soil is put on the top of the bed, and in this, as soon as the temperature of the bed has fallen to about 70deg., the young plants are placed in rows. The frames are kept close, even in bright weather, except when there is too much moisture inside, and the plants are syringed twice daily in dry, hot weather. The growth they make under this treatment is astonishing. By the autumn the plants are ready to be ripened by exposure to sun and air, and in September they are lifted, planted in pots, and sent to market for sale. This method may be adopted in England, and if carefully managed, the growth the plants would make would far exceed anything ever accomplished when they are kept permanently in pots.

OUT-OF-DOORS. There are some kinds which may be grown out of doors altogether, if planted on a sunny, sheltered position on a rockery. The most successful plan is that followed at Kew, where a collection of the hardier species is planted in a rockery composed of brick rubble and stones. During summer the plants are exposed; but when cold weather and rains come, lights are placed permanently over the rockery, and in this way it is kept comparatively dry. No fire-heat or protection of any other kind is used, and the vigorous growth, robust health, and floriferousness of the several species are proofs of the fitness of the treatment for this class of plants.

In any garden where a few square yards in a sunny, well-drained position can be afforded for a raised rockery, the hardy Cactuses may be easily managed. To make a suitable rockery, proceed as follows: Find a position against the south wall of a house, greenhouse, or shed, and against this wall construct a raised rockery of brick rubble, lime rubbish, stones (soft sandstone, if possible), and fibrous loam. The rockery, when finished, should be,

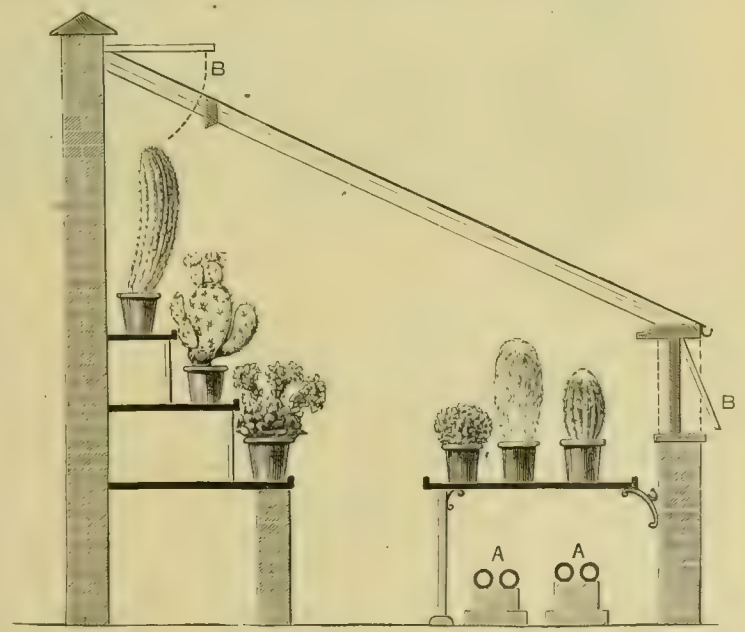

FIG. 188. SECTION OF HOUSE FOR CACTUSES. A, A, Hot-water Pipes; B, B, Ventilators.

Cacti—*continued.*

say, 4ft. wide, and reach along the wall as far as required; the back of the rockery would extend about 2ft. above the ground-level, and fall towards the front. Fix in the wall, 1ft. or so above the rockery, a number of hooks at intervals all along, to hold in position lights sufficiently long to cover the rockery from the wall to the front, where they could be supported by short posts driven in the ground. The lights should be removed during summer to some shed, and brought out for use on the approach of winter. Treated in this manner, the following hardy species could not fail to be a success: *Opuntia Rafinesquii* and var. *arkansana*, *O. vulgaris*, *O. brachyarthra*, *O. Picolominiana*, *O. missouriensis*, *O. humilis*, *Cereus Fendleri*, *C. Engelmanni*, *C. gonacanthus*, *C. phœniceus*, *Echinocactus Simpsoni*, *E. Pentlandi*, and *Mamillaria vivipara*. Cactuses and other succulents are sometimes planted out in beds as summer occupants (see Fig. 189).

Cacti—*continued.*

when placed in a compost of loam and leaf-mould, or loam and peat, yet the growth they make is generally too sappy and weak; it is simply fat without bone, which, when the necessary resting period comes round, either rots or gradually dries up. In preparing soil, therefore, for all Cactuses (except *Epiphyllum* and *Rhipsalis*, which will be treated separately), a good, rather stiff loam, with plenty of grass fibre in it, should form the principal ingredient, sand and, if obtainable, small brick rubble being added—one part of each of the latter to six parts of the former. The brick rubble should be pounded up so that the largest pieces are about the size of Hazel-nuts. Lime-rubbish, *i.e.*, old plaster from buildings, &c., is sometimes recommended for Cactuses, but it does not appear to be of any use except as drainage. At Kew its use has been discontinued, and it is now generally condemned by all good cultivators. Of course, the idea that lime was beneficial to Cactuses

FIG. 189. CACTI AND OTHER SUCCULENTS USED AS OUTDOOR BEDDING PLANTS IN PENGE RECREATION GROUND.

SOIL. The conditions in which plants grow naturally are what we usually try to imitate for their cultivation artificially. At all events, such is supposed to be theoretically right, however difficult it may be found in practice. In Cactuses, however, we have plants for which special conditions are necessary; and, as regards soil, whether we are guided by nature or by gardening experience, we are led to conclude that almost all of them thrive only when planted in one kind, that soil being principally loam. Plants which are limited in nature to sandy, sun-scorched plains or the glaring sides of rocky hills and mountains, where scarcely any other form of vegetation can exist, are not likely to require much decayed vegetable humus, but must obtain their food from inorganic substances, such as loam, sand, or lime. So it is with them when grown in our houses. They are healthiest and longest-lived when planted in a loamy soil; and although they may be grown fairly well for a time sprang from the knowledge that it existed in large quantities in the soil in which the plants grew naturally, and it is often found in abundance, in the form of oxalate of lime, in the old stems of the plants. But in good loam, lime, in the state of chalk, is always present, and this, together with the lime contained in the brick rubble, is sufficient to supply the plants with as much as they require.

For Epiphyllums and Rhipsalis, both of which are epiphytal naturally, but which are found to thrive best in pots in our houses, a mixture of equal parts peat and loam with sand and brick rubble in the same proportion as before recommended, will be found most suitable. Leaf-mould is sometimes used for these plants; but unless really good it is best omitted. The finest Epiphyllums have been grown in a soil consisting almost entirely of a light fibry loam, with the addition of a little crushed bones.

Cacti—*continued.*

POTTING. Cactuses, when healthy, are injuriously affected by frequent disturbance at the roots. On the arrival of the potting season, which for these plants is in April and May, the roots of established plants should be examined, and if they are found to be in a healthy condition, and the soil sweet, they should be replaced in the same pots to continue in them another year. If the roots are decayed, or the soil has become sour, it should be shaken away from the roots, which must be examined, cutting away all decayed portions, and shortening the longest roots to within a few inches of the base of the plant. Cactuses are so tenacious of life, and appear to rely so little on their roots, that it will be found the wisest plan, when repotting them, to cut the roots thoroughly.

The size of pots most suitable is what would be considered small in comparison with other plants, Cactuses preferring to be somewhat restricted as to root-room. This, indeed, is how they are found when wild, the roots generally fixing themselves in the crevices of the rocks or stones about which the plants grow, so that a large specimen is often found to have only a few inches of space in the cleft of a rock for the whole of its roots. When thus limited, growth is firmer and the flowers are produced in much greater profusion than when a liberal amount of space is afforded. The pots should be well drained—about one-fifth of their depth filled with drainage when intended for large, strong-growing kinds, and one-third for the smaller ones, such as Mamillarias. A layer of rough fibry material should be placed over the crocks to prevent the finer soil from stopping the drainage. When filling in the soil, press it down firmly, spreading the roots well amongst it, and keeping the base of the plant only 1in. or so below the surface.

For plants with weak stems, stakes will be necessary, and even stout-stemmed kinds, when their roots are not sufficient to hold them firmly, will do best if fastened to one or two strong stakes till they have made new roots and got firm hold of the soil. Epiphyllums, when grown as standards, should be tied to strong wire supports, those with three short, prong-like legs being most desirable, as, owing to the weight of the head of the plant, a single stake is not sufficient to hold the whole firmly After potting, no water should be given for a few weeks. In fact, if the atmosphere in which the plants are placed be kept a little moist, it will not be necessary to water them till signs of fresh growth are perceived.

For Epiphyllums and Rhipsalis, water will be required earlier than this; but even they are best left for a few days without water after they have been repotted. As soon as fresh growth is perceived, the plants may be well watered, and from this time water may be supplied as often as the soil approaches dryness. Newly-imported plants, which on arrival are usually much shrivelled and rootless, should be potted in rather dry soil and small pots, and treated as recommended above. Cactuses contain an abundance of nourishment stored up in their stems, and upon this they will continue to exist for a considerable time without suffering; and, when their growing season comes round, root action commences whether the soil is wet or dry, the latter being the more favourable.

WATERING. It will have been gathered from what has been previously said in relation to the conditions under which the majority of the plants of the Cactus family grow when wild, that during their season of growth they require a good supply of moisture, both at the root and overhead; and afterwards a somewhat lengthened period of rest, that is, almost total dryness, accompanied by all the sunlight possible, and generally a somewhat high temperature. The growing season for all those kinds which require to be kept dry when at rest is from the end of April to the middle of August, and during this time they should be kept moderately moist, but not constantly

Cacti—*continued.*

saturated, which, however, is not likely to occur if the water is not carelessly supplied, and the drainage and soil are perfect. This treatment corresponds with what happens to Cactuses in a wild state, the frequent and heavy rains which occur in the earlier part of the summer in the American plains supplying the amount of moisture necessary to enable these plants to make fresh growth, and produce their beautiful flowers and spine-clothed fruits. After August, little or no rain falls, and the Cactuses assume a rather shrivelled appearance, which gives them an unhealthy look, but which is really a sign of ripeness, promising a plentiful crop of flowers when the rainy season again returns.

As the sun in England is not nearly so powerful as in the hot plains of Central America and the Southern States of North America, where Cactuses are found in greatest abundance, it will be evident that, if flowers are to be produced, we must see that our plants have a sufficiency of water in early summer, and little or none during the autumn and winter, whilst the whole year round they should be exposed to all the sunlight possible, the temperature, of course, varying with the requirements of the species, whether it is a native of tropical or of temperate regions. It is important that the cultivator should understand that if water is liberally supplied all through the summer, the plants cannot obtain the rest which is necessary to their ripening and producing flowers, as dryness at the root alone is not sufficient to provide this, but must be accompanied by exposure to bright sunlight, which is not possible in England during winter, so that the ripening process must begin before the summer is over.

It is possible to preserve most Cactuses alive by keeping them constantly growing; but, with very few exceptions, such treatment prevents the plants from flowering. The following is what is practised in the gardens where Cactuses are successfully cultivated. For the genera *Cereus*, *Echinopsis*, *Echinocactus*, *Mamillaria*, *Opuntia*, and *Melocactus*, a moist tropical house is provided, and in April the plants are freely watered at the root, and syringed overhead both morning and afternoon on all bright days. This treatment is continued till the end of July, when syringing is suspended, and the water supplied to the roots gradually reduced. By the end of August the plants are placed in a large light frame with a south aspect, except the tall-growing kinds, which are too bulky to remove. In this frame the plants are kept till the summer is over, and are watered only about once a week should the sun be very powerful. The lights are removed on all bright, sunny days, but are kept on during wet or dull weather, and at night. Under this treatment, many of the species assume a reddish appearance, and the thick, fleshy-stemmed kinds generally shrivel somewhat. There is no occasion for alarm in the coloured and shrivelled appearance of the plants: on the contrary, it may be hailed as a good sign for flowers.

A common complaint in relation to Cacti as flowering plants is that they grow all right, but rarely or never flower. The explanation of this is shown by the fact that the plants must be properly ripened and rested before they can produce flowers. On the approach of cold weather the plants which were removed to a frame to be ripened should be brought back into the house for the winter, and kept quite dry at the roots till the return of spring, when their flowers will be developed either before or soon after the watering season again commences.

Hitherto we have been dealing with those genera which have thick fleshy stems, but there still remain the genera *Rhipsalis*, *Epiphyllum*, and *Phyllocactus*, which are not capable of bearing the long period of drought advised for the former. The last-mentioned genus should, however, be kept almost dry at the root during winter, and, if placed in a light, airy house till the turn of the year, the branches will ripen, and set their flower buds much more readily than

Cacti—*continued.*

when they are wintered in a moist partially-shaded house. During summer all the Phyllocactuses delight in plenty of water, and, when growing freely, a weak solution of manure affords them good food. Epiphyllums must be kept always more or less moist at the root, though, of course, when growing freely, they require more water than when growth has ceased for the year, which happens late in autumn. The same rule applies to *Rhipsalis*, none of the species of which are happy when kept long dry. For the several species of *Opuntia* and *Echinopsis*, which are sufficiently hardy to be cultivated on a sunny rockery out of doors, it will be found a wise precaution to place either a pane of glass or a handlight over the plants in wet autumns and during winter, not so much to serve as protection from cold as to shield them from an excess of moisture at a time when it would prove injurious.

TEMPERATURE. The amount of heat required by the different species of Cactus varies very considerably. The majority of Cactuses may be kept alive in one house where all would be subjected to the same temperature, but many of the plants would merely exist, and could not possibly flower. It would be easy to point to several instances of this unsatisfactory state of things. At Kew, for example, owing to the arrangements necessary for the public, it is found convenient to have the majority of the large collection of Cactuses in one house, where the plants present an imposing appearance, but where, as might be expected, a good number of the species very rarely produce flowers. The Cactuses which inhabit the plains of the Southern United States are subjected to a very high summer temperature, and a winter of intense cold; whilst on the other hand the species found in Central and South America do not undergo nearly so wide an extreme, the difference between the summer and the winter temperatures of these countries being generally much less marked. A tropical temperature for Cacti is in summer 70deg., rising to 90deg. with sun heat, night temperature 65deg. to 70deg., in winter 60deg. to 65deg. Temperate: in summer 60deg., rising to 75deg. with sun heat, night 60deg. to 65deg., in winter 50deg. to 55deg. The hardy species will, of course, bear the ordinary temperatures of this country; but, to enable them to withstand a very cold winter, they must be kept as dry as possible. In the colder parts of England it is not advisable to leave any of these plants outside during winter.

INSECT PESTS. Notwithstanding the thickness of skin characteristic of almost every one of the Cactuses, they are frequently attacked by various kinds of garden pests when under cultivation, and more especially by Mealy Bug. There is, of course, no difficulty in removing such insects from the species with few or no spines upon their stems; but when the plants are thickly covered with clusters of spines and hairs, the insects are not easily got rid of. For Cactuses, as well as for other plants subject to this most troublesome insect, various kinds of insecticide have been recommended; but the best, cheapest, and most effectual with which we are acquainted is paraffin, its only drawback being the injury it does to the plants when applied carelessly, or when not sufficiently diluted. A wineglassful of the oil, added to 1gall. of soft water, and about 2oz. of soft soap, the whole to be kept thoroughly mixed by frequently stirring it, forms a solution strong enough to destroy Mealy Bug. In applying this mixture, a syringe should be used, or, if the plants are to be dipped over-head, care must be taken to have the oil thoroughly diffused through the water, or the plant, when lifted out, will be covered with pure paraffin, which does not mix properly with water, but floats upon the surface if allowed to stand for a few moments. The plants should be laid on their sides to be syringed with the mixture, and after they have been thoroughly wetted, they may be allowed to stand for a few minutes before being syringed with pure water. Plants that are badly infested

Cacti—*continued.*

with Mealy Bug should be syringed with the paraffin mixture once a day, for about a week. It is easy to do serious harm to these plants by using a stronger solution than is here recommended, and also by not properly mixing the oil with the soap and water; and the amateur cannot, therefore, be too careful in his use of this excellent insecticide.

For Scale, which sometimes infests these plants, and which is sometimes found upon them when wild, the paraffin may be used with good effect.

Thrips attack *Phyllocactus*, *Rhipsalis*, and *Epiphyllum*, especially when the plants are grown in less shade, or in a higher temperature, than is good for them. Fumigation with tobacco, dipping in a strong solution of tobacco, or sponging with a mixture of soap and water, are either of them effectual when applied to plants infested with Thrips. The same may be said of Green-fly, which sometimes attacks the Epiphyllums.

Hot water (140deg. Fahr.) may also be successfully employed against insects upon Cacti. It should be syringed on in the manner indicated.

A blight, something similar to Mealy Bug, now and again appears on the roots of some of the species of *Echinocactus* and *Cereus*. This may be destroyed by dipping the whole of the roots in the mixture recommended for the stems when infested by Mealy Bug, and afterwards allowing them to stand for a few minutes immersed in pure water. They may then be placed where they will dry quickly, and finally, in a day or two, repotted into new compost, first removing every particle of the old soil from the roots.

DISEASES. Under artificial cultivation there are many conditions more or less unfavourable to the health of plants, and, in the case of Cactuses, very large specimens, when imported from their native haunts to be placed in our glass-houses, soon perish. At Kew, there have been, at various times, fine specimens of some of the largest-growing species, but they have never lived longer than a year or so, always gradually shrinking in size till, finally, owing to the absence of proper nourishment, and to other untoward conditions, they have broken down and rotted. This rotting of the tissue, or flesh, of these plants, is the great enemy to their cultivation in England. When it appears it should be carefully cut out with a sharp knife, and the plant should then be exposed to the influence of a perfectly dry atmosphere for a few days till the wound has dried, when it should be potted in a sandy compost and treated as for cuttings. Sometimes the decay begins in the side of the stem of the plant, in which case it should be cut away, and the wound exposed to a dry air. The cause of this decay at the base or in the side of the stems of Cactuses is no doubt debility, which is the result of the absence of some necessary condition when the plants are cultivated in houses or windows in this country.

Grafted plants, especially Epiphyllums, when worked on to *Pereskia* stocks, are apt to grow weak and flabby through the stem wearing out, or through the presence of Mealy Bug or other insects in the crevices of the part where the stock and scion join. In this case it is best to prepare fresh stocks of *Pereskia*, and graft on to them the best of the pieces of *Epiphyllum* from the old, debilitated plant. It is no use trying to get such plants to recover, as, when once this disease or weakness begins, it cannot easily be stopped.

PROPAGATION. Cactuses may be multiplied from cuttings of the stems, from seeds, and also by means of grafting; this last method is adopted for those species which, under cultivation, are not easily kept in health when growing upon their own roots, or, as in the case of Epiphyllums, when it offers a means of speedily forming large and shapely specimens. From seeds the plants are generally freer in growth than when cuttings are used, although the seedlings are longer in growing into flowering specimens than large cuttings would be.

Cacti—*continued.*

Seeds. Good fresh seeds of Cactaceous plants germinate in from two to four weeks after sowing, if placed in a warm house or on a hotbed with a temperature of 80deg. If sown in a lower temperature, the time they take to vegetate is longer; but, unless in a very low degree of heat, the seeds, if good, and if properly managed as regards soil and water, rarely fail to germinate. For all the kinds, pots or pans containing drainage to within 2in. of the top, and then filled up with finely-sifted loam and sand, three parts of the former to one of the latter, and pressed down moderately firm, will be found to answer. If the soil be moist at the time of sowing the seeds, it will not be necessary to water it for a day or two. The seeds should be scattered thinly over the surface of the soil, and then covered with about ¼in. of soil. Over this, a pane of glass may be placed, and should remain till the seedlings appear above the soil. Should the position where the seeds are to be raised be in a room window, this pane of glass will be found very useful in preventing the dry air of the room from absorbing all the moisture from the soil about the seeds. For the germination of Cactus, and indeed of all seeds, a certain amount of moisture must be constantly

FIG. 190.—SEEDLINGS OF CEREUS.

a, One month after germination. *b*, Two months after germination. *c*, Three months after germination. (Magnified six times.)

present in the soil; and after a seed has commenced to grow, to allow it to get dry is to run the risk of killing it.

The seeds of Cactuses may be sown at any time in the year; but it is best to sow in spring, as, after germinating, the young plants have the summer before them in which to attain sufficient strength to enable them to pass through the winter without suffering; whereas plants raised from autumn-sown seeds have often a poor chance of surviving through the winter, unless treated with great care. The seeds of all Cactuses are small, and therefore the seedlings are at first tiny globular masses of watery flesh, very different from what we find in the seedlings of ordinary garden plants. The form of the seedling of a species of *Cereus* is shown at Fig. 190, and its transition from a small globule-like mass of flesh to the spine-clothed stem, which characterises this genus, is also represented. At *a* we see the young plant after it has emerged from the seed, the outer shell of which was attached to one of the sides of the aperture at the top till about a week before the drawing was made. At *b*, the further swelling and opening out, as it were, of what, in botanical language, is known as the cotyledon stage of development, will be seen; a month afterwards, this will have assumed the shape of a very

Cacti—*continued.*

small *Cereus*. It is interesting to note how the soft fleshy mass which first grows out of the seed is nothing more than a little bag of food with a tiny growing point fixed in its top, and that, as the growing point increases, the food-bag decreases, till finally the whole of the latter becomes absorbed into the young stem, which is now capable of obtaining nourishment by means of its newly-formed roots. In the genus *Opuntia*, the cotyledon stage (see Fig. 749, Vol. II.) of the plant is different from that of the *Cereus*, and is more like that of a Cucumber. Still, though the form is different, the purpose of the two cotyledons and the juicy stem in the seedling *Opuntia* is the same as in the *Cereus*; and, as the growing point develops, the cotyledons shrivel up and fall off, the plant food they contained having passed into that part of the young seedling which was to be permanent.

The seedlings of these two genera serve as an illustration of the process of germination from seed of all the Cactuses; and it must be evident that there is much that is singular and full of interest in raising these plants from seeds. As soon as the seedlings are large enough to be handled, they may be planted separately in small pots, using a compost similar to, but slightly coarser than, that in which the seeds were sown. The soil should be kept moist till the summer is over, and after that, till the return of warm sunny weather, it will be found safest to keep the seedlings on the dry side, a little water only being given at intervals of a week, and only when the sun is shining upon the plants.

To obtain seeds from cultivated plants, it is necessary, in order to ensure fertilisation, that the top of the stigma should be dusted over with the dust-like pollen from the anthers. This may be done by means of a small camel-hair brush; this should be moistened in the mouth and then pushed among the anthers till covered with pollen, which may then be gently rubbed on to the stigma. A warm, sunny morning is the most suitable time for this operation, as fertilisation takes place much more readily under the influence of bright sunshine than at any other time. Some Cactuses have their floral organs so arranged as to be capable of self-fertilisation; still, it is always as well to give them assistance. The night-flowering species must of course be fertilised either at night or very early in the morning. By using the pollen from one kind for dusting on to the stigma of another, hybrids may be obtained, and it is owing to the readiness with which the plants of this family cross with each other that so many hybrids and forms of the genera *Epiphyllum* and *Phyllocactus* have been raised. It would be useless to attempt such a cross as *Epiphyllum* with *Cereus giganteus*, because of their widely different natures; but such crosses as *Epiphyllum* with *Phyllocactus*, and *Cereus flagelliformis* with *C. speciosissimus*, have been brought about.

Cuttings. No plants are more readily increased from stem-cuttings than Cactuses; for, be the cutting 20ft. high, or only as large as a thimble, it strikes root readily if placed in a warm temperature and kept slightly moist. At Kew, it is the common practice, when the large-growing specimens get too tall for the house in which they are grown, to cut off the top of the stem to a length of 6ft. or 8ft., and plant it in a pot of soil to form a new plant. The old base is kept for stock, as it often happens that just below the point where the stem was severed, lateral buds are developed, and these, when grown into branches, are removed and used as cuttings. Large Opuntias are treated in the same way, with the almost invariable result that even the largest branches root freely, and are in no way injured by what appears to be exceedingly rough treatment. Large cuttings striking root so freely, it must follow that small cuttings will likewise soon form roots. In fact, there is not one species in cultivation which may not be easily multiplied by means of cuttings. The nature of a Cactus stem is so very different from the

Cacti—*continued.*

stems of most other plants, that no comparison can be made between them in respect of their root-developing power, the rooting of a Cactus cutting being as certain as the rooting of a bulb. The very soft, fleshy stems of some Cactuses, Echinocactuses for example, should be exposed to the air for a time, so that the cut at the base may dry before it is buried in the soil. If the base of a plant decays, all that is necessary is the removal of the decayed portion, exposure of the wound to the air for two or three days, and then the planting of the cutting in a dry, sandy soil, and placing it in a warm moist house till rooted. All cuttings of Cactuses may be treated in this way. If anything proves destructive to these cuttings, it is an excess of moisture in the soil.

Grafting. The object of grafting is generally either to effect certain changes in the nature of the scion, by uniting it with a stock of a character different from its own, which usually results in the better production of flowers, fruit, &c., or to multiply those plants which are not readily increased by the more ordinary methods of cuttings or seeds. In the case of Cactuses, however, we resort to grafting, not because of any difficulty in obtaining the kinds thus treated from either cuttings or seeds, as we have already seen that all the species of Cactuses grow freely from seed, or are easily raised from cuttings of their stems, nor yet to effect any change in the characters of the plants thus treated, but because some of the more delicate kinds, and especially the smaller ones, are apt to rot at the base during the damp, foggy weather of our winters; and, to prevent this, it is found a good and safe plan to graft them on to stocks formed of more robust kinds, or even on to plants of other genera, such as *Cereus* or *Echinocactus*. By this means, the delicate plants are raised above the soil whence the injury in winter usually arises, and they are also kept well supplied with food by the more robust and active nature of the roots of the plant upon which they are grafted.

Grafting is also adopted for some of the Cactuses to add to the grotesqueness of their appearance; a spherical *Echinocactus* or *Mamillaria* being united to a columnar stem of another kind, so as to produce the appearance of a drum-stick; or a large round-growing species may be grafted on to three such stems, which may then be likened to a globe supported upon three columns. As the species and genera unite freely with each other, it is possible to produce, by means of grafting, some very extraordinary-looking plants, and to a lover of the incongruous and "queer," these plants will afford much interest and amusement. Besides the above, Epiphyllums, and the long drooping Cereuses—such as *C. flagelliformis*—are grafted because of their pendent habit; they are therefore seen to better advantage when growing from the tall erect stem of some stouter kind, than if allowed to grow on their own roots. By growing on a *Pereskia* into a large plant, and then cutting it into any shape desired, we may, by grafting upon its spurs or branches a number of pieces of *Epiphyllum*, obtain large flowering specimens of various shapes in a comparatively short time. For general purposes, it is usual to graft Epiphyllums on to stems, about 1ft. high, of *Pereskia aculeata*, pretty little standard plants being in this way formed in about a year from the time of grafting. As an instance of how easily some kinds may be grafted, we may note what was done with a large head of the Rat's-tail Cactus which had been grown for some years on the stem of *Cereus rostratus*, but which rotted off just below the point of union. On re-grafting this head on to the *Cereus* a little lower down, it failed to unite, and, attributing the failure to possible ill-health in the stock, it was determined to transfer the Rat's-tail Cactus to a large stem of *Pereskia aculeata*, the result being a quick union and rapid, healthy growth since. Upon the same stock some grafts of *Epiphyllum* had previously been worked. In Fig. 191 we have a fine

Cacti—*continued.*

example of this kind of grafting. It represents a stem of *Pereskia Bleo* upon which the Rat's-tail Cactus and an *Epiphyllum* have been grafted.

For most plants the operation of grafting must be carefully and skilfully performed, but in the case of Cactuses very little skill is necessary if one or two rules, which apply to all kinds of grafting, are observed. The period of vigorous growth, and while the sap of both the stock and the scion is in motion, is the most favourable time for the operation. It is then only necessary, in order

FIG. 191. PERESKIA BLEO, with EPIPHYLLUM and CEREUS FLAGELLIFORMIS grafted upon it.

to bring about a speedy union, that the parts grafted should be cut so as to fit each other properly, and then bound or in some way fastened together so that they will remain in close contact with each other till a union is effected. A close atmosphere and, if possible, a little shade, should be afforded the worked plants till the grafts have taken. The ligature used should not be bound round the graft too tightly, or it will prevent the flow of the sap; if bound tightly enough to hold the parts together, and to prevent their slipping, that will be found quite sufficient.

Cacti—*continued.*

Epiphyllums are treated as follow: Cuttings of *Pereskia* are rooted and grown on to the required size, and in the month of September they are headed down, the tops being used as cuttings. Grafts of *Epiphyllum* are then prepared by cutting them to the required length, usually about 6in., and removing a thin slice of the fleshy stem on each side so as to form a flat wedge. The stem of *Pereskia* is then split down about 1in. with a sharp knife, and into this the wedge of the graft is inserted, and fastened either by means of a small pin passed through the stem and graft about half-way up the slit, or by binding round them a little worsted or matting, the former being preferred. The worked plants are then placed in a close handlight or propagating-frame, having a temperature of about 75deg. where they are kept moist by sprinkling them daily with water; they must be shaded from bright sunlight. As soon as a union has been effected, which will be seen by the grafts beginning to grow, the ligature and pin should be removed, and the plants gradually hardened off by admitting air to the box, till finally they may be removed to the house where it is intended to grow them. In a cottage window this operation may be successfully performed if a box with a movable glass top, or a large bell-glass, be used to keep the grafts close till they have taken.

FIG. 192. GRAFT OF MAMILLARIA RECURVA ON CEREUS NYCTICALUS.

FIG. 193. GRAFT OF OPUNTIA DECIPIENS ON O. FICUS-INDICA.

For the spherical-stemmed kinds of *Mamillaria*, *Cereus*, *Echinocactus*, &c., a different method is found to answer. Instead of cutting the base of the graft to a wedge shape, it is simply cut across the base horizontally, or, in other words, a portion of the bottom of the graft is sliced off, and a stock procured which, when cut across the top, will about fit the wound at the base of the scion; the two sliced parts are placed together, and secured either by passing a piece of matting a few times over the top of the graft and under the pot containing the stock, or by placing three stakes around it in such a way that, when tied together at the top, they will hold the graft firmly in position. Another method is that of cutting the base of the scion in the form of a round wedge, and then scooping a hole out in the centre of the stock large enough to fit this wedge; the scion is pressed into this, and then secured in the manner above mentioned.

To graft one spherical-stemmed kind on to three columnar-stemmed ones, the latter must first be established in one pot and, when ready for grafting, cut at the

Cacti—*continued.*

top into rounded wedges, three holes to correspond being cut into the scion. When fixed, the top should be securely fastened by tying it to the pot, or by means of stakes. For this last operation patience and care are necessary to make the stocks and scions fit properly; but if the rules that apply to grafting are properly followed, there will be little fear of the operation failing. In the accompanying illustrations, we have a small *Mamillaria* stem grafted on to the apex of the tall quadrangular-stemmed night-flowering *Cereus* (see Fig. 192), and also a cylindrical-stemmed *Opuntia* worked on a branch of the flat, battledore-like Indian Fig (see Fig. 193).

CADAMBA. Included under **Guettarda** (which *see*).

CADIA (this name is an alteration of the Arabic *Kadi*). SYNS. *Panciatica*, *Spaëndoncea*. ORD. *Leguminosæ*. A small genus (three species are known) of stove, evergreen shrubs, natives of Eastern tropical Africa, Southern Arabia, and Madagascar. Flowers whitish, pink, or purple, solitary in the axils or few in a raceme, pendulous; calyx broadly campanulate, with nearly equal lobes; petals nearly all alike, free, erecto-patent, oblong-ovate or sub-orbicular, very shortly clawed; stamens free, subequal; bracts small; bracteoles wanting. Pods linear, acuminate, two-valved. Leaves impari-pinnate; leaflets small, exstipellate; stipules minute. *C. Ellisiana*, the only species yet introduced, is a small, slender, perfectly glabrous bush, requiring similar culture to **Brownea** (which *see*).

C. Ellisiana (Rev. W. Ellis'). *fl.* rose-red, 1½in. long; petals twice as long as the calyx, obovate-spathulate, convolute, forming a campanulate corolla; racemes short and shortly pedunculate, axillary. December. *l.* alternate, 4in. to 6in. long; leaflets distant, alternate, spreading, very shortly petiolulate, 3in. to 4in. long, elliptic-oblong or lanceolate, obtusely acuminate; petioles very short, swollen at base. Madagascar, 1882. (B. M. 6685.)

CÆRULESCENT. Bluish; the same as Cœrulescent.

CÆSALPINIA. Including *Guilandina*. This genus comprises about thirty-eight species, distributed over the warmer regions of the globe. To those described on p. 232, Vol. I., the following should be added. *See also* **Coulteria** (which should be included hereunder).

C. bicolor (two-coloured). *fl.* reddish-purple. *fr.* a flat, broad pod, 2in. long. *l.* bipinnate. Branches thorny. *h.* 20ft. South America, 1896. This tree yields a fine Brazil wood, valuable for dyeing.

C. Bonducella (Bonducella). *fl.* yellow; petals little exserted; racemes long-pedunculate, simple or paniculate. *l.* 1ft. or more in length; pinnæ usually twelve to sixteen; leaflets oblong, obtuse, mucronate, ½in. to 1in. long, downy beneath. Branches grey-downy. India, &c. SYN. *Guilandina Bonducella*.

C. brasiliensis. The correct name is *Peltophorum Linnæi*.

C. crista (crest). A synonym of *C. sepiaria*.

C. Gilliesii (Dr. Gillies'). *fl.* large and handsome, several in a terminal raceme; petals five, yellow, obcordate, spreading; stamens ten, bright red, free, 4in. to 5in. long. Summer. *l.* alternate, abruptly bipinnate; leaflets scarcely ½in. long, oblong, obtuse. Stem erect, much-branched. Mendoza, South America, 1829. Hardy. SYN. *Poinciana Gilliesii* (B. M. 4006; P. M. B. i. 28).

C. japonica (Japanese). A synonym of *C. sepiaria*.

C. lacerans (torn). A synonym of *Pterolobium indicum*.

C. pulcherrima (very pretty). The correct name of *Poinciana pulcherrima*.

C. sepiaria (hedge-loving). *fl.* yellow, terminal, racemose, drooping; peduncles alternate, filiform, horizontal, one-flowered. May and June. *l.* bipinnate; leaflets sub-sessile, oblong, very obtuse, entire, equilateral, glabrous; petioles and shoots prickly. Stem 6ft. high, arborescent. Japan, 1883. Hardy. (G. C. 1882, iv., p. 513, f. 73; G. M. 21st July, 1888, p. 445.) SYN. *C. crista*.

CÆSIA (named in honour of F. Cæsia). ORD. *Liliaceæ*. A genus including about nine species of greenhouse, tufted herbs, allied to *Arthropodium*, confined to Australia and South Africa. Flowers blue or white, disposed in scattered groups at the sides of the panicle-branches; perianth spirally twisted, the segments

Cæsia—*continued.*

very shortly connate at base, three-nerved, spreading; stamens six; pedicels filiform. Leaves clustered at the base of the stem or under the lower branches of the stem. Rhizome short. *C. vittata*, an Australian species with small, pale blue flowers, has been introduced, but is probably lost to cultivation.

CAILLIEA. A synonym of **Dichrostachys** (which *see*).

CAINITO. A synonym of **Chrysophyllum** (which *see*).

CAJOPHORA [properly **CAIOPHORA**]. Included under **Blumenbachia** (which *see*).

CALADENIA. Including *Leptoceras*. *C. Patersoni* and its form *dilatata* are in cultivation at Kew. *See also* **Glossodia.**

CALADIUM. A very large number of plants have been described as species of this genus, but according to Engler, in Alph. de Candolle's "Monographiæ Phanerogamarum," not more than seven are entitled to rank as such; all are natives of tropical America. The roots of *C. bicolor* and some other species are edible, and are known in tropical countries as Cocoa Roots. Some of the plants formerly included here are now referred to **Anchomanes, Culcasia, Dieffenbachia, Gonatanthus, Montrichardia, Philodendron, Remusatia,** and **Zamioculcas.**

These elegant ornamental stove plants have been improved so much of late years that it looks as if their leaf-colouring had reached the high-water mark of perfection. Where many gardeners fail with these plants is in not thoroughly ripening the tubers in autumn by gradually withholding the water. As soon as the leaves die down the roots should be turned out of the pots and stored in dry silver-sand out of the reach of drip, and in a temperature of 70deg. Propagation is effected by dividing the tubers as soon as growth has commenced. The leaves of most kinds require a neat stick by way of support. To those kinds described on pp. 233-4, Vol. I., the following should be added:

C. adamantinum (adamantine). *l.* deflexed, sagittate, dark green, with white venation, and having numerous white dots along the borders of the veins. Peru, 1891. (I. H. xxxviii., t. 132.)

C. Humboldtii (Humboldt's). The correct name of *C. argyrites.*

C. liliputianum (dwarf). This is apparently a dwarf form of *C. Humboldtii.* It has also been called *C. liliputiense.* 1895.

C. medioradiatum (middle-rayed). *l.* peltate-ovate, acute, notched at the base, dark green, the course of the midrib and its two branches silvery-white; petioles mottled with brown. Colombia, 1891. (I. H. xxxviii., t. 128.)

C. rubescens (reddish). *fl.*, spathe green, with a blackish stripe, 3½in. long. *l.* 6in. long, 2in. broad, ovate-lanceolate, wavy, with short basal lobes, crimson, margined with green. Brazil, 1893.

C. sagittatum (arrow-head-like). *l.* narrow-sagittate, deeply bilobed, dark green, the midrib and some of its branches feathered with red. Brazil, 1891. (I. H. xxxviii., t. 138.)

C. Seguinum (Seguinum). A synonym of *Dieffenbachia Seguine.*

C. venosum (veined). *fl.*, spathe green, 3in. long. *l.* 10in. long, 4in. broad, green, with yellowish nerves and a red margin. Brazil, 1893.

C. violaceum (violet). This is probably identical with *Colocasia antiquorum.*

Varieties. Some of the most noteworthy are included in the enumeration here given:

AVILON*, bright carmine, with darker veinings, margined with green, and freckled with white; BARONNE ADOLPHE DE ROTHSCHILD, crimson, rose spotted; BARONNE CLARA DE HIRSCH*, cream white, with deep rose markings; BARONESS SCHROEDER*, bronzy-gold, rose-tinted, bright crimson veinings, distinct; CANDIDUM*, white, veined dark green; CARDINALE*, crimson, spotted and marked green and yellow; CHARLEMAGNE*, bright red, rose-shaded, and veined dark red; COMTE DE GERMINY, red, with white mottlings; DUCHESS OF FIFE, white, with dark green reticulations, veined bright rose-carmine; EDITH LUTHER*, bronzy-pink, blotched silver, and veined rose-carmine; EXQUISITE*, bright carmine, margined light green; GASPARD CRAYER, deep crimson, with green margin and bright crimson veinings; HER MAJESTY, bright silvery-white, with carmine blotches; LADY STAFFORD NORTHCOTE*, blood-red, shaded crimson; LEONARD BAURE*, pure white, spotted blood-red, veined and flushed pale carmine; MARTIN LUTHER*, rose-crimson, dwarf and compact; MRS. ICETON*, sulphur-yellow, blotched with white, and lined with crimson; MRS. M'LEOD*, violet-maroon footstalks, with bright scarlet blade and dark red veinings; ORIFLAMME, bright red, with green margins; RAYMOND LEMOINIER, carmine-red, with sulphur margin; SILVER CLOUD, silvery-white, spotted with green, with carmine veins; SIR HENRY IRVING*, creamy-white, mottled greenish-white, with rose-pink veins; TENNYSON*, bright green, mottled yellow elegantly blotched.

CALAIS. A synonym of **Microseris** (which *see*).

CALAMAGROSTIS. Smallreed. This genus embraces about five species, broadly scattered over the globe; it was formerly included under *Arundo*, from which it is distinguished principally by the one-flowered spikelets. The British Flora includes three species, *C. Epigeios* and the two described on p. 234, Vol. I.

CALAMINTHA. Including *Acinos.* About forty species, distributed over the North temperate regions, are included in this genus. *C. Acinos* (Basil Thyme), *C. Clinopodium* (Wild Basil), and *C. officinalis* (Common Calamint) are included in the British Flora. To those described on p. 235, Vol. I., the following should be added:

C. glabella (almost glabrous). *fl.* lilac-purple, scented; corolla nearly ½in. long; axils three- to five-flowered. Summer. *l.* oblong or broadly lanceolate, tapering at base, the larger ones serrated. Stems lax or decumbent, 1ft. to 2ft. long. North America. Rockery.

C. mimuloides (Mimulus-like). *fl.* orange-yellow, mostly solitary in the axils, on slender pedicels that are leafy-bracted at base; corolla 1½in. long, with a narrow tube twice the length of the calyx. Summer. *l.* ovate, coarsely serrated, membranous, on slender petioles. *h.* 1½ft. California, 1849. Plant viscidly hirsute.

CALAMOSAGUS. A synonym of **Korthalsia** (which *see*).

CALAMUS. All the 200 species of this genus inhabit tropical or sub-tropical regions; they are mostly found in Eastern Asia. **Dæmonorops** (which *see*) was included here by the authors of the "Genera Plantarum," but has since been separated, and under that genus are now classed *C. accedens* (*D. Draco*), *C. adspersus*, *C. Draco*, *C. fissus*, *C. Hystrix*, *C. Jenkinsianus*, *C. Lewisianus*, and *C. verticillaris.* To those described on p. 235, Vol. I., the following should be added. *See also* **Ancistrophyllum.**

FIG. 194. CALAMUS CILIARIS.

Calamus—*continued.*

C. australis (Southern). *fl.*, panicles long and loose, prickly; male spikes 1in. to 1½in. long; female spikes 3in. to 4in. long. *l.* often above 2ft. long; segments ten to twenty, the lower ones often 1ft. long and 1¼in. broad, the upper ones broader, all shortly acuminate; rachis armed beneath with recurved prickles. Queensland, 1861. "A slender, reclining Palm" (A. Cunningham), "climbing to a great height" (F. Mueller).

C. caryotoides (Caryota-like). *fl.*, inflorescence long and loose, but the partial panicles not loose as in *C. Muelleri*. *l.*, segments much broader than in that species, to which this is allied. Queensland.

C. ciliaris. This very decorative and well-known species, described in Vol. I., is shown at Fig. 194.

C. erectus (erect). *fl.*, spadices 1ft. to 2ft. long, branched, elongated, ending in a flagellum; spikes 6in. to 10in. long; spathels cymbiform. *l.* 12ft. to 18ft. long; leaflets few, linear lanceolate, 1½ft. to 2ft. long, 1½in. to 2in. broad, one-nerved; spines on the full-grown petioles ½in. long and upwards. Stems densely tufted, 12ft. to 18ft. high; internodes 2in. to 3in. long. Sikkim Himalaya, &c. SYN. *C. schizospathus.*

C. gracillimus (very slender). "Foliage very narrow-linear, elongated, spaced at wide distances apart." Habitat not recorded. 1893.

C. grandis (large). A synonym of *Acanthophœnix grandis.*

C. guineënsis (Guinea). *l.* pinnate; segments narrow-lanceolate, supported by spiny leafstalks; young ones cinnamon-brown, changing to deep green. Sikkim, 1884.

C. kentiæformis (Kentia-shaped). "The habit of the plant recalls at once the form and character of *Kentia Forsteriana* [*Howea Forsteriana*], from which circumstance its name was given" (Catalogue of the Compagnie Continentale d'Horticulture, 1884, p. 3). No further description given.

C. Lindeni (Linden's). *l.* pinnatifid; pinnæ unarmed, lanceolate, flat, three-nerved, acuminate, attenuated at base, white-pruinose beneath; petioles and sheaths prickly, the prickles straight, long, brown, thickened at base. Caudex thickened, cylindrical. Indian Archipelago, 1883. (I. H. 1883, t. 499.)

C. Muelleri (Mueller's). *fl.*, main rachis often slender, armed with recurved prickles and bearing a few distant panicles 2in. to 3in. long. *l.* 1ft. to 1½ft. long; segments ten to sixteen, the longest 8in. long and ¾in. broad, all shortly acuminate, the margins having a few minute prickles, the under-surface and rachis occasionally prickly. Stem covered with appressed leaf-sheaths, densely prickly or bristly. Tropical Australia.

C. oblongus (oblong). *fl.*, spadix paniculate. *fr.* pale, cylindrical-oblong, 1in. long. *l.* generally destitute of tendrils; pinnæ scattered, linear-lanceolate, acuminate. Stem climbing. Java, &c., 1857.

C. ovoideus (ovoid). *fr.* ⅝in. to ¾in. long, the spadix having very stout, recurved spikelets. *l.* 14ft. or more in length; leaflets 10in. to 14in. long, ¾in. to 1in. broad, broadly linear, alternate, tricostate, bristly at tip, bright green above, duller beneath; rachis fugaciously scurfy, with hooked spines at back; sheath densely armed with rings of black spines. Stem stout, climbing. Ceylon.

C. Oxleyanus (Oxley's). *l.* 10ft. to 11ft. long exclusive of the long flagellum; leaflets very many, in sub-opposite, distant fascicles, linear-lanceolate, acuminate, 1ft. long, ¾in. broad, five-ribbed; petioles about 2ft. long, stoutly armed (and the sheath excessively so) with large seriate spines and scattered short ones. Malaya.

C. regis (royal). *l.* shining green, borne on mealy petioles. 1886. An elegant and graceful Palm.

C. robustus (robust). *l.* having crowded, ensiform pinnæ; petioles broadly amplexicaul, with brownish-black, membranous margins; spines yellowish-green, disposed in rings of six or eight. Borneo; 1893. (I. H. 1893, t. 169.)

C. Roxburghii (Roxburgh's). A synonym of *C. Rotang.*

C. rudentum (rope-like). *fl.*, male spadix compound; spathe small, prickly. *fr.* oval-globose. *l.* bearing tendrils; pinnæ numerous, equidistant, linear, acuminate; prickles slender. Stem very long, climbing, greyish-white. Amboyna, Java, &c.

C. schizospathus (cut-spathed). A synonym of *C. erectus.*

C. spectabilis (remarkable). *l.* slender, pinnate; pinnæ about five on each side the rachis, not equidistant, oblong, five- to seven-nerved, convex above; petioles very short. 1886. A small-growing, somewhat spiny species, of graceful habit, suitable, when in a young state, for table-decoration.

C. tenuis (slender). The correct name of *C. Royleanus.*

C. trinervis (three-nerved). *l.* pinnate; leaflets alternate, lanceolate, sessile, acuminate, having three prominent, hairy nerves, and two marginal and two intermediate ones less developed; transverse veins conspicuous; petioles thorny, clothed with a deciduous, scale-like tomentum, the sheath ending in a fringe of pointed, brown scales. East Indies, 1883.

Calamus—*continued.*

C. Verschaffeltii (Verschaffelt's). A synonym of *Acanthophœnix rubra.*

C. Alberti, *C. Caroli*, *C. farinosus* (I. H. 1872, t. 109), *C. Laucheanus*, *C. subangulatus*, and *C. Volonteanus* are rare in cultivation.

CALANCHOE. *See* **Kalanchoe.**

CALANDRINIA. About sixty species are included hereunder. To those described on p. 236, Vol. I., the following should be added:

C. elegans (elegant). A garden synonym of *C. discolor.*

C. Lindleyana (Lindley's). A garden synonym of *C. Menziesii.*

C. oppositifolia (opposite-leaved). *fl.* pearly-white, 2in. across, three or four on each stem; petals ten, obtuse, somewhat recurved; scape prostrate, naked. Summer. *l.*, radical ones clustered, 2in. to 4in. long, oblanceolate, obtuse, narrowed into short, thick petioles, green and glistening above, paler beneath. Root fusiform, fleshy. Oregon and California, 1887. Half-hardy perennial. (B. M. 7051; G. C. 1888, p. 601, f. 83.)

C. polyandra (many-anthered). *fl.* reddish-purple, rather large, few together in a terminal raceme. August. *l.* few, thick and fleshy, mostly 1in. to 1½in. long, the lowest broadly linear or almost spathulate, the upper ones narrowly linear. Branches decumbent or ascending. Australia, 1853. SYN. *Talinum polyandrum* (B. M. 4833).

CALANTHE. SYNS. *Amblyglottis*, *Centrosis*, *Ghiesbreghtia*, *Preptanthe*, *Styloglossum.* About forty species, mostly natives of tropical Asia, are comprised in this genus.

The deciduous section includes some of the most useful of winter-flowering Orchids. When grown in a pure atmosphere there are no easier species to manage than these Calanthes. A bright light is essential to their well-being; only sufficient shade is required to prevent the foliage from scorching during the growing season. The fact is, a strong light assists the "bulbs" to properly mature, by hardening the growth in its different stages. Unless a bulb is properly built up flowering will be unsatisfactory, and the well-being of the plant cannot be secured.

In the neighbourhood of London, where fogs and smoky atmosphere are so injurious to plant life in general, the cultivation of this section of Calanthes is practically labour in vain. The unfavourable conditions during the autumn months of the year are such that members of the *C. Veitchii* section (which embrace the darkest forms in cultivation), if fortunate enough to escape destruction before becoming expanded, are so washed out as to colour that they are rendered practically useless. All the winter-flowering section are unable to withstand the effects of even a moderate fog. In the bad state it turns them yellow, and they quickly fall off.

To those described on pp. 236-7, Vol. I., the following should be added:

C. anchorifera (anchor-bearing). *fl.* whitish-ochre; sepals oblong, apiculate; petals very small, rhomboid, obtuse-angled; lateral segments of the lip ligulate, retuse, antrorse, the anterior one bilobed and bent like an anchor; spur filiform; bracts short, velvety; peduncle hairy. Polynesia, 1883.

C. bicolor (two-coloured). A synonym of *C. striata.*

C. biloba (two-lobed). *fl.* numerous, in erect spikes; sepals and petals purplish, with a tinge of yellowish-brown, oblong-lanceolate; lip purple, striped with white, bilobed. *l.* several, large, lanceolate, acute. Pseudo-bulbs cylindrical, elongated. Sikkim, 1839. (W. O. A. iii., t. 378.)

C. bracteosa (bracted). *fl.* white; sepals and petals cuneate-oblong, apiculate; lip with a short isthmus, linear acute lateral segments and a broader anterior one; spur filiform; bracts much developed, sometimes exceeding the flowers. Samoa, 1832.

C. brevicornu (short-horned). *fl.* 1in. to 1½in. across; sepals and petals brownish-purple, with a paler mid-nerve and margin, whitish at base; petals similar to the lateral sepals, but smaller; lip reddish-purple, margined with white; spur very short; racemes many-flowered. August. *l.* oval-oblong or lanceolate, acute, 9in. to 12in. long. Nepal, 1838. (L. S. O., t. 9.)

C. Ceciliæ (Miss Cecilia Weld's). *fl.* light ochre, with a delicate hue of purple; sepals and petals obovate, acute; lip four-cleft, the lateral segments oblong-ligulate, dilated, the middle one subsessile, bifid, the calli very deep yellow; spur slender, filiform. Malayan Peninsula, 1883.

Calanthe—*continued.*

C. Curtisii (Curtis'). *fl.*, sepals and petals rosy outside, white inside, the petals and lateral sepals with rosy borders; lip yellow, with a very short, rather triangular, blunt lobe on each side of the base, the middle segment cuneate, dilated from the narrow base, the callus purple; column white and rosy. *l.* long-petiolate, cuneate-oblong, acute. Sunda Islands, 1884.

C. dipteryx (two-winged). *fl.* suffused rich purple; sepals, rachis, bracts, pedicels, and ovaries puberulous outside; basilar partition of the lip triangular, obtuse, short, scarcely reaching half the breadth of the anterior lacinia; callus purple, in three rows; isthmus very short. Sunda Islands, 1884. Allied to *C. pleichroma.*

C. discolor (two-coloured). *fl.*, sepals and petals claret-coloured, acute; lip white, tinged with pink; scape elongated, racemosely many-flowered. *l.* oblong. Japan, 1837. (B. R. 1840, t. 55.)

C. Foerstermanni (Foerstermann's). *fl.*, sepals and petals yellow, oblong, acute; lip whitish-yellow, reniform, with an apiculus; spur clavate, half the length of the stalked ovary; bracts rather thin, exceeding the flowers; peduncle distantly sheathed, densely racemose at apex. *l.* petiolate, oblong-lanceolate, acute, 3ft. long. Birma, 1883.

C. gracilis (slender). *fl.* greenish-yellow; sepals ½in. to ⅔in. long; lip yellow; column white, short; raceme laxly many-flowered; scape lateral, 8in. to 14in. long. September. *l.* many, 6in. to 12in. long, ovate or lanceolate. Stem 1ft. to 1½ft. high. Khasia Hills and China, 1851. (B. M. 4714.)

C. labrosa (large-lipped). *fl.*, sepals and petals yellow outside, purple within; lip pale purple, with darker spots at base; spur longer than the sepals. *l.* elliptic-lanceolate, acuminate. Pseudo-bulbs 4in. to 8in. long, obpyriform or fusiform, leafing after flowering. Moulmein, 1879. SYN. *Limatodes labrosa.*

C. Langei (Lange's). *fl.* deep yellow, numerous, crowded; dorsal sepal ovate, acute, the lateral ones lanceolate; petals ovate, acute; lip spathulate-obovate, apiculate, with minute deltoid side lobes, and two slight elevations at the base; raceme 3in. to 4in. long; scape shorter than the leaves. *l.* lanceolate, 2ft. long, 2½in. broad. New Caledonia, 1885.

C. natalensis (Natal). *fl.* 1in. to 1½in. in diameter, pale lilac, with a darker, redder lip, or with the sepals and petals white and suffused with lilac towards the margins only; sepals ovate-lanceolate, acuminate; petals shorter and broader; lip about as long as the sepals; raceme 6in. to 8in. long; scape longer than the leaves, erect. *l.* five to seven, all radical, 8in. to 12in. long, 3in. to 5in. broad, elliptic-lanceolate. Natal. Evergreen. (B. M. 6844.) SYN. *C. sylvatica.*

C. Petri is a form of *C. veratrifolia.*

C. proboscidea (snout-like). *fl.* white, changing to lightest ochre, with a few vermilion markings on the lip, the short nail of which descends and the large blade stands at right-angles with it, having four laciniæ; anterior part of the column curved down, like the snout of some insects. Sunda Islands, 1884. Allied to *C. furcata.*

C. rosea (rosy). *fl.* pale rose, shading to white on the lip, which is oblong, flat, retuse; spur straight, obtuse, horizontal; column tomentose; bracts recurved, shorter than the ovary; scape many-flowered, longer than the leaves. *l.* oblong-lanceolate, plicate, glabrous. Pseudo-bulbs fusiform. Moulmein, about 1850. SYN. *Limatodes rosea* (B. M. 5312; F. d. S. xxii., t. 2294; P. F. G. iii. 81).

C. rubens (reddish). *fl.* pink, smaller than in *C. vestita*; dorsal sepal ⅓in. long, mucronate; lip rose-pink, darker at base; raceme about fourteen-flowered; scape 2ft. long, woolly. Pseudo-bulbs 6in. long, 1½in. broad, conical, silvery. Langkawi Island, north of Penang, 1890. (G. C. 1890, vii., p. 576.)

C. Sanderiana (Sander's). *fl.*, sepals and petals pale lilac, shading to lilac-purple at the margin, less than 1in. long; lip rich deep purple with some brown on the crest, three-lobed; racemes many-flowered. *l.* tufted, elliptic-lanceolate, acuminate, 1ft. to 1½ft. long. Eastern tropical Africa, 1892.

C. Sandhurstiana (Sandhurst's). *fl.* deep rose-carmine. A charming hybrid between *C. rosea* and *C. vestita rubro-oculata.* 1884.

C. sanguinaria (bloody). *fl.* dazzling blood-red, the acuminate sepals and the lip being lighter, with blood-red markings, outside pale purple; petals broader than the sepals; middle lobe of lip cuneate, dilated, bilobed; raceme hairy. Pseudo-bulbs hexagonal. 1886. A handsome, seedling form.

C. sanguinea (blood-coloured). *fl.* crimson, the base or "eye" of the lip of an intense crimson outlined with deep rose. 1893. Described as a "grand Calanthe."

C. Sedenii (Seden's). *fl.* large; sepals and petals bright rose; lip the same colour, with a very dark purplish blotch, surrounded by a zone of white, at the base. A hybrid between *C. Veitchii* and *C. vestita rubro-oculata.*

C. Sieboldii. The correct name is *C. striata.*

C. splendens (splendid). *fl.*, sepals and petals rich rosy-red; lip having a distinct crimson or cherry-red shade down the centre. 1893. A hybrid, the parentage of which is not stated.

C. Stevensiana (Stevens'). *fl.* white (changing to buff as they become older), with a rosy-purple spot on the lip; scape erect, hairy, eight- to ten-flowered. Bulbs greyish, stout-jointed. Cochin China, 1833. A pretty species.

C. striata (striated). The correct name of *C. Sieboldii.* (B. M. 7026; L. S. O., t. 9.) SYN. *C. bicolor.*

C. sylvatica (sylvan). A synonym of *C. natalensis.*

C. tricarinata (three keeled). *fl.* 1in. across; sepals whitish, tinged with pale green and rose-pink; petals narrower, the basal half whitish, the apical half stained with rose-pink; lip rose-purple bordered with white, the disk having three white keels; spur obsolete; scape erect, loosely racemose. *l.* broadly oval or oval-oblong, 5in. to 6in. long. Nepal, 1879.

C. Turneri (Turner's). *fl.* pure white, with a deep rose eye, resembling those of *C. vestita*, but more compact, and produced in larger and longer spikes than in that species. Pseudo-bulbs jointed. Java.

C. T. nivalis (snowy). *fl.* wholly white. Birma.

FIG. 195. CALANTHE VERATRIFOLIA.

C. veratrifolia. This time-honoured species, with its bold foliage and erect flower-spikes, is shown at Fig. 195.

C. v. colorans (coloured). *fl.* white; lip changing to ochre, with calli of gamboge-yellow; spur generally bidentate at apex; raceme rather dense, elongated, the rachis, bracts, ovaries, and sepals velvety. India, 1885. (W. O. A. 218.)

C. versicolor (various-coloured). A synonym of *C. Masuca.*

C. vestita Fournieri (Fournier's). *fl.* of a rosy tint, smaller than in the type. 1892. A pretty variety.

C. v. gigantea (gigantic). *fl.* white, large, with a blood-red eye; spike very stout. November to March. Plant larger in all its parts than in the type, retaining its foliage until new growth begins. See Fig. 196.

C. v. luteo-oculata (yellow-eyed). *fl.* white, with a blotch of yellow in the middle of the lip. October to February. (F. d. S. 316; L. J. F. 333; P. M. B. xvi., p. 129; W. S. O. i. 29, upper fig.)

C. v. macroloba (large-lobed). *fl.* pure white, larger and of greater substance than in the type; basilar lobe very broad; lateral calli much developed. May and June. Pacific Islands.

C. v. oculata-gigantea (giant-eyed). A synonym of *C. v. gigantea.*

C. v. porphyrea (porphyry-like). *fl.* wholly blood-crimson, with a deeper-coloured eye.

Calanthe—*continued.*

C. v. Regnierii (Regnier's). *fl.* pure white, with a light ochre lip; lateral laciniæ of the lip divaricate, nearly semi-lunate. Cochin China, 1887. (Gn., xxiv., t. 397.)

C. v. Sanderiana (Sander's). *fl.* disposed in strong, many-flowered spikes; sepals and petals rosy; lip rosy-crimson, similar to that of *C. Regnierii*. Spring. Cochin China.

C. v. Williamsii (Williams'). *fl.*, sepals and petals white, striped and edged with rosy-crimson; lip bright magenta-crimson. 1884. A showy variety. (J. H. 1886, xiii., p. 47, f. 8; W. O. A. iii. 134.)

C. viridi-fusca (fuscous-greenish). A synonym of *Tainea latifolia*.

FIG. 196. FLOWERS OF CALANTHE VESTITA GIGANTEA.

Through the hand of the hybridist many additional varieties have been introduced of late years. It is, however, unfortunate that records of parentage have not in many instances been given, and much confusion exists. The majority of the newer introductions, it is interesting to note, have proved most useful, and in some instances most remarkable.

We append a list of hybrids with their recorded parentage:

Albata	*veratrifolia* and *Cooksonii* (Sander).
Alexanderi	*vestita rubro-oculata* and *Veitchii* (Cookson).
atro-rubens	*William Murray* and *Oakwood Ruby* (Cookson).
Aurora	*Regnierii* and *rosea*.
Barberiana	*vestita and Turnerii* (Barber).
Baron Schröder	*vestita rubro-oculata gigantea* and *Regnierii* (Schröder).
bella	*Turnerii* and *Veitchii* (Veitch).
Bryan	*vestita rubro-oculata* and *Williamsii* (Cookson).
burfordiense	*vestita* and *Veitchii* (Lawrence).
cesta	*vestita nivalis* and *vestita* (Lawrence).
Cooksonii	*Veitchii* and *vestita luteo-oculata* (Cookson).
Darblayana	*Regnierii* and *vestita gigantea* (D'Arblay).
Dominyi	*Masuca* and *furcata* (Veitch).
Eyermanni	*vestita and Veitchii*.
Florence	*bella* and *Veitchii* (Wilshere).
gigas	*Sanderiana* and *vestita rubro-oculata gigantea* (Veitch).
Hallii	*Veitchii* and *vestita rubro-oculata* (Hall).
Harold	*vestita rubro-oculata* and *Veitchii* (Cookson).
Harrisii	*Turnerii* and *Veitchii* (Veitch and Bennett-Poë).
labriosior	unrecorded (Lawrence).
Laucheana	*Sanderiana and veratrifolia*.
lentiginosa	*labrosa and Veitchii*.
Masuca-tricarinata	*Masuca* and *tricarinata* (Veitch).
Moorei	unrecorded (Moore).
Mylesii	*nivalis* and *Veitchii* (Williams).
Oakwood Ruby	*vestita rubro-oculata* and *rosea* (Cookson).

Calanthe—*continued.*

porphyrea	*labrosa* and *vestita rubro-oculata* (Lawrence).
revertens	unrecorded (Lawrence).
Sandhurstiana	*rosea* and *vestita rubro-oculata* (Lawrence).
sanguinaria	*vestita* and *Veitchii* (Lawrence).
Sedenii	*Veitchii* and *vestita rubro-oculata* (Veitch).
Sibyl	unrecorded (Cookson).
splendens	*rosea* and *Bryan* (Cookson).
Veitchii	*rosea* and *vestita* (Veitch).
versicolor	unrecorded (Lawrence).
Victoria Regina	*Veitchii* and *rosea* (Sander).
William Murray	*vestita rubro-oculata* and *Williamsii* (Cookson).

CALANTHE-PHAIO. *See* **Phaio-Calanthe.**

CALATHEA. Upwards of sixty species of this genus have been described; two are natives of Western tropical Africa, and the rest are confined to tropical America. To those described on pp. 237-8, Vol. I., the following should be added. *See also* **Maranta.**

C. bellula (rather pretty). *l.* dark green, festooned with rosy-white along the midrib. Amazons, 1872. SYN. *Maranta bellula*.

C. colorata (coloured). A synonym of *Phrynium coloratum*.

C. cyclophora (wheel-bearing). This is closely allied to *C. zebrina*, but the flowers are white and the leaves green. British Guiana, 1895.

C. inscripta (inscribed). *l.* of an opaque green, decorated with silvery, curved lines. Brazil, 1875. SYN. *Maranta inscripta*.

C. Kummeriana (Kummer's). *l.* dark green, with silvery bands. Brazil, 1875. (B. H. 1875, p. 270, tt. 15-17, f. 1.)

C. Massangeana atrata (dark). *l.* deep olive-green, with light green midrib and secondary veins. 1894.

C. M. florentina (Florentine). *l.* of medium size, bright green, with bands of olive-green and bright silvery veins. 1894.

C. M. metallica (metallic). *l.* of medium size, dark olive-green, with a pale green band along the centre, a green margin, and transverse silvery lines. 1894.

C. Myrosma (Myrosma). A synonym of *Myrosma cannæfolium*.

C. Oppenheimiana (Oppenheim's). *l.* deep green, with white bands. Brazil, 1875. (B. H. 1875, p. 271, f. 3.)

C. picta (painted). *fl.* white, rather longer than the bracts; bracts straw-coloured, margined with red, 1in. to 1¼in. broad, orbicular-obovate; spike cylindric, 4in. long. December. *l.*, lower ones 6in. to 8in. long, oblong or oblong-lanceolate, acuminate, dark green with paler fan-like blotches above, vinous-purple beneath. Stem 3ft. to 4ft. high. Brazil, 1898. (B. M. 7674.)

C. polytricha (many-haired). *fl.* many in a rosette, sessile in the centre of the tuft of leaves; bracts hairy. *l.* green, hairy. Tubers globose. Trinidad, 1894.

C. rufibarba (reddish-bearded). *fl.* golden-yellow, in an oblong spike, long-exserted; corolla lobes linear-oblong; lip bilobed at apex. *l.* on long petioles, biseriate, linear-lanceolate, acuminate, undulated on the margins, violet-tinted beneath. Brazil. Plant stemless. (B. M. 7560.)

C. undulata (waved). *fl.* twin, springing from the base of the inner bracts. *l.* dark green above, with an irregular whitish band along the midrib, purplish beneath, 3¼in. to 4in. long, 1½in. to 2in. broad, oblong-elliptic or nearly elliptic, obtuse. Peru, 1871. Plant dwarf, tufted. (R. G. 1876, t. 852.)

C. vestita (clothed). *fl.* pale yellow, with a long tube, in dense, oblong heads, on stout, hairy peduncles. *l.* broadly lanceolate, 1ft. to 1½ft. long, 3in. to 4in. broad, narrowed to an acute apex and a cuneate base, bright green above, reddish-purple beneath. Bahia, 1872. Plant stemless. (Ref. B. 311.)

C. affinis, *C. angustifolia*, *C. nigro-costata* (I. H. xx., t. 144), *C. picturata*, and *C. tæniosa* (B. H. 1876, p. 83, t. 5), have also been introduced to Continental gardens.

CALATHUS CISTELOIDES. This Ground Beetle is one of those usually carnivorous kinds which forsake their natural diet for one of fruit. It is a black, wingless Beetle, from ⅓in. to ½in. long. The antennæ and wings are more or less red. It is a very common species, and has frequently been found in Strawberry plantations in company with two or three other Ground Beetles. *See* **Strawberry.**

CALCEARIA. A synonym of **Corysanthes** (which *see*).

CALCEOLARIA. Slipper Flower. Including *Jovellana*. This genus embraces nearly 120 species, natives of Western America. Two are also found in New

Calceolaria—*continued.*

Zealand. To those described on pp. 239-40, Vol. I., the following should be added:

C. andina (native of the Andes). *fl.* yellow, disposed in dense, terminal, corymbose panicles; upper lip of the corolla slightly exceeding the calyx, the lower one more than twice as long. April. *l.* ovate, toothed, abruptly narrowed to the petioles, rugose; floral ones small, oblong-lanceolate. Floriferous branches 6in. to 12in. long. *h.* 2ft. Andes of Chili, 1836 and 1893. Half-hardy under-shrub. (B. M. 7326.) SYN. *C. Herbertiana parviflora* (B. R. 1575).

C. arachnoidea-crenatiflora (hybrid). A garden hybrid between the species indicated in the name. 1888.

C. arachnoides alba (white). A variety with white flowers.

C. bellidifolia (Daisy-leaved). *fl.* yellow and red, ¾in. across; lower lip of the corolla large, orbicular. *l.* ovate, entire; radical ones long-petiolate; cauline ones narrowed to a shorter petiole. Stems slender, varying from 2in. to 12in. in length. Andes of Chili, 1861. Hardy perennial.

C. connata (connate). A synonym of *C. petiolaris.*

C. crenata (crenate). *fl.* ample, but smaller than in *C. amplexicaulis* (to which this species is allied); corolla lids nearly closed; panicle loosely sub-corymbose. Summer. *l.* broadly lanceolate, acuminate, 2in. long, crenate and revolute on the margins, pale beneath. Branches slightly viscous-hairy. Quito. Sub-shrub. SYN. *C. floribunda.* (B. M. 4154.)

C. crenatiflora (crenate-flowered). *fl.* yellow, spotted, like those of *C. corymbosa*, but fewer and larger, in a loose corymb. June. *l.*, radical ones petiolate, ample, ovate, denticulate or deeply crenate, cuneate at base; stems few-leaved, villous. Chiloe, 1831. Hardy perennial. The parent of many of our garden forms. (B. M. 3255; B. R. 1609.) SYN. *C. pendula* (S. B. F. G. ser. ii. 155).

C. floribunda (abundant-flowered). A synonym of *C. crenata.*

C. Herbertiana parviflora (Herbert's small-flowered). A synonym of *C. andina.*

C. Kellyana (Kelly's). *fl.* orange-yellow, profusely dotted with brown, 1in. across, borne in twos or threes at the tops of the stems. *l.* Mimulus-like. Stems downy, creeping. 1883. A curious hybrid, well adapted for the rockery.

C. pendula (drooping). A synonym of *C. crenatiflora.*

C. petiolaris (petiolate). *fl.* yellow, with connivent lips, disposed in an ample, loose, flexuous, branched panicle. *l.*, lower ones ovate, narrowed at base to a winged petiole, deeply or doubly toothed, rugose; upper and floral ones broadly cordate, amplexicaul, toothed. *h.* 3ft. Chili, 1824. Biennial or perennial. SYN. *C. connata* (B. M. 2876; L. B. C. 1807).

C. polifolia (Polium-leaved). *fl.* yellow; corolla lips connivent, about twice as long as the calyx; peduncles corymbose. July. *l.* rather thick, scarcely ¼in. long, petiolate, broadly ovate or oblong. *h.* 1ft. Chili, 1827. A white-tomentose under-shrub, much branched at base. (B. R. 1711.)

C. punctata (dotted). *fl.* purple and yellow; lips deeply connate, the upper one thrice as long as the calyx; panicle large, many-flowered. *l.* 2in. to 3in. long, petiolate, ovate, doubly toothed, narrowed at base, pubescent or glabrous, paler beneath. Branchlets lightly pubescent. South Chili, 1863. Shrub. (B. M. 5392.)

C. Sinclairii (Dr. Sinclair's). *fl.* in loose, sub-corymbose heads; corolla pale lilac or flesh-coloured externally, spotted reddish-purple within, ¼in. to ½in. in diameter, between hemispherical and campanulate. June. *l.* membranous, long-petiolate, 2in. to 4in. long, oblong or ovate-oblong, crenate-toothed or lobulate. New Zealand, 1881. A straggling, half-hardy herb. (B. M. 6597.)

Varieties. The yearly improvement in the Calceolaria consists in the production of improved strains from seeds. The improvements are as follow: Plants of a dwarfer habit, a much larger quantity of blossom from a plant, and the flowers themselves richer and more varied in colour, larger in size, and much better formed. When a variety of a distinct colour has been obtained, and its qualities are such that it may fairly be considered a good advance on existing varieties, seeds are saved from it; and if it has been kept free from the influence of foreign pollen the seedlings can be depended upon to be much like the parent. In this way strains of distinct colours are obtained. Named collections are not to be had, as the expense of propagating them from cuttings or offsets is too much to compensate the growers. The plants can be propagated during the summer months most surely by

Calceolaria—*continued.*

layering, while placed in hand-lights or frames on the north side of a wall or fence. From six to a dozen plants may be obtained from one old stool during summer. Cuttings will strike in sandy soil if they are placed in closed hand glasses in autumn.

CALCOA. A synonym of **Geitonoplesium** (which *see*).

CALDASIA HETEROPHYLLA. A synonym of **Bonplandia geminiflora** (which *see*).

CALDCLUVIA. *Dieterica* is synonymous with this monotypic genus.

CALEA (of Gærtner). A synonym of **Neurolæna** (which *see*). *C. aspera* is a synonym of *Melanthera deltoidea.*

CALEACTE. Included under **Calea** (which *see*).

CALEANA. SYN. *Caleya.* The three species of this genus are rarely met with.

CALENDULA. SYN. *Caltha* (of Mœnch). To this genus upwards of a score species have been referred, ranging from the Canary Islands to Persia, and from Central Europe to the Mediterranean; but some of them are now only regarded as varieties. Several plants formerly included hereunder are now classed under **Dimorphotheca.**

C. hybrida (hybrid). A synonym of *Dimorphotheca pluvialis.*

C. officinalis. Of this species there are several improved garden varieties.

CALEYA. A synonym of **Caleana** (which *see*).

CALIFORNIAN NUTMEG. *See* **Torreya californica.**

CALIFORNIAN TULIP. *See* **Calochortus.**

CALIMERIS. Included under **Aster** (which *see*).

CALINEA. Included under **Doliocarpus** (which *see*).

CALIPHRURIA. This genus includes only a couple of species, allied to *Eucharis*, and confined to the Andes. Leaves oblong, petiolate.

C. subedentata. The correct name of the plant so described on p. 241, Vol. I., is *Eucharis subedentata.*

CALLA. Several ornamental garden plants erroneously classed hereunder will be found described under their correct name, **Richardia.**

CALLIANASSA. A synonym of **Isoplexis** (which *see*).

CALLIANDRA. SYN. *Anneslea* (of W. Hooker). Of the eighty species of this genus, one is a native of the East Indies, and the rest are all tropical or sub-tropical American. To those described on p. 242, Vol. I., the following should be added:

C. bicolor (two-coloured). *fl.* nearly glabrous; stamens white at base, purple at apex; peduncles axillary, solitary. *l.*, pinnæ four to six pairs; leaflets many pairs, ¼in. long, oblong-linear, glabrous or ciliated. Young leaves and branches pilose. Uruguay. SYN. *C. diademata* (L. J. F. iii. 305-6).

C. brevipes (short-stalked). *fl.* pink; corolla broadly campanulate; peduncles short, terminal, somewhat fascicled. October. *l.*, pinnæ one pair; leaflets very numerous, ⅛in. to ¼in. long. Brazil. (B. M. 4500; L. J. F. 8.)

C. diademata (diademed). A synonym of *C. bicolor.*

C. gracilis (slender). *fl.* yellowish-white, sessile; heads twenty- to thirty-flowered, on erecto-patent, downy peduncles; stamens thirty to forty, six to eight times as long as the calyx. *l.* short-stalked, abruptly bipinnate; pinnæ two or three pairs; leaflets four to six pairs, ¼in. to 1¼in. long, obovate-oblong, mucronate Colombia, 1870. A copiously-branched shrub. (Ref. B. 294.)

C. hæmatocephala (bloody-headed). *fl.* borne in a small head; calyx and corolla almost concealed by the filaments, which form a ball of scarlet threads. February. *l.* copious, petiolate.

Calliandra—*continued.*

unijugate; each pinna about 5in. long, having seven to ten pairs of opposite pinnules, the lowest and shortest 1in. long. Habitat uncertain, 1857. (B. M. 5181.)

C. tergemina (three-fold). *fl.* white, disposed in globose, pedunculate heads; corolla ½in. long; filaments tipped red. Spring. *l.* one-and-a-half pairs (one of the lower pair abortive), obliquely ovate-oblong, blunt, ½in. to 1in. long. Branches zigzag. Tropical America, 1887.

CALLIANTHEMUM (from *kallos*, beauty, and *anthemon*, a blossom). ORD. *Ranunculaceæ*. A genus embracing what were formerly described as five species of alpine herbs, natives of the mountains of Europe and Asia, but which Sir J. Hooker now regards as mere forms of one. It is a highly glabrous, almost stemless, perennial. Petals ten to fifteen, broad or narrow. Leaves radical, triangular, decompound. Rhizome rather thick. The beautiful variety here described requires similar culture to **Anemone** (which *see*).

C. rutæfolium anemonoides (Rue-leaved, Anemone-like). *fl.* white or pale rose-coloured, 1in. to 1½in. in diameter; sepals five, orbicular; petals ten to fifteen, linear-oblong; peduncle single-flowered, naked, or bearing a small, sessile leaf. March. *l.* long-petiolate, triangular, 5in. across, bipinnatifid; lobes variable. Styria, &c. (B. M. 7603.)

CALLICARPA. SYNS. *Burchardia*, *Spondylococca*. This genus embraces about thirty species, mostly found in Eastern Asia, Malaya, and North Australia; a few are Polynesian, Columbian, and West Indian. To those described on p. 242, Vol. I., the following should be added:

C. cana (hoary). *fl.* purple, in a globose cyme 1in. to 2in. in diameter. *fr.* deep purple, finally black. *l.* broadly elliptic, shortly acuminate at both ends, 4½in. long, 2½in. broad, sharply crenate-toothed, glabrous above, stellate-tomentose beneath. *h.* 3ft. Penang, 1799. Stove shrub. (B. M. 2107.) SYN. *C. tomentosa*.

C. tomentosa (downy). A synonym of *C. cana*.

CALLICOCCA (of Schreber). A synonym of **Cephaelis** (which *see*).

CALLICOMA. *Calycomis* (of Brown) is synonymous with this genus.

CALLICORNIA. A synonym of **Leyssera** (which *see*).

CALLICYSTHUS. A synonym of **Vigna** (which *see*).

CALLIGLOSSA. Included under **Layia** (which *see*).

CALLIGONUM. SYN. *Calliphysa*. Flowers solitary or fascicled, without bracteoles. Leaves alternate, linear or subulate.

CALLIMORPHA DOMINULA. *See* **Tiger Moths.**

CALLIPHRURIA. *See* **Caliphruria.**

CALLIPHYSA. A synonym of **Calligonum** (which *see*).

CALLIPSYCHE. According to J. G. Baker, this genus consists of only the three species described on p. 242, Vol. I., all of which are found on the Andes. Flowers, many in an umbel; perianth funnel-shaped, the tube short, the segments equal, oblanceolate-oblong; stamens affixed at the throat of the perianth, much exserted; peduncle hollow; spathe valves ovate-lanceolate. Leaves thin, oblong, petiolate.

CALLIRHOË. Seven species of this genus are known. Calyx five-cleft; petals purplish, pink, or white, cuneiform, truncate, and often fimbriate-denticulate. Leaves mostly lobed or parted. To the species described on p. 243, Vol I., the following should now be added:

C. alcæoides (Alcæa-like). *fl.* rose-coloured, or white, corymbose, on slender peduncles; involucel none. *l.*, lower ones triangular-cordate, incised; upper ones five- to seven-parted, laciniate; uppermost ones divided into linear segments. Stems slender,

Callirhoë—*continued.*

1ft. high, from a perennial root. North America. SYNS. *C. macrorhiza*, *Sida alcæoides*. There are garden forms of this varying from pure white to purplish-carmine.

C. involucrata linearifloba (linear-lobed). *fl.*, petals lilac in the centre, margined white on each side, broad, obcuneate. *l.* pedately-parted, dark green, roundish in outline, cut in a bipinnatifid manner almost to the base into narrow lobes ¼in. wide. Stems numerous, trailing. Texas, 1884.

C. macrorhiza (large-rooted). A synonym of *C. alcæoides*.

C. pedata compacta (compact). A compact, garden variety, having flowers of a delicate blush. 1887. (R. G. 1224.)

C. p. nana (dwarf). A dwarfer and much more floriferous plant than the type.

C. spicata (spiked). A synonym of *Sidalcea malvæflora*.

CALLISIA (from *kallos*, beauty). ORD. *Commelinaceæ*. A small genus (four species) of slender, creeping, stove herbs, natives of tropical America, allied to *Tradescantia*. Flowers small, usually cymose; sepals and petals distinct; stamens free; bracts sometimes linear and scariose, sometimes very small or even obsolete. Leaves ovate, acute, or elliptic-lanceolate, the upper ones almost sessile, ochreous. Stem ascending, simple or paniculately branched above. *C. Martensiana*, the only species calling for mention here, thrives in a compost of sandy loam and peat, and may be propagated by divisions of the creeping stem.

C. Martensiana (Martens'). *fl.* white, three-parted; panicle effuse, dichotomous; umbels often compound. *l.* 1¾in. long, ¾in. broad, elliptic-lanceolate, sub-sessile, pubescent beneath. Stems 1ft. to 1½ft. long, branched above. Mexico and Guatemala. Plant exhaling a sweet, Violet-like odour. SYN. *Tradescantia Martensiana* (B. M. 4849).

CALLISTA. A synonym of **Dendrobium** (which *see*).

CALLISTEMON. Including *Metrosideros* (in part). Of the dozen species included in this genus one or two are natives of New Caledonia, and the rest are Australian. To those described on p. 243, Vol. I., the following should be added. One or two formerly included here are now referred to **Kunzea**.

C. lanceolatus (lance-shaped). *fl.* in not very dense spikes 2in. to 4in. long; petals greenish or reddish, ¼in. long; stamens red, 1in. long. June. *l.* lanceolate, 1in. to 3in. long, variable in breadth. *h.* variable. Australia, 1788. SYNS. *C. scaber* (L. B. C. 1283), *Metrosideros citrina* (B. M. 260), *M. lophantha*, *M. semperflorens* (L. B. C. 523).

C. macrostachyum (large-spiked). A synonym of *Kunzea Baxteri*.

C. scaber (rough). A synonym of *C. lanceolatus*.

CALLISTEPHUS. The China Asters show considerable advance. Old favourites like Pæony Perfection, Victoria, Chrysanthemum-Flowered, and Bouquet have been still further improved by the florists, until it looks as if perfection as regards form of flower and compactness of growth had been reached; while several noteworthy additions to the different sections have also been made. The best are:

Comet or **Plume.*** This is a very distinct and beautiful section, characterised by flowers having beautifully-curled petals, reminding one forcibly of Japanese Chrysanthemums. The colour-shades are numerous, and include white, crimson, purple, rose, and soft blues. *h.* from 10in. to 1ft. Then there are the Giant Comets, which attain a height of 15in.

Singles. These have a free and branching habit, pretty, rich foliage, and very large flowers, having but a single row of petals. The best is Sinensis, bearing delicate pale mauve flowers. This is an excellent subject for the mixed border.

CALLITHAUMA. Included under **Stenomesson** (which *see*).

CALLITRIS. *See also* **Widdringtonia.** *C. quadrivalvis* is the Sandarach Gum-tree.

CALLUS. *See also* **Calli,** on p. 242, Vol. I.

CALOBOTRYA. Included under **Ribes** (which *see*).

CALOCEPHALUS (from *kalos*, beautiful, and *kephale*, a head; alluding to the inflorescence). Including *Leucophyta*. ORD. *Compositæ*. A genus embracing about ten species of greenhouse, usually cottony or woolly, annual or perennial herbs, rarely sub-shrubs or small shrubs, natives of Australia. Flower-heads numerous and usually more or less stipitate on a small and branching or globose or conical receptacle, in an ovoid or globular, dense cluster or compound head, without any involucre, or surrounded by a few bracts rarely exceeding the florets; partial heads two- or more-flowered; receptacle without scales; florets five-toothed. Leaves alternate or (in two species) opposite, entire. *C. Brownii* is the only species grown in our gardens. It is much used in carpet-bedding arrangements, and thrives in almost any soil. Propagation may be effected by means of cuttings, inserted under a bell-glass, in a cool greenhouse or frame, and wintered in any light, dry structure, free from frost.

C. Brownii (Brown's). *fl.* in globular clusters four to six lines in diameter, surrounded by a few floral leaves. *l.* alternate, linear, obtuse, two lines or less in length. *h.* 1ft. A rigid, woolly-tomentose shrub. SYN. *Leucophyta Brownii.*

CALOCHORTUS. Wild Tulip of California. SYN. *Cyclobothra*. Baker enumerates twenty-one, and S. Watson thirty-two, species of this genus, natives of North (mostly Western) America, extending as far as Mexico. To those described on p. 245, Vol. I., the following should be added:

C. amœnus (pleasing). *fl.* deep rosy-pink or purple. July. *l.* lanceolate, vigorous. 1892. Intermediate in habit between *C. albus* and *C. pulchellus*. SYN. *Cyclobothra amœna.*

C. apiculatus (apiculate). *fl.* straw-coloured; perianth broadly funnel-shaped, erect, the segments acute, eight to nine lines long. *l.* solitary, flat, linear, 6in. to 12in. long. Stem 1ft. to 1½ft. high, one- to nine-headed. British Columbia.

C. a. minor (lesser). *fl.* cream-coloured, fringed with yellow hairs in the centre.

C. Bonplandianus (Bonpland's). The correct name of *C. purpureus.*

C. citrinus (Citron-coloured). A synonym of *C. Weedii.*

C. clavatus (club-shaped). *fl.* golden-yellow, tinged or lined with brown, large, widely expanded; lower half of the perianth segments covered with strongly clavate hairs; anthers deep purple. Stems much branched. California, 1897. Allied to *C. luteus*. (B. M. 7606.)

C. flavus (yellow). *fl.* yellow, upright; perianth segments rhombic-oblong, acute, the inner ones hairy and usually denticulate, curving outwards, ⅝in. to 1in. long. *l.* below the fork two or three, linear, long-acuminate, 9in. to 12in. long. Stem 1ft. to 2ft. long, slender, often deeply forked, with erecto-patent branches. Oaxaca, &c. Not quite hardy. (B. iv., t. 170.) SYNS. *C. pallidus, Cyclobothra barbata* (S. B. F. G. 273), *Cyclobothra lutea* (B. R. 1663).

C. flexuosus (bending). *fl.* pure lilac; inner perianth segments paler below, slightly hairy or dotted around the brown or orange gland, 1in. to 1¼in. long; bracts linear-lanceolate, ½in. to 1¼in. long. Stem stout, more or less flexuous, branching, not bulbiferous. Southern Utah.

C. Greenei (Rev. E. L. Greene's). *fl.* clear lilac, barred below with yellow and purple, and loosely covered with long hairs; gland densely villous; bracts elongated. June. *l.* 1in. broad, glaucous-green, acute. Stem stout, branching, two- to five-flowered, 1ft. or more in height. California. A handsome species.

C. Gunnisoni Krelaagi (Krelaag's). *fl.* yellow, white, green, and black. California, 1873. A garden variety.

C. Howellii (Howell's). *fl.* creamy-white, very handsome, about 1in. across; inner perianth segments having a dark brown beard on the lower half. Summer. *l.* long, shining. Oregon, 1890. A showy species.

C. Kennedyi (Kennedy's). *fl.* reddish-orange or bright scarlet, not ciliated or hairy, or only slightly so upon a broad, deep purple spot surrounding the densely-hairy gland. July. *l.* linear. Stem two- to four-flowered, usually stout. Southern California, 1892. (B. M. 7264.)

C. longebarbatus (long-bearded). *fl.* one to three, pale purple-lilac, 1¼in. across, with a dark purple stripe across the base of each segment and a beard 1in. long above it. July. Stems 1ft. high. Oregon and Washington, 1890.

C. luteus citrinus (Citron-yellow). *fl.* wholly of a rich lemon-yellow, with a central, circular or tranverse, brownish-purple blotch. (Gn. 1884, p. 437.) SYN. *C. venustus citrinus.*

C. l. concolor (self-coloured). *fl.* of a rich yellow, slightly marked with chestnut-red at the base of the segments. 1895.

Calochortus—*continued.*

A variety of sturdy growth, much branched, and many-flowered. (Gn. 1895, xlviii., t. 1043.)

C. l. Weedii (Weed's). This is regarded by S. Watson as a distinct species.

C. Lyoni (Lyon's). *fl.* pale lilac when opening, but shading to almost white, with dark velvety-brown blotches at the base, large and numerous. Probably California, 1895. One of the earliest-flowering species.

C. madrensis (Sierra Madre). *fl.* bright orange-yellow, with a band of deep orange hairs at the base of each segment, several in a loose head to each stem. August and September. Stem 9in. high at the utmost. North America, 1890. (G. C. 1890, viii., p. 391, f. 78.)

C. Maweanus major (greater). A large-flowered variety.

C. nitidus (shining). *fl.* white or cream-coloured, open-campanulate; outer perianth segments 1¼in. to 1½in. long; inner ones having a lilac or indigo spot in the centre, sparingly hairy below. August. *l.* two or three, narrow-linear, acuminate, ascending, 6in. to 9in. long, three lines broad at base. Stem umbellately one- to three-flowered, 1½ft. to 2ft. high, shortly bracteate in the middle. Oregon, 1826.

FIG. 197. CALOCHORTUS VENUSTUS

C. obispoensis (San Luis Obispo). *fl.*, outer perianth segments orange and purple on a greenish-yellow ground; inner ones lemon-yellow, orange towards the base, tipped with reddish-brown, covered with long, dark hairs, usually cleft at the summit; anthers orange. *l.* narrow, acute, convolute. Stem sparingly branched, 1ft. to 2ft. high. California, 1889. A distinct species. (G. & F. 1889, p. 160, f. 101.)

C. pallidus (pale). A synonym of *C. flavus.*

C. Palmeri (Palmer's). *fl.*, outer perianth segments spotted, recurved at tip; inner ones white (or yellowish below), with a brownish claw and with scattered hairs round the broad, densely hairy gland. Stem very slender, lax and flexuous, 1ft. to 2ft. high, one- to seven-flowered, bulbiferous near the base. California.

C. Plummeræ (Mrs. Plummer's). *fl.* of a very delicate shade of lilac with a satin-like sheen, as much as 4in. across, the inner perianth segments clothed at the base with yellow hairs. *l.* about 2ft. long, broad. Stem strong, branching, many-flowered. California, 1894. A near ally, and possibly a variety, of *C. venustus*. (G. C. 1894, xvi., p. 133, f. 21.)

C. P. aurea (golden). *fl.* golden-yellow, with an irregular, scarlet marking across the segments, and crimson and scarlet dots among the golden hairs. 1897.

C. pulchellus parviflorus (small-flowered). A variety with smaller flowers than in the typical Golden Star Tulip. 1875.

Calochortus—*continued.*

C. Purdyi (Purdy's). *fl.* white, with claret-purple stains at the base and a blotch of the same colour, covered on the inner surface of the segments with silky hairs, which are white, ¼in. long, but deep claret-purple at the base of the segments. *l.* long, linear, bright green, glabrous. *h.* 10in. Habitat not recorded, 1898. A very interesting species.

C. Tolmiei (Tolmie's). *fl.* tubular, tinged or marked with lilac, covered and fringed with purple and white hairs; inner perianth segments ⅔in. to 1¼in. long. Stem stouter and taller than in *C. cæruleus* (to which this species is allied). Oregon.

C. uniflorus (one-flowered). *fl.* pale lilac with a purplish claw, erect, the lower half of the inner perianth segments ⅔in. to 1in. long, hairy above the small, purple, densely hairy gland; peduncle naked, 2in. to 5in. long. *l.* three or four, linear. Stem slender, 3in. to 6in. long, usually one- (but sometimes two-) flowered. California, 1868.

C. uniflorus (of Hooker). A synonym of *C. lilacinus.*

C. venustus. This species and its varieties are still amongst the most attractive of the genus. See Fig. 197.

C. venustus citrinus (Citron-coloured). A synonym of *C. luteus citrinus.*

C. v. oculatus (eyed). *fl.* white, large, each segment marked in the centre with a bright red blotch. 1893.

C. v. pictus (painted). *fl.* white, with rosy spots at the base and a brown blotch on each segment, smaller than in the type. California, 1895.

C. v. roseus (rose-coloured). *fl.* white inside, with a distinct red spot on each segment, purplish-rose outside. *l.* short, bluish-green. 1886. Another variety is *purpurascens* (purplish).

C. Weedii (Weed's). *fl.* deep yellow, dotted and often margined with purple, 1in. or more in length, covered with slender hairs and ciliated; sepals with a slightly hairy, brown spot. Summer. *l.* convolute. Stems leafy, 1ft. high, two- or three-flowered. California, 1875. (G. C. 1894, xvi., p. 183, f. 27.) SYN. *C. citrinus* (B. M. 6200), *C. luteus Weedii.*

CALODENDRON. *Pallasia* (of Houttuyn) is synonymous with this genus.

CALOMERIA. A synonym of **Humea** (which *see*).

CALONNEA. A synonym of **Gaillardia** (which *see*).

CALOPETALON. Included under **Marianthus** (which *see*).

CALOPHACA. About seven species of greenhouse or hardy, perennial herbs, shrubs, or under-shrubs, natives of Asiatic Russia, the Orient, and the Western Provinces of India, are included in this genus. Flowers yellow or violet, few, rather large. Leaves impari-pinnate; leaflets entire, exstipellate.

These plants delight in a mixture of good fibrous loam and leaf-mould. Perfect drainage and an open situation are essential to their successful cultivation. When seeds are procurable they should be sown in heat in spring, and when the seedlings are large enough to handle they should be pricked off into shallow boxes or pans of light soil, and grown on in cold frames until ready for planting out in the open ground. The best time for grafting on stocks of the common Laburnum is in spring before growth commences. Grafting may be done out of doors or under glass. The latter method is the quicker and more certain of the two.

C. grandiflora (large-flowered). *fl.*, calyx five-cleft; corolla golden-yellow, papilionaceous, 1in. long; peduncles axillary and, together with the raceme, exceeding the leaves. June and July. *l.* 2½in. to 8in. long; leaflets ovate, shortly petiolulate, ¼in. to nearly 1in. long, entire. 1886. (R. G. 1231.)

CALOPOGON. SYN. *Cathea.* This genus comprises four closely-related species of hardy, terrestrial Orchids, natives of North America. To those described on p. 246, Vol. I., the following should be added:

C. multiflorus (many-flowered). *fl.* amethyst-purple; stalk of the lip having on each side of the base an auricle, the broad, irregularly square, retuse, emarginate, anterior blade having at the base a tuft of golden-yellow, hairy lamellæ, often purplish at base, and before these some purple calli; peduncle five-flowered. 1884.

CALOSACME. A synonym of **Chirita** (which *see*).

CALOSANTHUS. A synonym of **Oroxylum** (which *see*).

CALOSTEMMA. Only the three species described on p. 247, Vol. I., are referred to this genus, and all are Australian. They should be grown in a compost of sandy loam and leaf-mould, the former preponderating. Propagation is effected by offsets.

C. purpureum (B. R. 422; F. d. S. 1135). Of this there is a variety *carneum*, having pale purple or white flowers, rather larger than in the type. (B. R. 1840, t. 26.)

CALOTHAMNUS. SYN. *Billottia* (of Colla). Twenty-two species, confined to Western Australia, are included in this genus. Flowers in lateral clusters or spikes, usually turned to one side, immersed in the rachis when young, and either protruding and free from the time of flowering, or remaining immersed till the seed becomes mature.

CALPURNIA (named in honour of Titus Julius Calpurnius, an imitator of Virgil; this genus being nearly allied to *Virgilia*). ORD. *Leguminosæ.* A genus comprising about half-a-dozen species of greenhouse trees or shrubs, confined to South Africa. Flowers yellow; calyx shortly five-cleft; standard erect; wings oblong; keel incurved, bifid; stamens ten; racemes axillary and terminal, the peduncles often paniculate. Leaves impari-pinnate, with many leaflets. The species introduced thrive in a compost of peat and loam. Propagation may be effected by means of cuttings of half-ripened shoots, inserted in sand, under a bell-glass, in April; or by seeds, sown on a gentle hot-bed.

C. intrusa (intruded). *fl.* scarcely ¼in. long; calyx intruse at base; peduncles flexuous, much longer than the leaves. May to August. *l.*, leaflets ten to fourteen pairs, glabrescent, elliptical, mucronate. 1790. SYN. *Virgilia intrusa.*

C. lasiogyne (having a silky ovary). Natal Laburnum. *fl.* like those of Laburnum; ovary silky with short, white hairs. *l.*, leaflets four to ten pairs, elliptical, obtuse or retuse, thinly pubescent beneath. 1890.

CALTHA. This genus embraces about nine species, distributed over the temperate and frigid regions of the globe. To those described on p. 247, Vol. I., the following variety should be added:

C. alpina (alpine).* *fl.* of a rich orange-yellow, larger than in *C. palustris* (of which this plant is probably a variety), produced in great profusion. April and May. *l.*, radical ones sub-orbicular or reniform, with crenate margins; cauline ones roundish-cordate, coarsely toothed, sessile. *h.* 1ft. to 1½ft. Transylvania, 1892. A decided acquisition to the bog garden.

C. ficarioides (Ficaria-like). A synonym of *C. palustris parnassifolia.*

CALTHA (of Mœnch). A synonym of **Calendula** (which *see*).

CALVARY CLOVER. *See* **Medicago Echinus.**

CALYCANTHUS PRÆCOX. A synonym of **Chimonanthus fragrans** (which *see*). *Calycanthus fertilis* is identical with *C. glaucus.*

CALYCEREÆ. A small natural order (about a score species) of extra-tropical, South American, dwarf or procumbent herbs, ranking between *Dipsaceæ* and *Compositæ*; they are of botanical interest only.

CALYCIUM. A synonym of **Heterotheca** (which *see*).

CALYCOMIS (of Brown). A synonym of **Callicoma** (which *see*).

CALYCOMIS (of Don). A synonym of **Acrophyllum** (which *see*).

CALYCOPTERIS (from *kalyx, kalykos*, a calyx, and *pteron*, a wing; alluding to the enlarged calyx lobes when the plants are in fruit). SYN. *Getonia.* ORD. *Combretaceæ.* A monotypic genus. The species, *C. floribunda* (SYNS. *C. nutans, Getonia floribunda*), is a diffuse, stove shrub, allied to *Terminalia*, probably no longer in cultivation.

CALYCOSTEMMA. Included under **Isoloma** (which *see*).

CALYCOTHRIX. A synonym of **Calythrix** (which *see*).

CALYCOTOME. A synonym of **Dichilus** (which *see*).

CALYDERMOS (of Ruiz and Pavon). A synonym of **Nicandra** (which *see*).

CALYDOREA (from *kallos*, beautiful, and *dorea*, a gift). SYN. *Botherbe.* ORD. *Irideæ.* A genus embracing about ten species of stove or greenhouse plants, with corm rootstocks, natives of the warmer parts of America. Flowers blue or yellow, very fugitive; perianth segments spreading; stamens inserted at the base of the segments; clusters one or more, pedunculate. Root-leaves terete or narrow-linear. Only one species calls for mention here. For culture, *see* **Glycine.**

C. speciosa (showy). Tahay. *fl.*, perianth-segments blue, yellow at base, obovate-cuneate, 1in. long; spathe 1in. to 2in. long; stems one-headed, 3in. to 9in. long, with two or three reduced leaves. June. *l.*, radical ones narrow-linear, plicate, 3in. to 9in. long. Bulb globose, ¾in. in diameter, edible. Chili, 1836. SYN. *Sisyrinchium speciosum* (B. M. 3544).

CALYMENIA. A synonym of **Oxybaphus** (which *see*).

CALYPLECTUS. A synonym of **Lafoënsia** (which *see*).

CALYPSO. *Cytherea*, *Norna*, and *Orchidium* are synonymous with this monotypic genus.

CALYPTROCALYX. Two species of unarmed, stove Palms, with slender stems, natives of Amboyna and Australia, are included in this genus. Flowers arranged as in *Cyphophœnix*, the males rather large; spadices very long, simple, pendulous, rather thick, long-pedunculate, solitary or twin; spathe solitary, complete, shorter than the spadix, deciduous. Fruit mediocre or rather large, ovoid or olive-shaped, one-celled. Leaves terminal, equally pinnatisect; segments linear-lanceolate, the midrib and nerves prominent beneath.

CALYPTROGYNE. This genus comprises six or eight species, natives of tropical America. Spadices simple or branched from the base, long-pedunculate; spathes two, narrow, the lower one much shorter than the peduncle, cleft at apex, the upper one deciduous, elongated, cleft the whole length. Fruit small, oblong or obovoid, one-seeded. Leaves terminal, unequally pinnatisect; segments in few pairs; petioles very short. To the species described on p. 249, Vol. I., the following should be added:

C. teres (terete). *l.* spreading or drooping, consisting, in young plants, of two pairs of linear-oblong, tapered leaflets about 2in. wide, bright green, with the principal ribs raised; petioles terete. British Guiana. Stove.

CALYPTROON. A synonym of **Baccaurea** (which *see*).

CALYPTROSPERMUM. A synonym of **Menodora** (which *see*).

CALYPTROSTIGMA. A synonym of **Diervilla** (which *see*).

CALYSACCION. A synonym of **Ochrocarpus** (which *see*).

CALYSPHYRUM. A synonym of **Diervilla** (which *see*).

CALYSTEGIA. The seven or eight species of this genus are broadly distributed over temperate and sub-tropical regions. Bracts two, ample, persistent. Leaves alternate entire or rarely palmately lobed. To the species described on p. 249, Vol. I., the following should be added:

C. silvatica (wood-loving). *fl.*, corolla white, showy, campanulate; bracts large, rounded-ovate. July. *l.* cordate-sagittate, sinuate, obtuse, ample, on long petioles. Stems angular, smooth. Hungary, North Africa, &c., 1815. A vigorous and charming twiner for the wild garden. SYN. *Convolvulus sylvaticus.* There is also a pink-flowered form, *incarnata.*

CALYTHRIX. [also spelt *Calytrix*]. SYN. *Calycothrix.* There are thirty-five species of this genus.

C. virgata (twiggy). A synonym of *C. tetragona.* (B. M. 3323.)

CALYTRIX. *See* **Calythrix.**

CALYXHYMENIA. A synonym of **Oxybaphus** (which *see*).

CAMARIDIUM. About a dozen species of stove, epiphytal Orchids, natives of tropical America, are included in this genus. Flowers mediocre, solitary, produced from the axils of the distichous leaves. To the species described on p. 249, Vol. I., the following should be added:

C. Lawrenceanum (Sir Trevor Lawrence's). *fl.*, sepals and petals yellowish-white, the former spotted with reddish-purple, most distinctly on the back; lip deep, dark purple, yellowish-white at apex, ¼in. long; column yellowish-white, with a purple stigma; peduncles axillary, one-flowered. *l.* 1½in. to 3in. long, linear, obtuse. Pseudo-bulbs distant, elliptic-oblong, compressed, two-leaved at apex. Habitat not recorded, 1894.

CAMASSIA. SYN. *Cyanotris.* This genus now embraces five species, all North American. To those described on p. 250, Vol. I., the following should be added:

C. Cusickii (Cusick's). *fl.* pale blue, 1½in. in diameter; perianth segments narrow-oblanceolate, obtuse; raceme long, moderately dense. *l.* glaucous, slightly wavy, 1½ft. to 2ft. long, 1½in. broad. Stem 2ft. to 3ft. high. Bulbs large, clustered. Oregon, 1888. A showy species. (G. & F. 1888, i., 172, 174, f. 32.)

C. Engelmanni (Engelmann's). *fl.* bright blue; perianth segments not so distinctly nerved as in the other species; raceme lax. *l.* 8in. to 12in. long, about 1½in. broad, glaucous above. Bulbs much larger than in the other species. Rocky Mountains, 1889.

CAMBOGIA. A synonym of **Garcinia** (which *see*).

CAMELLIA. Of recent years Camellias have suffered somewhat in popularity. Many have given up their cultivation because of the stiffness or formality of the flowers; but a few novelties, chiefly from Japan, have a distinct and beautiful appearance, being in most instances single or semi-double, and deserving of attention for conservatory decoration or the covering of back walls of cool houses or corridors, for which they are well adapted. Some of the more desirable varieties are as follow:

Singles and Semi-Doubles.—ADELINA PATTI, single petals soft pink, anthers bright yellow; EMIN PASHA, semi-double, petals deep crimson, anthers yellow; GERALD WALLER, not quite double, petals soft carmine, and lightly speckled with a paler shade, anthers yellow; HOTOKE, a charming single white, with deep yellow anthers; LADY ARDILAUN, pure white, with a pretty Anemone-like centre; MRS. LADE, double white, of perfect form; NAGASKI, semi-double, bright carmine petals; TAKAYAMA, petals rich scarlet, a small-flowered, attractive variety; THE DAIMIO, single crimson, with large yellow anthers; THE MIKADO, semi-double, petals crimson, margined with white. The following are also excellent: JAPONICA AITONII, red, large flower; J. ALBA, white, and very floriferous; J. BICOLOR, white, delicately striped with rose; J. CARNESCENS, rose, large flower; J. RUBRA, brick red.

Doubles.—The list of the double-flowering varieties in Vol. I. is so good that it is scarcely necessary to add to their number. It will suffice to mention JUBILEE, flowers of the largest size, with imbricated petals, white, marbled with rose, and SASANQUA ALBA, white, which, unlike most varieties, possesses a fragrance.

CAMELLIA SCALE. *See* **Scale Insects.**

CAMERARIA DUBIA. A synonym of **Wrightia dubia** (which *see*).

CAMPANEA. Includes *Capanea.* This genus embraces six species of softly-villous shrubs, found only in tropical America. Flowers usually pink or white, purple-spotted within, large; calyx broadly campanulate, with five almost leaf-like lobes; corolla tube ample, the limb oblique, with five almost equal lobes; stamens affixed at the base of the corolla, slightly exserted; peduncles axillary, somewhat umbellately many-flowered at apex. Leaves opposite, soft. To the species described on p. 253, Vol. I., the following should be added:

C. Humboldtii (Humboldt's). *fl.* densely tomentose outside, densely spotted within, otherwise as in *C. Oerstedii*; peduncles

Campanea—*continued.*

two- or three-flowered. *l.* obliquely oblong, unequal, long-acuminate, serrated, as much as 9in. long and 3in. broad, densely tomentose above, slightly villous beneath. Stem as in *C. Oerstedii*, but 3ft. long. Costa Rica, 1853. SYN. *Rhytidophyllum Humboldtii.*

C. Oerstedii (Oersted's). *fl.*, calyx villous; corolla greenish, spotted with dark violet, 1½in. long, the tube inflated and curved, the limb 1in. across; peduncles nearly twice as long as the leaves, three- to five-flowered. *l.* obliquely oblong or ovate, slenderly acuminate, serrated, 3in. to 7in. long, 1in. to 2½in. broad; petioles ½in. to 1in. long. Stem 2ft. long, rooting. Costa Rica, 1852. SYN. *Rhytidophyllum Oerstedii.*

CAMPANULA. About 230 species have been referred to this genus; they are broadly dispersed over the Northern hemisphere, being very copious in the Mediterranean region. Calyx tube adnate, the limb deeply five-cleft or five-parted; corolla campanulate, rarely funnel-shaped or sub-rotate, short, five-cleft to the middle or rarely nearly to the base; stamens free of the corolla, the filaments often dilated at base, the anthers free. To the species described on pp. 253-8, Vol. I., the following should be added. A few plants formerly included hereunder are now referred to **Adenophora, Musschia, Platycodon, Prismatocarpus, Specularia, Symphyandra,** and **Wahlenbergia.**

Campanulas, especially the perennial kinds, are some of the most useful of hardy flowers. They have not a wide colour-range, but they make up for this deficiency by furnishing gardens with some of the most beautiful blue shades imaginable. Again, they are most accommodating, and any ordinary border will suit the tall-growing kinds,

FIG. 198. CAMPANULA PERSICÆFOLIA AND WHITE VARIETY.

Campanula—*continued.*

of which the lovely forms of *C. persicæfolia* (Fig. 198), the hybrid *C. Burghalti*, the double-flowered varieties of *C. Trachelium*, the time-honoured Chimney Bellflower (*C. pyramidalis*), and *C. glomerata* are amongst the best.

For the rockery there is a delightful section, embracing the well-known *C. Portenschlagiana*, *C. valdensis*, *C. turbinata*, the pretty trailing *C. isophylla* and *C. i. alba*, and a host of others. The last, together with *C. fragilis*, are favourite subjects for hanging-baskets and for window-plants. Others, like *C. rapunculoides* (a native plant), are worthy of a place in the wild garden.

FIG. 199. CAMPANULA MEDIUM CALYCANTHEMA.

C. abietina (Abies-like). *fl.* light blue; spikes loose, branching. July and August. Stems slender, 9in. to 15in. high. Eastern Europe. Plant tufted.

C. alliariæfolia (Alliaria-leaved). *fl.* creamy-white, nodding, very shortly pedunculate; corolla hairy, infundibular-campanulate, four or five times longer than the calyx. June and July. *l.* pubescent above, hoary beneath; lower ones long-petiolate, ovate-cordate or reniform, crenate-toothed; upper ones much smaller, sessile, ovate. Orient, 1803. SYNS. *C. lamiifolia*, *C. macrophylla* (B. M. 912).

C. autumnalis (autumnal). A synonym of *Platycodon grandiflorum.*

C. Balchiniana (Balchin's). *fl.* of a soft pale blue, 1in. to 1½in. across. *l.* profusely variegated with creamy-white and pale green. 1896. A beautiful hybrid between *C. fragilis* and *C. isophylla alba.*

C. Burghalti (Burghalt's). *See* **C. Van Houttei.**

C. Calycanthema (calyx-flowered). A variety of *C. Medium.*

C. elegans (elegant). *fl.* blue, pendent, shortly pedicellate, disposed in a long, terminal spike; corolla about 1½in. long. June and July. *l.* ovate-lanceolate, acute, sub-triangular, rounded or cordate at base, irregularly toothed; radical ones long-petiolate. *h.* 2½ft. to 3ft. Siberia.

C. garganica hirsuta (hairy). *fl.* very profuse; sepals rather longer and somewhat narrower than in the type; corolla purplish-blue, pale towards the base, saucer-shaped. *l.* (as well as the stem) densely covered with longish, stiff, white hairs. Flowering branches longer and slenderer than in the species. Habit dwarf and more trailing. An excellent plant for hanging baskets, flower-boxes, brackets in corridors, &c.

C. glomerata dahurica (Dahurian). This appears to be merely a dwarf, proliferous form of the species. 1883.

C. Grossekii (Grossek's). *fl.* violet, large, campanulate, disposed in a long raceme. *l.* large, cordate-lanceolate, acuminate, the margins coarsely toothed. Stems leafy, 2½ft. high, branching at base. Eastern Europe, 1886. A handsome plant. (R. G. 1886, p. 477, f. 55.)

C. Hendersoni (Henderson's). A variety of *C. carpathica.*

Campanula—*continued.*

C. Jacobæa (St. James's). *fl.* axillary, on curved pedicels 1½in. to 2½in. long; calyx segments narrow-lanceolate, ½in. to ¾in. long; corolla deep blue or pale greenish, campanulate, 1in. to 1½in. long. March. *l.* 1½in. to 2½in. long, sessile or nearly so, oblong-ovate or obovate-oblong, obtuse or sub-acute, narrowed at base; upper ones cordate, half-amplexicaul. *h.* 2ft. to 3ft. Cape de Verde, 1882. Half-hardy under-shrub. (B. M. 6703.)

C. lamiifolia (Lamium-leaved). A synonym of *C. alliariæfolia.*

C. macrantha (large-flowered). A hybrid form of *C. latifolia.*

C. macrophylla (large-leaved). A synonym of *C. alliariæfolia.*

C. Medium Calycanthema (calyx-flowered). A handsome variety, mainly differing from the type in the greatly enlarged and coloured calyx. See Fig. 199. (A. V. F. 33, 34; R. H. 1889, p. 548.)

C. mirabilis (remarkable). *fl.* pale lilac, large, seven to ten on the branches; corolla campanulate. August and September. *l.* coriaceous, irregularly crenulate-toothed; radical and lower ones elongated-ovate. Root napiform. Abchasia, 1895. A pretty alpine. (G. C. 1898, ii., p. 33, f. 10; R. H. 1895, p. 477.) SYN. *C. regina.*

C. olympica (Olympian). *fl.* pale blue, very shortly pedunculate, solitary or racemose; calyx segments spreading or reflexed; corolla obconical-funnel-shaped, cut into acute lobes. Summer. *l.*, radical ones obovate, petiolate, obtuse, with a few crenatures; middle ones linear, oblong, semi-amplexicaul; upper ones lanceolate, acute. Orient. Biennial.

C. pentagonia (five-angled). A synonym of *Specularia pentagonia.*

C. persicæfolia maxima (largest). A very large variety.

C. prenanthoides (Prenanthes-like). *fl.* blue, racemose; corolla twice the length of the slender calyx-lobes and almost five-parted. *l.* about ½in. long, ovate-oblong to lanceolate, sharply serrated; cauline ones mostly sessile. Stems 1ft. to 2ft. high. Rocky Mountains, 1873. SYN. *C. Roezli.*

C. regina (queen). A synonym of *C. mirabilis.*

C. Roezli (Roezl's). A synonym of *C. prenanthoides.*

C. saxifraga (stone-breaker). *fl.* violet, ¾in. to 1in. long; calyx segments oblong-lanceolate. *l.* linear or linear-lanceolate, narrowed to a petiole, entire or crenate from the middle; cauline ones linear, entire. Stems 3in. to 6in. high. Caucasus, 1875. SYN. *C. tridentata saxifraga* (of gardens).

C. serpyllifolia (Serpyllum-leaved). *fl.* blue, sessile; calyx tube ovoid, the lobes obtuse, ciliated. *l.* oblong-lanceolate, obtuse or retuse, ciliated; radical ones clustered, petiolate; cauline ones few, alternate, sessile. Stems tufted, diffuse, procumbent, one-flowered. Dalmatia, &c., 1889. SYN. *Edraianthus serpyllifolius.*

C. sibirica eximia (choice). *fl.* varying from pale bluish to violet, narrow-campanulate; stem much branched. *l.* long, scabrous. Europe, &c., 1883. Habit dwarf and compact.

C. strigosa (bristly). *fl.* purple, shortly pedunculate, variable in size; corolla glabrous. July and August. *l.* sessile, entire; lower ones oblong; upper ones oblong-lanceolate, acute. Stems erect, dichotomously and somewhat divaricately branched. *h.* 1ft. to 2ft. Syria, &c., 1819. Half-hardy annual. (B. M. 5068.)

C. stylosa (long-styled). A synonym of *Adenophora stylosa.*

C. Tenorei (Tenore's). A form of *C. versicolor.*

C. tridentata saxifraga (three-toothed stone-breaker). A garden synonym of *C. saxifraga.*

C. turbinata (top-shaped). A variety of *C. carpathica.*

C. versicolor Tenorei (Tenore's). A neat variety, not exceeding 1ft. in height.

C. Zoysii (Zoys').* *fl.* of a clear blue; corolla long-tubular, with five short, triangular lobes. *l.*, radical ones rosulate; cauline ones linnear: Austrian Alps, 1896. A charming alpine. (G. C. 1896, ii., p. 182, f. 32.)

CAMPANUMÆA. Some five or six species, natives of the Himalayas, Malaya, Southern China, and Japan, are included in this genus.

C. gracilis. This now forms a genus by itself. *See* **Leptocodon.**

C. lanceolata (lanceolate). A synonym of *Codonopsis lanceolata.*

CAMPELEPIS. A synonym of **Periploca** (which *see*).

CAMPELIA (from *kampe*, bending, and *helios*, the sun; the flowers bend round towards the sun). SYNS. *Gonatandra, Zanonia.* ORD. *Commelinaceæ.* A monotypic genus. The species, *C. Zanonia*, is a robust, stove perennial, broadly dispersed over tropical America; it has been introduced, but is probably lost to cultivation.

CAMPELIA (of Link). A synonym of **Deschampsia** (which *see*).

CAMPION. *See* **Silene.**

CAMPION, MOSS. *See* **Silene acaulis.**

CAMPOMANESIA (commemorative of Campomanes, a Spanish naturalist). ORD. *Myrtaceæ.* A large genus (nearly 100 species) of stove or greenhouse trees or shrubs, with the habit of *Psidium*, natives of tropical and subtropical America. *C. lineatifolia*, a Peruvian species, has been introduced, but is probably no longer in cultivation.

CAMPSIDIUM [not *Capsidium*]. This genus is included, by Bentham and Hooker, under **Tecoma** (which *see*), and the correct name of *C. chilense* is *T. valdiviana.*

CAMPTOCARPUS. A synonym of **Alkanna** (which *see*).

CAMPTOSEMA (from *kamptos*, curved, and *sema*, standard; in allusion to the curved appendage on both sides of the base of the standard). SYN. *Bionia.* ORD. *Leguminosæ.* A genus embracing ten species of sub-erect or twining, stove or greenhouse shrubs or under-shrubs, confined to South America. Flowers scarlet, showy, fasciculate-racemose towards the apex of the axillary peduncles; standard ovate or oblong; wings oblong; keel oblong, nearly straight. Leaves pinnately trifoliolate, rarely with only one or five to seven leaflets; stipules deciduous. The three species introduced thrive in a compost of sandy loam and leaf-soil, and may be increased by cuttings or by seeds.

C. pinnatum (pinnate). *fl.* 2in. long, in a short, stout raceme; petals of a pale but bright red-purple, straight, narrow, obtuse. July. *l.* 1ft. to 1½ft. long, alternate, shortly petiolate; leaflets three pairs and a terminal one, shortly petiolulate, drooping, 6in. to 7in. long, 2in. to 3in. broad, oblong or ovate-oblong, obtusely caudate-acuminate. *h.* 3ft. to 5ft. Brazil, 1838. Stove. (B. M. 7582.)

C. rubicundum (reddish). *fl.* deep ruby-red; standard partly reflexed, clawed; racemes compound, 8in. to 10in. long, drooping, many-flowered. *l.* distant, long-petiolate, trifoliolate; leaflets oblong or oblong-elliptic, glaucous beneath. Stem as thick as a finger. Southern Brazil. A very handsome climbing, stove shrub, of great length. (B. M. 4608.)

C. splendens (splendid). *fl.* produced in threes, on short and rough pedicels; calyx pale brown; corolla of a rich, bright crimson; racemes axillary, terminal. October. *l.* ternate; leaflets oblong-lanceolate, obtuse, smooth, dull green. Brazil (?). Greenhouse climber. SYN. *Kennedya splendens* (P. M. B. iii., p. 26).

CAMPYDORUM. A synonym of **Polygonatum** (which *see*).

CAMPYLANTHERA ELEGANS. A synonym of **Marianthus cœruleo-punctatus** (which *see*).

CAMPYLANTHUS (from *kampylos*, a curve, and *anthos*, a flower; in allusion to the incurved corolla-tube). ORD. *Scrophularineæ.* A small genus (four species) of greenhouse shrubs, natives of the Canary and Cape de Verde Islands, Arabia, and Scinde. Flowers racemose at the tips of the branches, often secund; calyx deeply five-cleft or five-parted; corolla-tube elongated, incurved, the limb of five spreading lobes. Leaves alternate, linear, somewhat fleshy, entire. *C. salsoloides* has been introduced, but is probably lost to cultivation.

CAMPYLOCENTRON SCHIEDEI. The correct name of **Todaroa micrantha** (which *see*).

CANALA. A synonym of **Spigelia** (which *see*).

CANARIA. *See* **Canarina.**

CANARIUM. SYN. *Colophonia.* This genus embraces about fifty species, mostly natives of tropical Asia; a few are indigenous in Africa and the Mascarene Islands, and one is found in Australia. To the species described on p. 259, Vol. I., the following should be added:

C. vitiense (Fijian). *fl.* yellowish-white, small, paniculate. *fr.* bluish-black. *l.* pinnate; leaflets five to seven, oblong-elliptic, obtuse. Fiji, 1887. A small tree.

C. zeylanicum (Cingalese). The correct name of *Balsamodendron zeylanicum.*

CANARY CREEPER. *See* **Tropæolum peregrinum.**

CANARY GRASS. *See* **Phalaris canariensis.**

CANAVALI. *See* **Canavalia.**

CANAVALIA. To the species described on p. 259, Vol. I., the following should be added:

C. Lunareti (Lunaret's). *fl.* of a beautiful rose-pink, large. Summer. *fr.* about 6in. long, strongly mucronate at apex. *l.* trifoliolate; leaflets glabrous, 5in. to 6in. long, 2½in. broad, ovate, narrowed to an acute apex. Japan, 1881. (R. H. 1881, f. 56-57.)

CANCERWORT. *See* **Veronica.**

CANDOLLEA (of Labillardière), in part. A synonym of **Stylidium** (which *see*).

CANDY CARROT. *See* **Athamanta Matthioli.**

CANE. A term applied to the stems of Reeds and the larger Grasses, to one-year-old stems of Grape Vines, and to the stems of Blackberries and Raspberries.

CANELLA. SYN. *Winterana.* There are only two species of this genus, one being a native of the West Indies and the other of Venezuela. Bracts three; sepals five; petals wanting; cymes in terminal, almost corymbose panicles.

CANISTRUM. This genus is included by J. G. Baker under **Æchmea** (which *see*), the plants described on p. 260, Vol. I., retaining their specific names.

CANKER is a little understood disease affecting Apple, Pear, and other trees, but chiefly Ash, Lime, Maple, and Hazel. The term in the past has been rather loosely applied, and the condition of the bark usually known as Canker has been ascribed to many causes. Even now there are numbers who will not admit that the disease is of fungus origin, but prefer to think that it is due entirely to errors in cultivation rather than to the ravages of the Wound Fungus, *Nectria ditissima*. That certain conditions of soil predispose trees to the attack of the fungus is doubtless correct; but the real trouble is due to the fungus above-named finding a lodgment in cracks of shrunken bark, in wounds caused by hail, frost, insect punctures, the careless use of the pruning-knife, etc.

Once the bark is attacked the wood soon becomes involved, and if preventive measures are not taken the trees may be killed outright. Amongst predisposing causes may be mentioned damp, cold, undrained soils. Again, certain varieties are more prone to Canker than are others, some of the best dessert Apples, like Blenheim Pippin, Cox's Orange Pippin, and Ribstone Pippin being amongst those most susceptible.

As stated above, the fungus, as a rule, enters through a wound in the bark, and it spreads rapidly to the parts adjoining the wood. It may manifest itself first in some of the smaller branches, when there is usually a dying away of the shoots in the vicinity; or it may be first seen on the trunk itself. There is considerable cracking of the bark (see Fig. 200, A); and if such cracks are carefully examined in spring there will be found groups of deep red dots. These are known as perithecia (Fig. 200, B), and they contain spore-bearing asci. In the autumn previous there was another form of fruit developed known as conidia, and borne upon white cushions. It is these spores which give rise to the disease once they find a suitable nidus.

A visit to the average country orchard will reveal numbers of these Cankered trees, old and unfruitful. Not only, too, may the branches be cracked in the way already suggested, but the main trunk may have its bark so distorted as to present the appearance shown at Fig. 201, in which the discoloured affected wood is disclosed.

Directly Canker is noted all diseased shoots should be cut away and burned. Portions of stems affected should

Canker—*continued.*

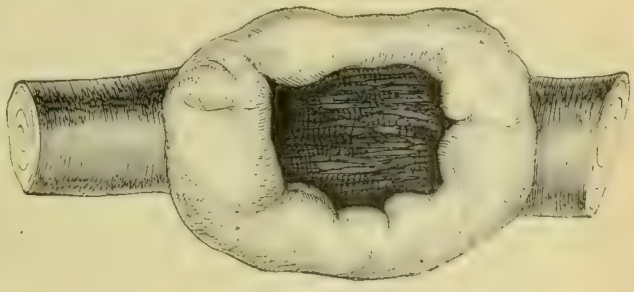
FIG. 200. CANKER DUE TO NECTRIA DITISSIMA.

A, showing piece of Apple tree affected. B, Perithecia, showing orifices from which spores escape.



By permission of the Board of Agriculture.

FIG. 201. DISTORTED BARK DUE TO CANKER.

Canker—*continued.*

also be cut out and similarly treated, afterwards dressing the part with Stockholm tar. In the case of old and unfruitful trees badly attacked, these should be uprooted and burned.

In the United States there is a very destructive disease of Apples and Pears, sometimes spoken of as Canker. This is of bacterial origin, and has been referred to under Apple and Pear Blight (*Micrococcus amylovorus*). This attacks the main trunk as well as the smaller branches; even the blossoms are affected, and turn black. Roses are also affected by Canker due to a fungus.

CANKER WORM. A name applied by Americans to the caterpillars of certain destructive moths affecting Apple trees. One is a near relative of the March Moth (*Anisopteryx æscularia*), which gives trouble in this country, and should be similarly treated. The other is *Paleacrita vernata*. The former appears in autumn; the latter in spring.

CANNA. Nearly ninety specific names are kept up in the "Index Kewensis," but, according to Mr. J. G. Baker ("Gardeners' Chronicle," 1893), a large majority of these probably represent garden forms. "In this genus the short outer wrapper of the flower—the three small green leaves that remain on the top of the capsule—represents the calyx. The corolla is represented by the three longer equal leaves, of firmish texture and greenish colour, that form the next row. The showy part of the flower consists of the stamens, which are brightly coloured and put on the appearance of ordinary petals. These petaloid staminodia are unequal in size, and to the margin of one of the inner ones the one-celled anther is attached." All the species are natives of tropical or sub-tropical America.

The new race of Large-flowered Cannas, which the florist has evolved by skilful hybridising, marks an epoch in this flower. Alike in flowers and foliage, the new Cannas quite outstrip the old; they combine, in fact, the gorgeousness of the finest Gladioli with the beauty of the Dracæna. They may be used with telling effect in the borders in summer, on lawns, or in beds. Indoors they are quite as useful, and their season of beauty is a long one. They may be planted outside in late spring, affording them good rich soil and a sheltered position. They may be left out in the more favoured soils, and in the South and West of England, if covered with litter in severe weather; otherwise, they are best lifted and stored out of the reach of frost. For indoor work, they may be potted in either spring or autumn. Wherever grown, they like plenty of moisture in the growing season. They are propagated by seeds, or by dividing the crowns in spring into pieces containing from two to three growths.

To those described on p. 262, Vol. I., the following should be added:

C. esculenta (esculent). A synonym of *C. edulis*, from the rootstock of which is procured Canna Starch ("Tous les Mois").

C. grandiflora picta (large-flowered, painted). *fl.* yellow, spotted with red. 1885. A handsome and robust, garden variety. (R. H. 1885, p. 396.)

C. indica Bertini (Bertin's). *fl.* dark crimson, very large, borne in a spike-like panicle. *l.* narrow-ovate, of a beautiful pale green. *h.* 2ft. to 2½ft. 1889. A garden variety of the Indian Reed.

C. L. variegata (variegated). *l.* striped with yellow. Solomon Islands, 1897.

C. lanuginosa (woolly). The correct name of *C. Achiras*.

C. latifolia (broad-leaved). The correct name of *C. gigantea* (B. M. 2316).

C. liliiflora (Lily-flowered). *fl.* 4in. to 5in. long, Honeysuckle-scented, in a short, terminal raceme; perianth tubular, the three outer petaloid lobes linear-oblong, convolute, reflexed, tinged green, the three inner ones straight and extended, recurved at end, white, tinted yellowish-green. *l.* large, Musa-like, oblong, acuminate. Stems stout, erect. *h.* 6ft. to 10ft. A fine plant. (F. d. S. 1055-6; R. H. 1884, 132.)

C. lutea aurantiaca (orange-yellow). The correct name of *C. aurantiaca*.

Canna—*continued.*

C. patens limbata (spreading, bordered). The correct name of *C. limbata*.

C. Reevesii (Reeves'). A synonym of *C. flaccida*. (B. R. 2004.)

C. rosæflora (rose-flowered). *fl.* magenta-red. 1885. Garden variety. (R. H. 1885, p. 396.)

Varieties. Some of the best are as follow:

A. DE MONTEBELLO, flowers carmine, shaded with orange; leaves bright green and distinct; good for outdoor culture. AIGRETTE, flowers scarlet with a thin margin of gold, large; leaves deep green; 3ft. to 4ft. ALPHONSE BOUVIER, flowers dark crimson, of fine form, spikes large and freely produced; leaves bronzy-green, erect; 3ft.; one of the best for either indoor or outdoor culture. AMERICAN FLAG, flowers orange-scarlet with a well-marked gold band on the margin of each petal; large and of good form; best adapted to indoor culture. AMI JULES CHRETIEN, flowers chestnut-red, very large, and of great substance; leaves green and massive; 3ft. AMI PICHON, flowers rich scarlet, of fine globular form, and very free; leaves green; 3ft. to 4ft. AMIRAL AVELLAN: there are two distinct varieties known under this name, the one sent out by Vilmorin and Co. has bright yellow flowers spotted with red, and green leaves. The other, sent out by Crozy, has carmine-red flowers, with dark bronzy leaves. Both are handsome varieties. ANTOINE CHANTIN*, flowers very large, deep cerise salmon; leaves dark green; remarkably floriferous and dwarf; one of the best. ANTONIN CROZY, flowers rich crimson, large spikes; leaves dark green, marked with purple; 3ft. to 5ft. AURORE, flowers deep orange-red, very large and of good form; leaves deep green 3ft. to 4ft. AUSTRIA*, flowers canary-yellow, spotted with brown, very large, and of grand form; leaves green, long, handsome; 4ft. to 6ft. BEAUTÉ FOITEVINE, flowers bright red, large; leaves glaucous green; 3ft. CAPITAINE P. DE SUZZONI, flowers bright yellow, slightly spotted, large; leaves pale green; 3ft. to 5ft. COLIBRI*, flowers clear yellow, with deep carmine centre; leaves green; 3ft.; a distinct variety. COMTE DE BOUCHAUD*, flowers golden-yellow, heavily spotted with bright red; leaves deep green; 3ft.; a very handsome variety. COMTE DE GANAY, flowers a lovely salmon shade margined with yellow, large and fine; leaves deep green; 3ft. to 4ft. CRIMSON KING, flowers intense crimson, splendid spikes; leaves bronzy-green; 3ft. DUCHESS OF YORK*, flowers yellow, heavily spotted with red, large, good form, and free; leaves deep green; 3ft. DUKE OF YORK*, flowers vermilion-red, margined with yellow; leaves green; 4ft.; very free. FLORENCE VAUGHAN, flowers bright yellow, heavily spotted with scarlet; 3ft.; see Fig. 202. FREDERIC BENARY, flowers crimson-red; leaves green and long; 4ft. F. THOMAYER, flowers bright orange, very large and fine; leaves purple; 3ft. to 4ft. GEOFFREY SAINT-HILAIRE*, flowers

Canna—*continued.*

deep orange; leaves dark bronze; 4ft.; free and very fine. GERMANIA, flowers deep crimson, margined with clear yellow; leaves bold and massive; 4ft. HENRY IRVING, flowers fine orange-scarlet, lower half of petal deep yellow; 3ft. ITALIA*, flowers scarlet and yellow, 5in. across, freely produced; leaves deep green; 5ft. to 7ft. JULES CHRETIEN*, flowers crimson, large; leaves dark green; 4ft.; a fine variety. KONIGEN CHARLOTTE*, flowers deep red, with a broad margin of gold; leaves dark green; 2ft. to 3ft.; a splendid variety for indoor culture. NIAD CROZY, flowers orange-vermilion, large, and fine; leaves green; 3ft. PAUL BRET*, flowers clear amber; leaves bronzy-purple; 2ft. to 3ft.; distinct and good. PAUL BRUANT, flowers orange-red, large, fine spikes; leaves green; 4ft. PRESIDENT

FIG. 203. CANNA PRESIDENT CARNOT.

CARNOT*, flowers red, large; leaves bronzy-green; 4ft.; see Fig. 203. QUASIMODO, flowers vermilion, margined with yellow; leaves green; 3ft. to 4ft. SENATEUR MILLAUD, flowers deep orange; leaves very dark; 4ft.; an effective variety. SIMON DELAUSE*, flowers golden-yellow, heavily spotted vermilion; leaves green; 4ft.; very fine. SOUVENIR D'ANTOINE CROZY*, a more vigorous and improved form of NIAD CROZY. SOUVENIR DE JEANNE CHARRETON, flowers bright orange-red, large; leaves dark green; 4ft. ULRICH BRUNNER*, flowers deep red, large, fine form; leaves green; 4ft. to 5ft.; a splendid variety.

CANNIBAL'S TOMATO. *See* **Solanum Anthropophagorum.**

CANSCORA. SYN. *Codamba.* This genus embraces about a dozen species, natives of tropical Africa, the East Indies, the Malayan Archipelago, and tropical Australia.

CANTHIUM. The following synonyms should be noted under this name:

C. chinense (Chinese). A synonym of *Randia dumetorum.*

C. coronatum (crowned). A synonym of *Randia dumetorum.*

CAPANEA. Included under **Campanea** (which *see*).

CAPE FIGWORT. *See* **Phygelius capensis.**

CAPE GUM-TREE. *See* **Widdringtonia juniperoides.**

CAPE HONEY FLOWER. *See* **Protea mellifera.**

CAPE PHILLYREA. *See* **Elæodendron capense.**

CAPE POISON BULB. *See* **Buphane disticha.**

CAPE PRIMROSE. *See* **Streptocarpus.**

CAPIA. A synonym of **Lapageria** (which *see*).

CAPNODIUM. *See* **Honeydew.**

CAPNODIUM QUERCINUM. *See* **Oak Fungi.**

CAPNORCHIS. A synonym of **Dicentra** (which *see*).

CAPOLLIN, CAPOULINOS. These names are applied to the fruits of *Cerasus Capuli* and *Prunus salicifolia.*

CAPPARIS HETEROCLITA. A synonym of **Mærua oblongifolia** (which *see*).

CAPRARIA RIGIDA. A synonym of **Freylinia undulata** (which *see*).

CAPREOLATE. Furnished with tendrils.

CAPRIFICATION. A supposed method of assisting in the production of figs by means of insect agency. *See* **Fig Insects.**

CAPROXYLON. A synonym of **Hedwigia** (which *see*).

CAPSICUM. Additional varieties are Golden Dawn, Ruby King, and Bell-shaped. In Gloucestershire, a very large variety, Bull's Nose, is grown; it is mild in flavour, and much esteemed by cooks.

Capsicums, although such hot subjects, are liable to insect pests of various kinds. To eradicate these, XL All Vaporiser will prove most effectual, without any detriment to the plant.

CAPULINOS. *See* **Capollin.**

CARABIDÆ. *See* **Beetles.**

CARAGANA. This genus embraces about fifteen species, natives of Asiatic Russia and the Himalayas. To those described on pp. 264-5, Vol. I., the following variety should be added:

C. arborescens pendula (pendulous). This only differs from the type in having the branches pendulous. 1887.

C. pendula (pendulous). A variety of *C. arborescens.*

CARAGUATA. *Massangea* and *Schlumbergia* are included here by J. G. Baker. The species number nearly two score, and are found in the West Indies, Guiana, and the Andes. Flowers clustered; sepals erect, imbricated, shortly connate at the base; corolla gamopetalous, the oblong segments shorter than the cylindrical tube; stamens inserted at the throat of the corolla-tube; filaments short; anthers free. Leaves and habit as in *Tillandsia* (from which this genus differs only in its gamopetalous corolla). To the species described on p. 265, Vol. I., the following should be added:

C. Andreana (André's). *fl.* about 2in. long, numerous; calyx and corolla bright yellow; panicle spike-like, rather lax, longer than the leaves; stem and bracts carmine-rose. March. *l.* arching, green, 2ft. long, 2in. broad, forming a lax rosette Andes of Pasto, 1884. (B. M. 7014; R. H. 1884, p. 247, f. 61 1886, p. 276.)

C. angustifolia (narrow-leaved). *fl.* large, few in a dense spike; calyx whitish, the segments oblong, acute; corolla yellow, the tube cylindrical, 2in. long; bracts red, large, oblong-lanceolate; peduncle short, with a few reduced leaves. *l.* in a dense rosette, 6in. long, lanceolate, channelled from the ovate base to the attenuated apex. Andes of Colombia, 1884. SYN. *Guzmania Bulliana.*

Caraguata—*continued.*

C. Belcana (Dr. Le Bèle's). *fl.* white, disposed in a compound, divaricate panicle; corolla about 2in. long; peduncle about 2ft. high. *l.* circinate, 2ft. to 2½ft. long, bright green, acuminate, dilated at base, lepidote on the under-surface. Origin unknown, 1891. (R. H. 1891, p. 114, f. 27.)

C. cardinalis (scarlet). A variety of *C. lingulata.*

C. conifera (cone-bearing). *fl.*, corolla pale yellow, above 2in. long, just overtopping the bright scarlet bracts; head dense, conical, 8in to 10in. long; peduncle erect. *l.* lanceolate, acute, bright green, 2ft. to 3ft. long, 2½in. to 3in. broad, forming a dense rosette. Ecuador, 1894. (B. M. 7359.)

C. Devansayana (Devansay's). The correct name of *Guzmania Devansayana.*

C. Fuerstenbergiana (Fuerstenberg's). *fl.*, corolla whitish, 1½in. long; spike simple, multifarious, 2in. to 3in. long, the bracts bright red. July. *l.* about fifteen in a rosette, lanceolate, 12in. to 16in. long. Andes of Ecuador, 1883.

C. Lindeni. The correct name of *Massangea Lindeni.* SYN. *Schlumbergeria Lindeni* (B. H. 1883, p. 121, tt. 10-12).

C. lingulata. The following are varieties of this species, with larger and more brightly-coloured outer bracts than the type: *C. splendens* (F. d. S. 1091), *C. cardinalis* (I. H. 1830, t. 674).

C. magnifica (magnificent). *fl.*, corolla yellow, ¼in. longer than the calyx; panicle 1½ft. to 2ft. long, many-branched; bracts reddish-yellow, 1½in. long. *l.* thirty in a rosette, pliable, lanceolate, above 1ft. long, 1½in. to 2in. broad, tinged with claret-brown. A garden hybrid between *C. Zahnii* and some robust *Tillandsia.*

C. magnifica (magnificent, of gardens). A synonym of *C. Osyana.*

C. Melinonis (M. Melinon's). *fl.*, corolla yellow, 1¼in. long; inflorescence a dense, simple, oblong spike, 3in. long; peduncle shorter than the leaves; bracts red. *l.* densely rosulate, 1ft. long, 1½in. to 2in. broad, lorate, tinged with brown beneath. French Guiana, 1879. SYN. *Guzmania Melinoki.*

C. Morreniana (Morren's). *fl.* yellow, in a large, compact head; bracts bright red; flower-stem 4in. to 6in. long *l.* rosulate, 16in. to 20in. long, 2in. broad, with recurved, acuminate tips; outer ones dark green, gradually passing, by being shaded and tinted with violet, into the violaceous floral ones. Rio Cuiaquer, Colombia, 1887. (R. H. 1887, p. 12.)

C. musaica (mosaic). (B. M. 6675; I. H. 1877, t. 268.) The correct name, according to Baker's classification, of the plant described by Morren under name of **Massangea musaica** (which *see*, on p. 335, Vol. II.).

C. Osyana (Baron Edouard Osy's). *fl.* axillary, solitary, shorter than the bracts; corolla yellow, twice as long as the calyx, clavate-tubular, sub-arcuate, the tube elongated, the lobes erect; bracts orange-salmon, imbricated, reflexed; spike compact, strobiliform. *l.* coriaceous, 1½ft. long, lanceolate, somewhat channelled. Stem erect, short, robust. Ecuador, 1885. (B. H. 1885, p. 254, tt. 16-17.) SYN. *C. magnifica* (of gardens).

C. Peacockii (Peacock's). *fl.* white, densely spicate; stem covered with bright purple bracts, the upper ones rolled round the flowers. *l.* 1ft. long, bronzy-purple above, rosy-purple beneath, forming an ample rosette. Probably Andine, 1835.

C. sanguinea (blood-coloured).* *fl.* clustered at the base of the centre of the rosette of leaves; corolla 2½in. to 3in. long, the tube yellowish-white, long, clavate, the three segments white, ovate. November. *l.* in a dense rosette, lanceolate, acute, falcate, thin, the lower part green, the upper half or two-thirds strongly tinged with bright red on both sides, the outer leaves 1ft. or more in length. Colombia, 1880. Plant stemless. (B. M. 6765; R. H. 1893, p. 468.)

C. Schlumbergerii (Schlumberger's). The correct name of *Schlumbergeria Morreniana.* SYN. *Massangea Morreniana* (of gardens).

C. serrata (saw-toothed). A garden synonym of *Karatas Scheremetiewii.*

C. splendens (splendid). A variety of *C. lingulata.*

C. straminea (straw-like). The correct name of *Schlumbergeria Morreniana.*

C. virescens (greenish). (B. H. 1879, p. 360, t. 19.) The correct name of *Schlumbergeria Roezlii, Pitcairnia virescens,* and *Puya virescens* (B. M. 4991)

CARALLIA. SYNS. *Diatoma, Petalotoma, Symmetria.* Seven species are included in this genus; but *C. lanceæfolia* and *C. lucida* are the only ones that have been introduced, and probably they are now lost to cultivation.

CARALLUMA. This genus includes about half-a-dozen species, natives of India and Arabia. To those described on p. 265, Vol. I., the following should be added:

C. campanulata (campanulate). *fl.* disposed in a terminal umbel; corolla reddish-brown, velvety, star-shaped, the limb 1in. across, flat. July. Branches ascending, four-angled, pale green, about

Caralluma—*continued.*

⅜in. in diameter. Ceylon, 1890. (B. M. 7274; G. C. 1892, xii., p. 369, f. 61.)

C. Luntii (Lunt's). *fl.* yellowish-green, spotted with purple, 1in. in diameter, five-lobed. Stems quadrangular, smooth, 8in. high, ¾in. thick, conspicuously toothed, marbled with purple. Southern Arabia, 1894.

CARANDAS. *See* **Carissa Carandas.**

CARAPICHEA. A synonym of **Cephaelis** (which *see*).

CARBENIA (compounded of the first syllables of *Carduus benedictus*, on which plant the genus was founded). SYN. *Cnicus* (of Gærtner). ORD. *Compositæ.* A monotypic genus. The species is a handsome, dwarf, hirsute or pubescent, annual herb, admirably adapted for the shrubbery, and thriving in any ordinary soil.

C. benedicta. Blessed Thistle. *fl.-heads* pale yellow, sessile, 1½in. high; involucral bracts in few ranks, abruptly tipped with an aristiform or spinescent and pectinately prickly appendage. *l.* blotched and marbled with silvery-white, sinuately pinnatifid or laciniate-toothed, the teeth or margins weakly prickly. South Europe and North-west America. SYNS. *Centaurea benedicta, Cnicus benedictus.*

CARBONATE OF LIME. Chalk, shell-sand, and marls are all forms of Carbonate of Lime. The marls also contain a certain proportion of potash and of phosphoric acid. These forms of Lime added to lands deficient in this substance have proved of great value: they are capable of neutralising the organic acids contained in sour soils, and form a valuable plant-food for many garden crops; they exert a decided beneficial mechanical influence upon stiff soils, besides consolidating light, sandy soils, liberating the potash, and forming the valuable double silicates. Marls are particularly useful in the cultivation of Roses.

CARDAMINE. *Dentaria* (see Vol. I., p. 458) and *Pteroneurum* (see Vol. III., p. 246) are included here by Bentham and Hooker. As many as sixty species, inhabiting the temperate and cold regions, are referred to this genus.

CARDAMOMUM. A synonym of **Elettaria** (which *see*).

CARDIOLOPHUS. A synonym of **Herpestis** (which *see*).

CARDIOSPERMUM (from *cardia*, the heart, and *sperma*, a seed; in allusion to the prominent, white, heart-shaped scars on the seed, which indicate its point of attachment). ORD. *Sapindaceæ.* A genus embracing upwards of a dozen species of climbing shrubs or herbs, natives of tropical and temperate regions. *C. Halicacabum* (Heartseed or Heart Pea) is largely used medicinally, and its leaves as a vegetable by the natives. The species have no horticultural value.

CARDOPATIUM (from *kardia*, a heart, and *pathos*, suffering; formally employed medicinally in cases of heart disease). SYN. *Brotera.* ORD. *Compositæ.* A small genus (two species) of half-hardy, perennial, Thistle-like herbs; one is a native of North-west Africa and the other is found in the Orient. Flower-heads blue, very numerous, subsessile, disposed in a dense, leafy, very spiny corymb; florets equal; involucre ovoid-oblong, with the bracts in many series; receptacle small, densely bristly; pappus paleæ numerous, in one or two series. Leaves alternate, once or twice pinnatisect, the lobes spiny. *C. corymbosum* is a useful plant for associating with tall subjects or for placing at the back of borders in ordinary soil, and only requires protection from frost. Propagated by division.

C. corymbosum (corymbose). *fl.-heads* ovate-conical; florets eight to ten. *l.*, radical ones oblong, pinnately parted; cauline ones narrower, gradually diminishing. Stems di- or trichotomously-branched, densely corymbose. *h.* 1ft. Greece, &c., 1871. (R. G. 692.) SYN. *Carthamus corymbosus* (S. F. G. 844).

CARDUNCELLUS. SYN. *Onobroma* (of Gærtner). About fourteen species, mostly natives of the Mediterranean region, are included in this genus. Leaves alternate, spiny-toothed or lobed.

CARDUUS. The proper name of *Cnicus benedictus* (mentioned under this heading on p. 266, Vol. I.) is **Carbenia benedicta** (which *see*).

CARELIA (of Adanson). A synonym of **Ageratum** (which *see*).

CAREX. Upwards of 800 species have been referred to this genus, but probably not more than 500 are entitled to rank as such; they are copiously dispersed over temperate and frigid regions, but few being found within the tropics, and those on mountains. To those described on p. 267, Vol. I., the following should be added:

C. arenaria (sand-loving). *fl.*, spikelets rather large, ovoid, all simple and sessile, usually crowded eight or ten together in a terminal spike of 1in. to 2in. Summer. Rootstock creeping, often many feet, emitting small tufts or single stems from a few inches to 1½ft. in height and leafy at base. Europe (Britain), in maritime sands.

C. brunnea (brown). *fl.*, inflorescence long, lax; peduncles often several from each sheath, the lowest exserted 1in. to 8in., slender, nodding, sometimes bearing three to ten spikes. *l.* two-thirds the length of the stem, ¼in. broad. Stems 1ft. to 3ft. high, slender. Himalayas, Australia, &c., 1892. Half-hardy. SYN. *C. gracilis* (R. H. 1892, p. 383). There is a form *variegata*, having leaves striped with white.

C. Drymeia (Drymeia). A synonym of *C. sylvatica*.

C. gracilis (slender). A synonym of *C. brunnea*.

C. japonica (Japanese). A garden name for *C. tristachya*.

C. maxima (greatest). A synonym of *C. pendula*.

C. paniculata (panicled). *fl.*, spikelets brown, numerous, crowded into a compound spike or panicle sometimes 4in. to 5in. long. Early summer. *l.* sometimes longer than the stems and ¼in. to ½in. broad. Stems 1ft. to 4ft. high, more or less triangular. Europe (Britain), &c. A stout species, forming large tufts.

C. scaposa (scapose). *fl.* brownish; spikelets ¼in. to ½in. long; cymes three or more to a scape, 1in. to 2in. broad; scapes longer or shorter than the leaves, stout, erect. Winter. *l.*, radical ones 1ft. long or more, 2in. broad, elliptic-lanceolate, acuminate at both ends; petioles sometimes 3in. to 4in. long. South China, 1883. Greenhouse. (B. M. 6940.)

C. secta (cut). *fl.*, spike lax, slender, drooping; spikelets pale brown. *l.* rigid, flat, keeled, much longer than the culms, ¼in. broad. Culms densely tufted, harsh, leafy, three-angled, 1ft. to 2ft. high, with scabrid edges. New Zealand, 1878.

C. tristachya (three-spiked). *fl.*, male spike solitary, linear, pedunculate; females twin, linear, approximating, slightly pedunculate. *l.* linear, striped with white. *h.* 1ft. Japan. Useful in pots for room decoration. SYN. *C. japonica* (of gardens).

C. Vilmorini (Vilmorin's). A graceful and very distinct species, with long and very narrow, densely-tufted leaves. New Zealand, 1897. It is easily increased by division of the tufts or by seeds. (R. H. 1897, p. 79, f. 26).

In addition to the above, *C. trifida* and *C. virgata* are in cultivation, but are at present rare.

CARICA. Including *Vasconcellea*. About a score species, natives of tropical America, form this genus. Flowers white, yellow, or greenish, unisexual and sometimes hermaphrodite; corolla of the male flowers salver-shaped, with an elongated tube; female flowers having five erect petals.

CARISSA. *Arduina* (described on p. 109, Vol. I.) is regarded by Bentham and Hooker as synonymous with this genus, which embraces about twenty species, natives of Africa, tropical Asia, and Australia.

C. Arduina (Arduina). The correct name of *Arduina bispinosa*.

CARLINA. *C. Chamæleon* is a synonym of *C. acaulis*.

CARLUDOVICA. This genus embraces about thirty species, natives of tropical America and the West Indies. To those described on p. 268, Vol. I., the following should be added:

C. Caput-Medusæ (Medusa's-head). *fl.* pale greenish-white, filamentose, forming dense heads. *l.* 3ft. to 4ft. long, cuneate-flabelliform, thickly plicate and bisected to the middle; segments three- to five-cleft, multifid towards the apex; ultimate segments recurved, acute. Habitat unknown, 1890. A handsome, stemless plant. (B. M. 7118.)

C. elegans (elegant). *l.* fan-like, 3ft. across, divided into four or five segments, which are again deeply cleft into narrow divisions. 1889. An ornamental, Palm-like plant.

Carludovica—*continued.*

C. Gardneri (Gardner's). *fl.* spirally disposed; spadix cylindrical; spathe four-leaved; peduncles axillary. *l.* obovate, narrowed to the petioles, bifid to the middle; lobes erect, oblong-ovate, acuminate. Brazil. (J. B. ii. 29, tt. 3-4.)

C. gracilis (slender). *fl.*, spadices pendulous, 4in. long, axillary, pedunculate, covered with twisted threads. *l.* alternate, 2ft. to 2½ft. long, bipartite, the divisions 2in. to 3in. broad, lanceolate, plicate, with ribs raised on the upper surface, bright green above, paler beneath. Caudex erect, waving. West Indies. SYNS. *C. Plumieri, Salmia palmifolia*.

C. latifolia (broad-leaved). *fl.*, spadix 2in. to 3in. long, scarcely rising above the spathe, with wavy stamens; scape short, thick, concealed by several spathe-leaves. *l.* springing from the top of the root, spreading, petiolate, 1½ft. to 2ft. long, rounded-flabelliform, strongly ribbed, bifid at apex, the lobes laciniate; petioles 4in. to 6in. long. West Indies, &c. SYN. *Ludovia latifolia* (B. M. 2950-1).

C. Laucheana (Lauche's). *l.* large, ensiform, plicate, green, coriaceous, bilobed at the apex, sheathing at base. Antioquia, 1893. Nearly allied to *C. plicata*. SYN. *Salmia Laucheana* (G. C. 1893, xiii., pp. 442, 481, f. 72).

C. microcephala (small-headed). *fl.*, spadix ¾in. long, covered with pale yellow flowers and long white filaments; spathes two, opposite, 1in. to 1½in. long. Spring. *l.* numerous at the top of the stem, 10in. to 18in. long, split to below the middle into two lanceolate, finely acuminate segments; petioles very slender. Stem 3½in. high, throwing out subterranean suckers. Costa Rica, 1880. (B. M. 7263.)

C. palmifolia (Palm-leaved). A provisional name for a plant introduced by B. S. Williams and Son.

C. plicata (folded). *fl.*, spadix 8in. long; rachis dense-flowered, much shorter than the petiole; spathes four, 4in. long. *l.* more or less deeply bifid, 3ft. to 4½ft. long; divisions ovate-lanceolate, acute or rounded at apex, argutely plicate towards the base. Caudex thick, woody, erect, 1ft. high, rarely taller, with a terminal tuft of many leaves. Brazil and Colombia.

C. Plumerii (Plumer's). *fl.*, spadices axillary, pedunculate, pendulous, cylindrical, 4in. long; bracts spathe-like, somewhat greyish. *l.* seven or eight at the apex of the stem, bifid to the middle, 2½ft. long, 8in. broad, plicate, rigid, very shiny, paler beneath; segments oblong, acute. Stem radicant. Martinique, &c.

C. Plumieri (Plumier's). A synonym of *C. gracilis*.

CARMICHÆLIA. New Zealand is the headquarters of the eighteen or so species embraced in this genus. To the one described on p. 269, Vol. I., the following should be added:

C. Enysii (Enys'). This species forms hard, compact patches 1ft. to 4ft. in diameter, and scarcely rising 1in. above the surface of the ground; in fact so dense are the branches that it is impossible to thrust the finger between them. New Zealand, 1877.

C. Mulleriana (Muller's). *fl.* whitish, striated purple, small, solitary or in pairs in the axils of the leaves. *l.*, leaflets one to three, small, obovate, emarginate, about ¼in. long, on a rather longer petiole. Branches slender, compressed, pinnately branched; branchlets filiform, compressed. *h.* about 2ft. 1887.

CARNATION. This lovely flower, which within the past decade has been considerably improved by the florists, bids fair to regain the popularity it enjoyed with the old-time gardeners. Colour, constitution, and form all show a considerable advance upon those varieties that were in existence even fifteen years or less ago. The flower is one of the oldest of which we have records, and Mr. Douglas informs us that even the much-prized yellow Carnation was grown in London towards the close of the sixteenth century. Popular as it is with a very large number of gardeners, it would be even more extensively grown were its merits as a town plant more widely known, as well as its comparatively easy cultivation. Perhaps the most important improvement is manifest in what are known as Border varieties, lists of which will be found under the headings of "Selfs" and "Fancies." In the Malmaison section, too, there has been a steady advance, especially as regards colour, though it must be confessed that this section seems more than ordinarily susceptible to fungoid diseases. For the benefit of the amateur we may say that the Selfs are of one colour only, whereas the Fancies comprise those varieties which, on account of their colours, do not fall within any of the other classes enumerated in Vol I.; for instance, those with a yellow or a white ground, or those mottled, flaked, or spotted with various colours.

Carnation—*continued.*

Culture. Some considerable space is devoted in Vol. I. to cultural details. There are, however, one or two points which may with advantage be touched upon here. First, in relation to propagation by seed, which is the method employed for raising new varieties. By far the best results are obtainable by careful hybridisation. Care must, however, be taken not to mix the classes. Selfs should be cross-fertilised with Selfs, Fancies with Fancies, &c.

Border Carnations are best planted from September to November in specially prepared quarters as advised in Vol. I. They may either be arranged in beds or in borders. They are generally propagated by layers in autumn, a form of increase already explained, but very plainly

FIG. 204. LAYERED CARNATION SHOOT.

shown in the illustration (Fig. 204). Those, however, who exhibit, grow the plants in pots. This is what Mr. Douglas, the Carnation specialist, says upon the subject in the "Book of Gardening":

The layers are inserted when ready in what the trade term "sixties," two plants in a pot, and they are wintered in garden-frames. They are placed fairly close to the glass, in order that they may have the full benefit of light and air. In some districts damp is troublesome, doing some damage to the leaves by what is termed "spot," but free ventilation will usually prevent its appearance. The work during winter consists in keeping the plants clean by removing dead and decaying leaves, stirring the soil on the surface, and by paying careful attention to the watering. In March they must be transferred to their flowering-pots. Two plants should be placed in a pot 8in. in diameter, or three in one 9in. The pots must be drained well, and the compost packed in firmly around the plants. In the process of transferring the plants from the small to the large pots, care must be taken not to disturb the roots more than is absolutely necessary. As the plants are repotted, they should be placed again into garden-frames until they are established, when the best way to treat them is to stand them out in the open air on a hard bottom of ashes. When the weather is mild, and the potting is not done until after the middle of March, it may be as well to stand them out-of-doors at once, as in the spring the frames are often required for half-hardy and tender plants. The flower-sticks ought to be placed to the plants very soon after they go out-of-doors, as high winds may snap off valuable plants close to the surface of the ground.

Careful attention must be given to watering all through the season, and as soon as the flower-buds show colour, the plants must be removed to the greenhouse, where they are to flower. Green-fly and thrips between them will

Carnation—*continued.*

disfigure both leaves and flowers if not dealt with at the outset. Fumigation must therefore be resorted to. To prevent the "grass" from drawing up weakly, air must be freely given, and when the flowers open they must be shaded from bright sunshine to preserve their beauty as long as possible. About the end of July layering may be commenced, and it will be better to place the plants out-of-doors, as the layers become drawn if the plants are kept under glass. Those plants growing in the open borders should be layered, of course, where they are. To do this scratch some of the ordinary garden-mould away from the base of the plants, replacing it with the compost already recommended.

Tree Carnations require rather different treatment. As the growths are mostly found up the main stems, they cannot very readily be layered, and are propagated by slips from the main stems of the plants. These strike freely in hot-beds, or early in the season in a forcing-house with a little bottom-heat. The temperature of the house should be about 55deg. If possible, the bottom-heat should be kept about 80deg. to 90deg. The slips will readily form roots in sixty-sized pots; when the young plants are established, they should be potted singly, and gradually inured to greenhouse culture. From May until the end of September Tree Carnations do best out-of-doors. The best potting soil for Carnations is three parts of good loam, one part of decayed manure, and one part of leaf-mould; sand to be added to lighten heavy soils. Mortar rubbish, broken up and run through a ½in. sieve, is also excellent to mix with the compost.

Malmaisons are also subjects for greenhouse treatment, except in summer. They require a minimum night temperature in winter of 55deg., rising in the daytime to a maximum of 65deg. They may be propagated similarly to the Tree Carnations. Great care with the watering must be observed in winter, as errors in this respect predispose the plants to fungoid attacks.

Besides the pests enumerated in Vol. I., and such diseases as Fairy Ring Spot, Rust, and Carnation Maggot, dealt with under special headings in the present volume, there are some few others which call for remark here. First as to Earwigs. These destroy the petals or so disfigure entire flowers, that they are useless. They are best trapped according to the methods detailed under **Earwigs**. Thrips attack the flower-buds, and in the open they should be syringed with weak Kerosene Emulsion; while under glass they are best destroyed by fumigation.

One of the most insidious pests which of late years have been discovered is a species of Eelworm (*Tylenchus*); this feeds in the stem, causing it to swell, burst, and eventually to die. Frequently these pests are introduced with potting soils; therefore, the greatest care must be observed. These Nematoid worms are very plentiful on grass lands, and where the soil has been obtained from such a source it would be prudent to first bake it. Those who keep large quantities of potting material stock it at least six months before using. The Eelworms are exceedingly minute, and thus readily escape observation. They show a marked partiality for the leaves of old plants. Where plants are badly infested they should be burnt, and the soil baked.

Cats and rabbits have a weakness for Carnation "grass" at all seasons; while in spring the sparrows play havoc with it, especially when the weather is severe. The best protection is afforded by pieces of narrow-meshed netting stretched over sticks bent semi-circular fashion and well pegged down at the sides. Black cotton stretched diagonally across the plants will, at any rate for a time, act as a deterrent against sparrows.

Under glass Red Spider is occasionally troublesome in dry weather. It may, however, like Green-fly and thrips, be ousted by fumigating.

Carnation—*continued.*

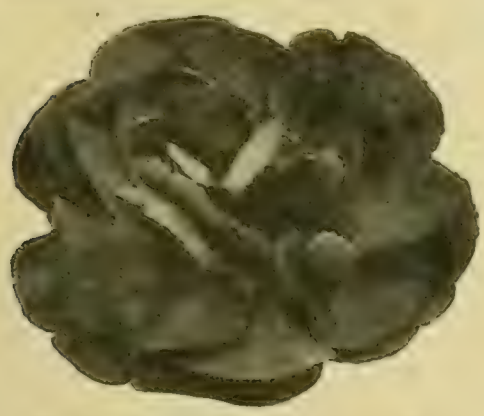

FIG. 205. SELF CARNATION MRS. JAMES DOUGLAS.

Varieties. The following in their respective classes may be recommended:

Crimson Bizarres. — BRUCE FINDLAY, EDWARD ROWAN, GEORGE RUDD, J. D. HEXTALL, J. S. HEDDERLEY, JOHN HARLAND, MASTER FRED, PATRIOT, PHŒBE, THADDEUS, VIRGIL, and W. WARDLE.

Pink and Purple Bizarres.—AUTOCRAT, HARMONY, MELODY, NIOBE, SQUIRE PENSON, and WILLIAM SKIRVING.

Scarlet Bizarres.—BIRETTA, DR. HOGG, DUKE OF YORK, JOSEPH CROSSLAND, OTHELLO, ROBERT HOULGRAVE, ROBERT LORD, and ROBERT MONK.

FIG. 206. FANCY CARNATION CZARINA.

Carnation—*continued.*

Purple Flakes.—AGRICOLA, BERNARD, CHARLES HENWOOD, FLORENCE NIGHTINGALE, MAGPIE, MRS. DOUGLAS, and SQUIRE WHITBOURN.

Rose Flakes.—JOHN KEET, LADY MARY CURRIE, MRS. ROWAN, ROSAMUNDI, ROSE OF STAPLEFORD, SYBIL, THALIA, TIM BOBBIN, and WILLIAM OF WYKEHAM.

Scarlet Flakes. — ALISEMOND. CANNELL JUNIOR, CERES, FRED PHILLIPS, GUARDSMAN, MATADOR, MISS CONSTANCE GRAHAME, and ROBERT CANNELL.

Fancies.—BRODRICK, yellow ground; CARDINAL WOLSEY, yellow ground; CZARINA (Fig. 206), yellow, with scarlet markings; DON JUAN, buff, flaked purple; GEORGE CRUICKSHANK, orange-buff, flaked crimson; MISS MACKENZIE, buff, flaked rose; MOGUL, yellow, with red markings; PELEGIA, deep pink, flaked light heliotrope; PERSEUS, yellow ground, edged orange-red; THE CZAR, yellow ground, with purple margin; and ZANZIBAR, yellow ground, spotted with scarlet.

Malmaisons.—LADY GRIMSTON, pinkish-white; LORD ROSEBERY, deep rose, very fragrant; MRS. MARTIN-SMITH, rose-pink; NELL GWYNNE, pure white; PRIME MINISTER, bright scarlet; TRUMPETER, rich scarlet.

Selfs.—AMY ROBSART, rich scarlet; BENDIGO, bluish-purple; BOADICEA, rosy-scarlet, excellent for the border; BRITANNIA, deep yellow; CINNAMON; COLUMBUS, lavender; DICK DONOVAN, blush-white; ENDYMION, salmon-pink; GARVILLE GEM, heliotrope; GERMANIA, deep yellow; HER GRACE, blush-pink, changing to pure white; ISINGLASS, deep scarlet; MRS. COLBY SHARPIN, cinnamon, excellent for the border; MRS. JAMES DOUGLAS, rich carmine rose, of fine form (see Fig. 205); NOX, crimson-maroon; SILVER STRAND, white; and WATER WITCH, blush-white.

Tree or Perpetual.—COMUS, white, vigorous; JULIAN, rich scarlet; PATROCLES, scarlet, free; PRIMROSE DAY, yellow; REGALIA, rose-pink; SARDIS, clear pink; SYLVANUS, purple; URIAH PIKE, dark crimson; WILLIAM ROBINSON, rich scarlet; WINTER CHEER, bright scarlet.

CARNATION FAIRY RING SPOT (*Heterosporium echinulatum*). This disease is due to a well-characterised fungus, whose clusters of fruit are borne in rings on light-coloured spots on the upper and under surfaces of the leaves as well as upon the leaf-stalks. The disease is a most destructive one under glass. Predisposing causes are great fluctuations of temperature, watering overhead, and lack of air. When once plants are badly attacked, there is little chance of cure, and they had better be pulled up and burned. In the case of light attacks, all the diseased leaves should be removed, the plants isolated, and the remainder sprayed with potassium sulphide (½oz. to 1gall. of water). If this is not done, the disease will be certain to appear the following season, as it is tided over the winter by means of sclerotia; these in spring yield conidia, which, on coming in contact with Pink or Carnation foliage, begin again the cycle.

CARNATION MAGGOT (*Hylemia nigrescens*). This is a formidable pest of the Carnation cultivator. The insect responsible for the mischief belongs to the order *Diptera*, and is the grub of a small black fly somewhat resembling the common house-fly in appearance. This insect deposits its eggs upon the leaves of Carnations, usually selecting seedlings or prepared cuttings and layers. Less often older plants are attacked. From the eggs hatch out yellowish-white grubs, which feed upon the pith, leaving little more than a skin covering. If infested Carnations are constantly examined, there will be found some whitish streaks. The only thing then to be done is to dislodge the pests by opening the foliage with a pin or a needle, and burning the dead and decaying portions. The plants may also be sprayed about the time the insects are on the wing with some distasteful insecticide—a solution of soluble petroleum (a wineglassful to 1gall. of warm water), or even with weak Kerosene Emulsion.

CARNATION RUST (*Puccinia arenariæ*). This fungus attacks both Pinks and Carnations, as described in Vol. III., p. 248, under **Puccinia.** It is also common on many wayside plants belonging to the same Natural Order. A weak solution of Condy's Fluid will probably prevent it from spreading.

CARNEOUS. Flesh-coloured.

FIG. 207. DIONÆA MUSCIPULA.

CARNIVOROUS PLANTS. This term is usually applied to genera like *Drosera*, *Pinguicula*, *Nepenthes*, *Dionæa*, and *Utricularia*, which are thought by some to possess the power of absorbing nitrogenous substances through their leaves, and digesting them within their tissues. Several of the best known are British plants—

FIG. 208. DROSERA ROTUNDIFOLIA (natural size).

Carnivorous Plants—*continued.*

Drosera rotundifolia and *D. intermedia* for instance. The most interesting of all, however, is *Dionæa muscipula* (Fig. 207), or Venus' Fly-trap.

Others regard these plants as insect-catching rather than insect-eating, their contention being that the plants have no power to cast away the captured prey, which gradually decays upon the leaf. In fact, it has been observed that when the creature trapped proves to be a rather large insect, or perhaps a spider, the decomposition that follows after death frequently causes the destruction of the leaf.

As *Drosera rotundifolia* will serve as well as any to illustrate the functions of these interesting plants, it has been selected here (Fig. 208). The leaf is the interesting part of the plant. It bears on its upper surface a large number of filaments, or tentacles, as they are usually called. Some large leaves have as many as 250, but usually there are not more than 100. Those in the marginal row, which are often ¼in. in length, spread out in the plane of the surface of the leaf; the members of the next row are shorter and rather more erect, and so on, till those in the central part of the leaf are very short and quite erect (see Fig. 209). There are a very few long tentacles on the upper part of the leaf-stalk. At the extremity of each tentacle is a gland surrounded by a globule of a clear fluid of the consistency of gum. It is not certain whether the tentacles are hairs modified to perform a special duty, or prolongations of the leaf itself; but at any rate the framework of the leaf enters into them, as will be seen in the much-magnified drawing of one of the glands (see Fig. 210). The central spiral threads are in connection with the fibro-vascular system of the leaf; outside of them are two or three layers of simple cells containing a purplish fluid, which undergoes a change when the gland is irritated. The pale green leaf, with its crimson tentacles, surmounted with glistening drops of liquid, looks very beautiful in the sunshine, and well earns for the plant the common name of Sundew. The plant is at its best in July and August, and flowers in the latter month.

FIG. 209. LEAF OF DROSERA ROTUNDIFOLIA (magnified two diameters).

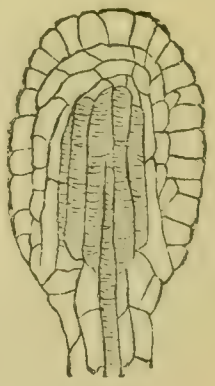

FIG. 210. GLAND OF DROSERA ROTUNDIFOLIA (much magnified).

Suppose a tiny fly to alight upon the central part of a leaf, it will be held there by the sticky substance surrounding the glands on the tentacles. The glands at once begin secreting a watery fluid closely resembling pepsin in its properties, and which, like it, dissolves organic food. At the same time an impulse travels along the fibro-vascular system to the outer tentacles. These in the course of an hour gradually turn over, the nearer ones first and the remoter ones later, on to the insect, and there pour out the same fluid. When, after a few days,

Carnivorous Plants—*continued.*

the nutritive substances have been dissolved out, the tentacles regain their original position. Should the fly be caught on one side of the leaf, usually the tentacles of that side only are inflected. Often the edge of the leaf bends over as well as the tentacles. The marginal tentacles turn inwards and carry the fly, or what not, to the centre of the leaf, there to be acted on, if it should be caught on them alone. Darwin says that on examining a dozen plants, having fifty-six fully-expanded leaves, he found thirty-one with dead insects or their remains, and on one large leaf the remains of thirteen distinct insects. He mentions the case of a butterfly — the Small Heath (*Cœnonympha pamphilus*) — being caught, and we have on two occasions found a specimen of the small Blue Dragon-fly firmly held, though by no more than one leaf.

If the substance deposited on the leaf contains a good supply of nitrogen compounds easily dissolved, such as raw meat, hard-boiled eggs, or fragments of insects, the movement of the tentacles is very rapid. Darwin mentions an instance in which a piece of raw meat placed on a gland caused inflection in five or six minutes, whereas a piece of cinder only caused movement in about four hours. Tickling or repeated touching will in time cause the tentacles to inflect, but a tap will not; so that the wind blowing blades of grass against the plant does not cause unnecessary action and a waste of energy. The centre of irritability seems to be in the gland, for if this is cut off the tentacles will not inflect, whereas almost the tiniest particle of nitrogenous matter deposited on the gland will cause motion, testifying to its great sensitiveness. As a result of stimulation the purple particles in the cells of the glands aggregate into variously-shaped masses, which float about in a now colourless fluid.

In the case of *Dionæa muscipula* the sensitive bristles are situate in the centre of each lobe of the leaf. When these are touched, the outer edges close up, thus preventing the escape of the fly or other intruder.

CARNIVOROUS SLUGS (*Testacella*). Some points in connection with these useful Slugs are dealt with in Vol. IV., under **Testacella.** There, however, but

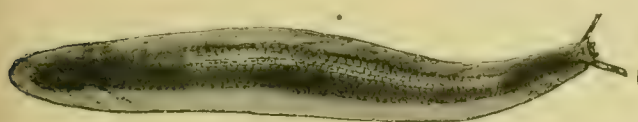

FIG. 211. CARNIVOROUS SLUG (*Testacella haliotidea*).

two species are mentioned—*T. haliotidea* (Fig. 211) and *T. Maugei*. There is a third, *T. scutellum*. The first-named species is fairly abundant in certain districts—Oxfordshire, for instance—though the Slugs are seldom recognised as beneficial to the gardener, and are often destroyed. They are, however, chiefly confined to the South-west portion of England. A popular but erroneous impression is that these Slugs do not come out of the soil; but they have been frequently found upon lawns when searching for worms with a light, and upon gravel walks. Nor do they confine their attention entirely to worms; they will not hesitate to attack Slugs of other species. Their method of attack on worms is to seize their unfortunate prey some distance up, inflict a wound—probably by means of the toothed lingual ribbon—and draw it in thus doubled up. The worms are not swallowed alive. *T. scutellum* differs chiefly from *T. haliotidea* in being of a more pronounced yellow, while the lines on the back meet in front of the shell instead of merging under its edge. *T. Maugei* has a much larger shell than the other two species.

CARPENTERIA. In the Southern counties of England this very fine shrub is quite hardy, but North of London it requires the protection of a wall, or even of a cool greenhouse. It is by no means exacting in its cultural requirements so long as the soil is fairly rich, moist, and well drained. It is a rather difficult plant to strike from cuttings, but it may be readily propagated by layering. The layers should be tongued, and a little damp moss and sand pressed into and over the incision, the whole being kept moist by frequent syringings.

CARPINUS. Of this genus there are nine species, broadly dispersed over North temperate regions. To those described on p. 272, Vol. I., the following should be added:

C. caroliniana (Carolina). A synonym of *C. americana.*

C. japonica (Japanese). *fl.*, male catkins cylindric, with spreading, ovate bracts; females large, ellipsoid, with large, toothed, imbricated bracts. *l.* lanceolate-ovate, long-pointed, doubly serrated, 2in. to 4in. long, ¾in. to 1½in. broad; petioles ¼in. to ½in. long, and, as well as the branchlets and peduncles, rusty-tomentose. Japan, 1889. A dwarf tree.

C. Ostrya (Ostrya). A synonym of *Ostrya virginica.*

CARPOCAPSA. This is a genus of very small Moths, one species of which is exceedingly destructive to Apple trees—*C. pomonella*, or Codlin Moth. Occasionally, too, the larvæ of another species (*C. splendidana*) are found in Walnuts, though more usually in Acorns.

CARPODETES RECURVATA. A synonym of **Stenomesson recurvatum** (which *see*).

CARPOLYZA. SYN. *Hessea.* This genus is monotypic. Leaves two to four, contemporary with the flowers.

CARPOPOGON. A synonym of **Mucuna** (which *see*).

CARREGNOA. A synonym of **Tapeinanthus** (which *see*).

CARRIERIA (named in honour of E. A. Carrière, Editor-in-chief of the "Revue Horticole"). ORD. *Bixineæ.* A monotypic genus. The species is a hardy tree with the general aspect of *Idesia polycarpa*, but with a woody, capsular fruit. It probably requires similar culture to **Idesia** (which *see*).

C. calycina (having a prominent calyx). *fl.* few, in a simple, terminal raceme; sepals five, white, rounded, connivent, very pilose. *fr.*, an elongated capsule, dehiscing in three valves *l.* alternate, caducous, petiolate, ovate, toothed, coriaceous, glabrous. Se-Tchuen, 1896. (R. H. 1896, p. 47, f. 170.)

CARRION FLOWER. *See* **Stapelia.**

CARROT. In addition to the varieties recommended in Vol. I. for forcing, the following are noteworthy: Early Scarlet Horn, Little Gem, and Scarlet Perfect.

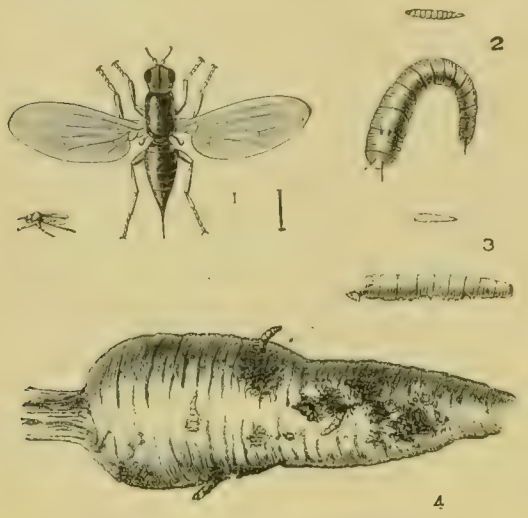
CARROT GRUBS (*Psila rosæ*). These pests are most abundant in this country, as well as in many parts of the Continent, but especially in Germany. The life-history and depredations of the insect responsible for the mischief were somewhat fully dealt with in Vol. I. Little, therefore, remains to be added here. The perfect insect, a fly (Fig. 212, 1), is on the wing in May, when the female, which has a more pointed body than the male, furnished with an ovipositor, lays the eggs in the soil in the vicinity of the roots, the insect actually working beneath the surface for the purpose. The larvæ (Fig. 212, 2), when hatched out, make for the food ready to hand, and if Carrots showing signs of withered tops are lifted, they will be found covered with rusty spots (Fig. 212, 4), somewhat similar to those arising from iron-mould. The pupa-state (Fig. 212, 3) is passed beneath the soil, or it may be in the stored Carrots. There are several broods in the season, and the repeated attacks of the pests cause the Carrots to become rotten in bad cases, and always to lessen their market value.

Wood-ashes are very distasteful to the grubs of the Carrot Fly, and should be always employed. Some cultivators also add paraffin at the rate of 1qt. to a barrow-load of the wood-ashes, and apply this on the

Carrot Grubs—*continued.*

surface when the young plants are about 4in. high. Watering with a solution of soluble petroleum (1oz. to the gallon of water) is also effectual if done when the fly is on the wing. The soil should also be made firm so that the female is unable to go beneath the surface for egg-deposition.

Wireworms are also very destructive to Carrots, and are most difficult to deal with, especially in small gardens which



By Permission of the Board of Agriculture.

FIG. 212. CARROT FLY *(Psila rosæ).*

Showing 1, perfect Insect, natural size and magnified; 2, Larva, natural size and magnified; 3, Pupa, natural size and magnified; 4, infested Carrot with rusty spots.

have to be kept continually cropped. Wood-ashes in this case, too, have been found of exceeding benefit. They should be well dug in when the soil is prepared, and also plentifully employed in the drills when the seed is sown. Gas-lime, where it can be employed early in winter, and the quarters allowed to remain uncropped, is also excellent for Wireworms.

CARROT, ROCK. *See* **Thapsia edulis.**

CARROT, TREE. *See* **Thapsia edulis.**

CARTESIA. A synonym of **Stokesia** (which *see*).

CARTHAMUS CORYMBOSUS. A synonym of **Cardopatium corymbosum** (which *see*).

CARTHAMUS. This genus embraces about twenty species, natives of the Mediterranean region, Central Europe, and Central Asia, and includes **Kentrophyllum** (which *see*).

C. mitissimus (least spiny). A synonym of *Carduncellus mitissimus.*

CARTONEMA (from *kartos*, shorn, and *nema*, a filament; in allusion to the shape of the filaments supporting the pollen-bags). ORD. *Commelinaceæ.* A genus including five or six species of greenhouse herbs with leafy stems, simple or branched at the base, all natives of Australia. Flowers disposed in simple, terminal spikes or racemes, solitary within small or narrow bracts. *C. spicatum* has been introduced, but is probably not now in cultivation.

CARUM. Including *Petroselinum* and *Zizia.* The genus embraces about fifty species, mostly found in temperate regions.

CARUMBIUM (of Kurz). A synonym of **Sapium** (which *see*).

CARUMBIUM (of Reinwardt). A synonym of **Homalanthus** (which *see*).

CARUNCULARIA. Included under **Stapelia** (which *see*), the correct name of *C. pedunculata* being *S. lævis.*

CARVI. *See* **Carum Carvi.**

CARYA. SYN. *Hicorias.* Eleven species are referred to this genus by Bentham and Hooker. To those described on p. 274, Vol. I., the following should be added:

C. sulcata (furrowed). *fl.*, catkins very long, pedunculate, glabrous. March and April. *fr.* ovate, 2½in. long, pericarp very thick; nut elongated at both ends, conspicuously pointed, quadrangular. *l.*, leaflets seven to nine, obovate-oblong, acuminate, serrated, glabrous above, tomentose beneath. A large tree, with scaly bark; it resembles *C. alba.* SYN. *Juglans sulcata.*

CARYOCAR. Including *Pekea.* About eight species, natives of tropical America, are included in this genus. Flowers disposed in terminal racemes; calyx deeply five- or six-cleft; petals five or six, imbricated; stamens numerous. Fruit sub-drupaceous. Leaves opposite, digitately three- to five-foliolate; leaflets coriaceous. *C. nuciferum* is known as the Saouari, Souari, Suwarrow, or Butter Nut.

CARYOPSIS. *See* **Cariopsis.**

CARYOPTERIS. SYNS. *Barbula, Mastacanthus.* This genus includes five species of erect or rambling shrubs, natives of Northern and Eastern Asia and the Himalayas. Calyx deeply five-cleft; corolla tube short, the middle lobe of the lower lip larger, crisped or fimbriate; stamens four. Leaves opposite, acuminate, minutely gland-dotted.

CARYOTA. About a dozen species are included here; they inhabit tropical Asia, the Malayan Archipelago, New Guinea, and tropical Australia. To those described on pp. 274-5, Vol. I., the following should be added:

C. Alberti (Albert's). A synonym of *C. Rumphiana.*

C. furfuracea (scurfy). The correct name of *C. purpuracea.* The plant is identical with *C. mitis.*

C. obtusa (obtuse). This only differs from *C. urens* in the shorter, unexpanded male flowers, slightly in the fruit, and in the more rounded and crenate tips of the leaflets. Upper Assam.

C. o. æquatorialis (Equatorial). *fl.*, males larger than in the type; stamens more than 100. *l.* having pinnules more acute and more deeply crenate or serrated. Malay Peninsula. According to Sir J. D. Hooker, *C. ochlandra* is probably identical with this.

C. ochlandra (yellow-stamened). Probably synonymous with *C. obtusa æquatorialis.*

C. plumosa (feathery). A species supposed to be newly introduced, and distributed by a Belgian firm without description or information as to origin.

C. Blancoi, C. elegans, C. majestica, and *C. speciosa* are in cultivation at Kew, but are very scarce.

CARYOTAXUS. A synonym of **Torreya** (which *see*).

CASCARILLA GRANDIFOLIA. A synonym of **Cosmibuena obtusifolia latifolia** (which *see*).

CASEARIA includes *Iroucana.*

CASSAVA WOOD. *See* **Turpinia occidentalis.**

CASSEBEERA. All the species require stove treatment, and the soil which suits them best is peat of a sandy nature, allowing a free passage to the water, which should be liberally administered to the roots.

C. triphylla. The characteristic of this Fern responsible for the specific name is well shown in Fig. 213.

CASSELIA (a commemorative name). ORD. *Verbenaceæ*. A small genus (five or six species) of dwarf, stove herbs, under-shrubs, or shrubs, confined to Brazil. Flowers few, in axillary racemes; corolla limb sub-bilabiate. Leaves opposite, membranous, deeply-toothed or rarely entire. *C. integrifolia* (F. d. S. 361; P. M. B. xv. 75) has been introduced, but is probably no longer in cultivation.

CASSELIA (of Dumortier). A synonym of **Mertensia** (which *see*).

CASSIA. Including *Chamæfistula*. The species of this genus are broadly distributed over the warm regions of the globe. To those described on p. 276, Vol. I., the following should be added:

C. australis (Southern). *fl.* yellow, two to six in a loose umbel, on peduncles usually shorter than the leaves; petals ½in. long. *l.*, leaflets usually eight to ten pairs, oblong, lanceolate, or almost linear, ¼in. to 1in. long, the margins recurved or revolute. *h.* 3ft. Australia (re-introduced), 1890. An erect, greenhouse shrub. (B.M. 2676.) SYN. *C. Barrenfieldii*.

C. Barrenfieldii (Barrenfield's). A synonym of *C. australis*.

C. bicapsularis (two-capsuled). *fl.* bright yellow, medium-sized; racemes copious, corymbose, as long as the leaves. *l.* distinctly petiolate; leaflets six to eight, membranous, ½in. to ¾in. long. Branches virgate. Tropical America, 1739 and 1890. Greenhouse or half-hardy shrub. SYN. *C. Reinwardtii*.

FIG. 213. CASSEBEERA TRIPHYLLA.

C. bracteosa (large-bracted). A synonym of *C. didymobotrya*.

C. Burmanni (Burmann's). A synonym of *C. obovata*.

C. calliantha (beautiful-flowered). A synonym of *C. multijuga*.

C. coquimbensis (Coquimbo). *fl.* 1½in. in diameter; sepals oblong, obtuse, about half the length of the orange-yellow petals; dorsal petal obcordate, the two lateral ones broadly obovate, the anterior ones smaller, obovate-oblong; cymes axillary, many-cleft, sub-corymbose. September. *fr.*, pods about 4in. long, over ½in. broad, stipitate, flattened, acute at base, mucronate at tip. *l.* 2in. to 4in. long; leaflets four to six pairs, four to eight lines long, sessile, elliptic-oblong or almost rounded, apiculate, pale green. Chili, 1886. Greenhouse shrub. (B. M.7002.)

C. didymobotrya (twin-clustered). *fl.* orange; racemes simple, erect, 6in. to 12in. long, corymbose, from the axils of the upper leaves; bracts caducous, ½in. long. *l.* 6in. to 16in. long; leaflets four to six pairs, oval or elliptic, obtuse or scarcely acute. *h.* 7ft. to 10ft. Angola, 1866. Greenhouse shrub or small tree. SYN. *C. bracteosa*.

C. Fistula (Fistula). *fl.*, calyx ¼in. to ½in. long, caducous; petals veined bright yellow, ¾in. to 1in. long, obovate, shortly clawed; racemes as long as the leaves. *fr.* cylindrical, almost woody, 8in. to 10in. long. *l.* 1ft. or more in length; leaflets eight to sixteen, 2in. to 6in. long, ovate, narrowed to the apex, distinctly stalked, pale green, strongly veined. *h.* 20ft. to 30ft. India, &c. An erect tree.

C. multijuga (many-paired). *fl.* large, in terminal racemes. *l.* twenty to twenty-five pairs, oblong-linear or oblong-elliptic, glabrous, somewhat whitish beneath. Brazil, 1869. Tree. SYN. *C. calliantha*.

C. obovata (obovate). *fl.*, sepals glabrous, very obtuse; corolla pale yellow, medium-sized; racemes narrow, distinctly pedunculate, equalling or exceeding the leaves. July. *fr.* reniform. *l.* distinctly petiolate, 2in. to 3in. long; leaflets obovate-oblong, membranous, very glaucous, obtuse. *h.* 1ft. to 4ft. India, &c., 1640. Annual. SYNS. *C. Burmanni*, *C. Senna*.

C. Reinwardtii (Reinwardt's). A synonym of *C. bicapsularis*.

C. Senna (Senna). A synonym of *C. obovata*.

CASSINE. *Maurocenia* is synonymous with this genus.

CASSINIA. This genus includes about eighteen species, natives of Australia, New Zealand, and South Africa. Leaves small, persistent. To the species described on p. 276, Vol. I., the following should be added:

C. fulvida (fulvous). *fl.-heads* white, ⅛in. to ¼in. long, in termina corymbs of four or five. *l.* ¼in. to ½in. long, linear, obtuse fulvous beneath, shining above. *h.* 10ft. to 15ft. New Zealand. Plant glutinous. (R. G. 1890, p. 241, f. 56.) SYN. *Diplopappus chrysophyllus* (of gardens).

C. leptophylla (smooth-leaved). *fl.-heads* white, ⅛in. to ¼in. long, in terminal, hemispherical corymbs. August. *l.* erect or spreading, rarely recurved, $\frac{1}{12}$in. to $\frac{1}{20}$in. long, glabrous above, tomentose beneath. *h.* 10ft. to 15ft. New Zealand, 1821. (P. F. G. iii., p. 16.)

CASSINIACEÆ. Included under **Compositæ** (which *see*).

CASSIOPE. To grow the members of this genus satisfactorily a thoroughly well-drained, moist, peaty soil, and a position just shaded from the fierce mid-day sun is advisable. On no account should water be allowed to become stagnant at the roots, or failure will result.

CASSIPOUREÆ. Included under **Rhizophoreæ** (which *see*).

CASSUVIUM. A synonym of **Anacardium** (which *see*).

CASSYTHEÆ. A tribe of **Laurineæ** (which *see*).

CASTALIA. A synonym of **Nymphæa** (which *see*).

CASTANEA. Only the two species described on p. 277, Vol. I., are contained in this genus. *See also* **Castanopsis**.

C. americana (American). A variety of *C. sativa*.

C. chrysophylla (golden-leaved). A synonym of *Castanopsis chrysophylla*.

C. japonica (Japanese). A form of *C. sativa*.

C. sativa americana (American). *fr.* smaller and sweeter than in the type. *l.* acute at the base; young ones lepidote, puberulous. United States.

C. s. japonica (Japanese). A variety having the under-side of the young leaves covered with white pubescence. Japan, 1889.

C. vulgaris (common). A synonym of *C. sativa*.

C. crenata and *C. dentata* are other good kinds.

CASTANEACEÆ. Included under **Cupuliferæ** (which *see*).

CASTANEOUS. Chestnut-coloured.

CASTANOPSIS (from *Kastanon*, a Chestnut, and *opsis*, resemblance; this genus is related to *Castanea*). ORD. *Cupuliferæ*. A genus embracing about twenty-five species of stove, greenhouse, or hardy trees, rarely shrubs; one is found in California, and the rest are Asiatic. In habit they closely resemble some of the Oaks; but they differ in the closed fruiting involucre, enclosing one to four nuts, being covered with spines or tubercles, and often splitting irregularly. Two of the species have been introduced, but only one calls for mention here. It thrives in ordinary soil, in any sheltered spot, and may be propagated by cuttings.

C. chrysophylla (golden-leaved). *fl.*, catkins dense, one-half the length of the leaves. *fr.* densely echinate, maturing in the second year. *l.* 4in. to 5in. long, broadly lanceolate, acuminate, acute at base, entire, coriaceous, deep green above and (especially the young ones) golden-lepidote below, becoming fuscous when old. Oregon, 1848. A dwarf, evergreen shrub. (G. C. 1897, ii., p. 411, f. 20.) SYN. *Castanea chrysophylla* (B. M. 4953).

CASTELA (a commemorative name). ORD. *Simarubeæ*. A small genus (six species) of stove or greenhouse, spiny, American shrubs, with inconspicuous, axillary flowers, and small, alternate, simple leaves. Two species have been introduced, but they are of little horticultural value. One of them, *C. Nicholsoni* (Goatbust), is remarkable for its bitterness, which resembles that of Quassia.

CASTILLEJA. Painted Cup. About twenty-four species, mostly North American, are included in this genus.

CASTRA. A synonym of **Trixis** (which *see*).

CASUARINA. The species of this genus (*i.e.*, of the natural order *Casuarineæ*) number about two dozen. To those described on p. 278, Vol. I., the following should be added:

C. africana (African). A synonym of *C. equisetifolia.*

C. indica (Indian). A synonym of *C. equisetifolia.*

C. nodiflora (node-flowering). *fl.*, male amenta terminal, short; cones sub-terminal, sub-globose, small, about eight-ranked. Branchlets slender, rather short, undivided or slightly branched, four-angled. New Caledonia, 1823.

C. stricta, of Miquel. A synonym of *C. distyla.*

C. sumatrana (Sumatran). *fl.*, cones sub-terminal, large, ellipsoid or globose. Branchlets dense, very slender, triquetrous. Sumatra, 1832. An excessively branched shrub or tree, useful for bouquets on account of its plumose branchlets.

CATACHÆTUM. *See* **Catasetum.**

CATAKIDOZAMIA. Included under **Macrozamia** (which *see*). *C. Macleayi* is a synonym of *Macrozamia Perowskiana.*

CATALPA. About half-a-dozen species are embraced in this genus; they are found in China, Japan, North America, and the West Indies. To the species, &c., described on pp. 278-9, Vol. I., the following should be added:

C. bignonioides. Of this species there are several varieties in cultivation in European gardens—*aurea* (golden), *foliis argenteis variegata* (having silvery-variegated leaves), *grandiflora* (large-flowered), and *purpurea* (purple).

C. cassinoides (Cassine-like). A form having leaves intermediate between those of *C. Bungei* and *C. speciosa.* Brazil, 1890.

C. cordifolia (cordate-leaved). The plant so-called in gardens is a very hardy and vigorous form of *C. bignonioides.*

C. Kæmpferi nana (dwarf). A synonym of *C. (K.) Wallichiana.*

C. umbraculifera (umbrella-bearing). A handsome shrub or small tree, 9ft. to 12ft. high, with a rounded, compact head. China, 1838. Perhaps a garden variety.

C. Wallichiana (Wallich's). This is thought to be a Chinese form of *C. Kæmpferi*; it is of rather low growth. 1890. SYN. *C. Kæmpferi nana. C. pumila* and *C. Thunbergi* have been introduced to Continental gardens.

CATAPPA. Included under **Terminalia** (which *see*).

CATARIA. A synonym of **Nepeta** (which *see*).

CATASETUM. SYN. *Catachætum.* Including *Monachanthus.* This genus comprises upwards of eighty species, mostly natives of tropical America, extending from Brazil as far as Mexico. Lip fleshy, sessile at the base of the column; pollen masses four. To the species and varieties described on pp. 279-80, Vol. I., the following should be added:

C. apertum (open). *fl.* apple-green, spotted with brown; segments concave, forming a kind of cup; scape erect, 6in. long. *l.* lanceolate, 6in. long. Pseudo-bulbs fusiform, 5in. long. Habitat not recorded, 1895. Allied to *C. macroglossum.*

C. atratum (dark). *fl.*, sepals and petals green outside, shaded and spotted with purple on the inside; lip green, fringed, with a yellow, recurved flap at the end; raceme decurved. July. Brazil. (W. O. A. x., t. 480.)

C. barbatum proboscideum (proboscis-like). This only differs from the type in the beard of the lip being green. 1889.

C. b. spinosum (spiny). *fl.*, sepals and petals green, barred with brown, narrower than in the type; lip white, with a spine-like point at the apex. 1891. (L., t. 293.)

C. Bungerothi (Bungeroth's).* *fl.* white, very showy; sepals and petals lanceolate, very acute, spreading; lip large, transversely oblong, deeply concave, shortly and obtusely spurred, bidentate at apex; racemes many-flowered. *l.* lanceolate, very acute, 8in. to 9in. long, 1½in. to 2in. broad. Pseudo-bulbs fusiform, 5in. to 9in. long. Equatorial America, 1887. (B. M. 6998; G. C. ser. iii., i., p. 142; I. H. ser. v. 10; W. O. A. viii., t. 352.) See Fig. 214.

C. B. album (white). *fl.* pure white with the exception of a delicate rose-coloured spot on the lip. 1888.

C. B. aureum (golden). *fl.* light yellow. Venezuela. A distinct variety. (L. iii., t. 116.)

Catasetum—*continued.*

C. B. Pottsianum (Potts'). *fl.*, petals prettily marked with purple; centre of the lip having a few spots. 1887. (L. iii., t. 104.)

C. B. Randi (Rand's). *fl.* yellow, with a spot of deep apricot-yellow in the spur. 1890. (I. H. xxxvii., t. 117.)

C. chloranthum (yellow-flowered). *fl.* generally rather larger than in *C. macrocarpum* (which this species resembles in general aspect); sepals pale green, with rosy blotches; petals also pale green, but more heavily blotched. 1894.

C. Christyanum (Christy's). *fl.* large, spreading, each with a narrow bract at base; sepals dark reddish- or chocolate-brown, the dorsal ones erect, the lateral ones spreading; petals lighter brown, pale-spotted at base; lip green and purplish, short, with a bluntly-conical, saccate pouch and a three-lobed limb, the lateral lobes with long, purple fringes; raceme erect, six-flowered. Autumn. *l.* lanceolate-lorate, acuminate, plaited. Stems fusiform, jointed, 6in. to 8in. long. Amazons. (W. O. A. 83.)

C. C. obscurum (obscure). *fl.*, sepals and petals blackish-purple; side lobes of the lip dark, rich purple, the middle lobe brownish-olive-green, and the wall around the mouth of the apex light ochre, marked with red. 1885.

C. ciliatum (ciliated). *fl.* rather over 1in. across, somewhat resembling bees on the wing; sepals and petals greenish-yellow, the latter erect, the former reflexed; lip whitish, triangular, concave, tipped with maroon-purple, and having purple bristle-like hairs ⅛in. long on the sides near the base; pedicels and column purplish. Amazons, 1891.

C. Claveringii (Clavering's). A synonym of *C. macrocarpum.*

C. collare (banded). *fl.*, sepals bright green; petals whitish-green; lip white, slightly shaded with green on the outer surface, very thick and fleshy. Venezuela, 1895.

C. costatum (ribbed). *fl.*, sepals and petals yellowish; side lobes of the lip erect, triangular, the upper border ciliated; "the mid-lobe . . . . goes out into a low, blunt, small triangle, standing over the long, blunt conus, so very remarkable by the presence of some lighter ribs running at each side, but which are not very conspicuous as long as the lip is fresh" (Reichenbach). 1887.

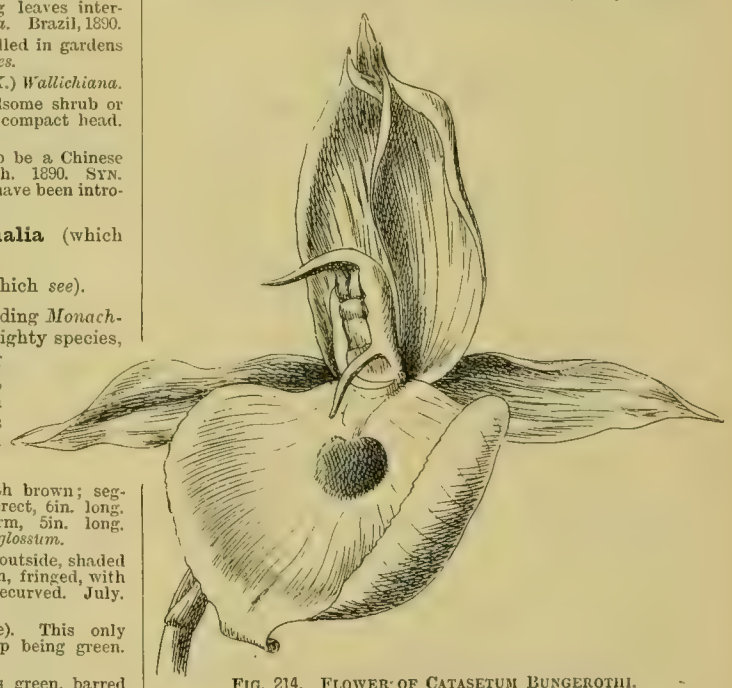


FIG. 214. FLOWER OF CATASETUM BUNGEROTHI.

C. cristatum stenosepalum (narrow-sepaled). *fl.*, sepals purplish-brown, narrow; petals entire, purple, striated with dark purple. 1887. (I. H. ser. v., t. 71.)

C. decipiens (deceptive). *fl.*, sepals and petals brownish-purple, with darker spots, lanceolate, acute; lip yellow outside, light brown inside, cup-shaped; column white, having two long spurs; inflorescence pendent. Venezuela, 1888. *l.* lanceolate, acute. Pseudo-bulbs fusiform, 3in. to 4in. long. (L. iii., t. 144.)

Catasetum—*continued.*

C. discolor (two-coloured). *fl.* in erect spikes, produced from the base of the pseudo-bulbs; sepals and petals greenish; lip yellow outside, hairy and lined with brown inside, cup-shaped, with two purplish lateral fringes. Pseudo-bulbs narrow, tapering. Pernambuco, 1844. (L. i., t. 38.)

C. d. vinosum (wine-red). *fl.* of a vinous-red colour. Brazil, 1894.

C. ferox (fierce). *fl.* dirty green outside and pea-green within. spicate. Habitat not recorded, 1895.

C. fimbriatum (fringed). *fl.* yellowish-green; sepals linear, apiculate; petals rather longer, fleshy; lip fleshy, three-lobed, the lobes fringed with long, mostly bifid fimbriæ; scape about nine-flowered. August. *l.* lanceolate, acuminate, slightly plicate. Pseudo-bulbs about 6in. long, six- to eight-leaved. Pernambuco. (B. M. 7158.)

C. f. Cogniauxi (Cogniaux'). *fl.*, sepals white, spotted and suffused with rose-purple; lip deeply fringed, the lower part pale or greenish-yellow spotted with reddish-brown, the upper part whitish. 1895. (L. xi., t. 499.)

C. f. platypterum (broad-winged). *fl.* large; sepals and petals greenish-white, streaked and dotted with purplish brown; lip "Garlic-green." 1889.

C. f. viridulum (greenish). *fl.*, sepals and petals green, spotted with reddish-purple; column greenish-white, spotted with purple. 1886.

C. Finetianum (Finet's). *fl.* in lax spikes; sepals and petals whitish, suffused and spotted with purple, long and narrow; lip oblong, nearly acute at the tip, the margins entire, strongly incurved. Colombia, 1894.

C. galeritum (capped). *fl.* rather large; sepals and petals pale green, spotted brown, oblong, acute; lip pale green, saccate, oblong, conical at apex, ochreous in front, marked pale green around the mouth, and marked brown on a yellow ground inside; raceme several-flowered, lax. Colombia (?), 1886. (L. ii., t. 67.)

C. g. pachyglossum (thick-lipped). *fl.* having an almost square, thick, obtuse-angled lip. 1889.

C. Garnettianum (Garnett's). *fl.* about 1¾in. across; sepals and petals light green, thickly spotted with chocolate-brown, ⅜in. long; lip white, ⅜in. long, divided into bristles at the apex and with shorter bristles on the margins below the middle; scape erect, 4in. long, several-flowered. *l.* lanceolate, 4in. long. Pseudo-bulbs 1in. to 2in. long, compressed-ovate or conical. Allied to *C. barbatum*, but smaller. 1888. (B. M. 7069.)

C. glaucoglossum (glaucous-lipped). *fl.* large; sepals brown, ligulate, acute; petals glaucous, spotted brown, much larger than the sepals, oblong, acute; lip glaucous, spotted brown inside, having a depressed, rounded sac, and a triangular mouth; raceme stout, bearing several flowers, deflexed. Mexico, 1885. A curious species. (G. C. 1885, xxiv., p. 552.)

C. globiflorum (globe-flowered). *fl.*, sepals and petals olive-brown, concave, imbricated; lip glaucous, spotted with reddish-violet within and on the outer margin, globose-hemispherical; spike elongated, many-flowered. June. Brazil, 1840. (B. M. 3942.)

C. Gnomus (Gnome). *fl.*, sepals green, spotted with purple; petals violet; lip green at base, the hood slightly dotted with red; pedicels remote. *l.* oblong-lanceolate, sheathing at base. Pseudo-bulbs whitish, oblong-ovate, attenuated at apex. Brazil, 1877. (I. H. 1877, t. 270.)

C. hymenophorum (membrane-bearing). Allied to *C. chloranthum*, but differing in the general form and colour of the flowers; sepals a little more fleshy; lip forming a pouch relatively wider and shallower. South America, 1895.

C. Imperiale (imperial). A variety of *C. splendens.*

C. Imschootianum (Imschoot's). *fl.* yellow, numerous, disposed in an erect raceme; sepals and petals tinged with green; lip saccate, fleshy, nearly truncate, folded inwards. *l.* large, plicate. Pseudo-bulbs oblong-fusiform. Brazil, 1893. (L., t. 403.)

C. Lehmanni (Lehmann's). *fl.* in a loose, drooping raceme; sepals and petals green, equal, ovate, acute, connivent in a globe; lip yellowish-flesh-colour, semi-orbicular-saccate, trilobed. *l.* narrow-lanceolate. Colombian Andes, 1886. A curious but by no means beautiful species. (R. G. 1223, a-g.)

C. Lemosii (Lemos'). *fl.* 1½in. across; sepals and petals greenish-yellow; lip light green and yellow; scape 1ft. long, erect, many-flowered. *l.* 8in. long, 2¼in. broad. Pseudo-bulbs fusiform, 6in. long. Brazil, 1894. (B. M. 7444.)

C. Lichtensteinii (Lichtenstein's). *fl.* greenish and brown. 1892. Allied to *C. Trulla.*

C. Lindeni (Linden's). A variety of *C. splendens.*

C. longifolium (long-leaved). *fl.* greenish-yellow, tipped with crimson, broadly oblong, recurved; lip yellow, tipped with crimson, galeate, having a fringed membrane under the limb. August. *l.* linear-ligulate, 1½ft. long. Demerara, 1837. A fine species. (B. M. 3019; L. S. O. t. 31; Ref. B. t. 32; W. O. A. x., t. 456.) SYN. *Monachanthus longifolius.*

Catasetum—*continued.*

C. luridum (lurid). *fl.* globose; sepals and petals spotted; lip yellowish, fleshy, hood-like, the margins purple-spotted, neither ciliated, toothed, nor inflexed; raceme nearly 1ft. long, nodding at apex, few-flowered. Stems sulcate, 3in. to 5in. long. Bahia. (B. M. 3590.)

C. macrocarpum (large-fruited). The correct name of *C. tridentatum* (B. M. 3329). *fl.* about 4in. in diameter. (B. M. 2259; I. H. xxxiii., t. 569.) SYN. *C. Claveringii* (L. B. C. 1344).

C. m. bellum (pretty). A variety having purplish-brown sepals, and a large purplish-brown blotch on either side the lip. Brazil, 1886.

C. m. carnosissimum (very fleshy). This is described as "possibly a monstrosity between the male and the female of this species." 1895. (L. xi., t. 26.)

C. m. chrysanthum (yellow-flowered). A form with bright yellow flowers. South America. (L. v., t. 197.)

C. m. Lindeni (Linden's). A variety of *C. splendens.*

C. macroglossum (large-lipped). *fl.* very variable in colour—green, yellow, and brownish-purple; sepals and the broader petals oblong-ligulate; lip saccate; raceme few-flowered. Ecuador, 1877.

C. mirabile (remarkable). A natural hybrid, resembling *C. splendens Luciani.* 1895. (L. x., t. 456.)

C. O'Brienianum (O'Brien's). A form of *C. splendens.*

C. pallidum (pale). This species differs from *C. Finetianum* chiefly in having shorter sepals and petals and a more fleshy lip. Habitat not recorded, 1894.

C. Phasma (visionary). *fl.* rather large; sepals and petals dark green, with purplish-brown spots; limb of lip white, the side lobes erect, densely serrulated; column light green, spotted with brown. Eastern Brazil, 1877. Allied to *C. Gnomus.*

C. pileatum (capped). *fl.* white, rather large; sepals narrow-oblong, acute; petals broadly oblong, acute; lip large, broadly triangular, with a bluntly conical spur; column with a very long beak. Venezuela, 1886.

C. pulchrum (pretty). *fl.* five or six in a short raceme; sepals and petals light green, barred with chocolate-brown, elliptic, acute; lip deep yellow, oblong, saccate, obscurely three-toothed at apex. Pseudo-bulbs stout, fusiform, 4in. to 6in. long, ¾in. to 1in. thick, producing the racemes from the base. Brazil, 1888. (L. iii., t. 120.)

C. punctatum (dotted). *fl.* scented, 2in. across; sepals and petals yellowish-green, spotted with brown; lip dark yellow; scape 8in. long, bearing about a dozen flowers. *l.* broadly lanceolate, 10in. long. Pseudo-bulbs fusiform, 6in. long. Brazil, 1894.

C. quornus. A misprint for *C. Gnomus.*

C. Randii (Rand's). This differs from *C. Garnettianum* mainly in the lip having a short, broad, brush-like appendage. Brazil, 1894. (B. M. 7474.)

C. revolutum (revolute). *fl.* of the same texture as in *C. splendens*; sepals and petals pale greenish-yellow; lip forming a shallower and narrower pouch than in *C. splendens.* Habitat not recorded, 1894.

C. Rodigasianum (Rodigas'). *fl.* 3in. across, in a long raceme; sepals green spotted with brown outside, almost entirely brown inside; petals green, spotted with brown; lip yellow, spotted with purplish-brown, concave, three-toothed in front. Summer. Pseudo-bulbs thick, fusiform. Santa Catharina, Brazil, 1890. (L. vi., t. 259.) The variety *tenebrosum* has much darker flowers than the type. 1894.

C. sanguineum (bloody). *fl.* greenish, speckled with brown or dull red, not at all handsome, disposed in a close raceme; sepals and petals turned upwards; lip lacerated, except at the base. October and November. *l.* light glaucous-green. Pseudo-bulbs 6in. to 7in. long. Central America, 1850.

C. s. integrale (entire). *fl.* having the anterior lip wholly entire. 1887.

C. semiroseum (half-pink). A form of *C. splendens.*

C. splendens (splendid). *fl.* approaching those of *C. Bungerothi* in both form and colour, but a little smaller; spur rather more conical, deep yellow inside. 1894. A supposed natural hybrid between *C. Bungerothi* and *C. macrocarpum.*

The following varieties have been named: *acutipetalum, albo-purpureum, album, Aliciæ, atropurpureum, aurantiacum, aureo-maculatum, aureum, flavescens, Grignani, Imperiale* (L. x., t. 460), *Lansbergianum, leucanthemum, Lindeni, Luciani, macrocarpum luteo-roseum, maculatum, O'Brienianum, regale, rubiginosum* (L. 1897, t. 555), *rubrum, semi-roseum, viride, Worthingtonianum* (L. xi., t. 14.)

C. tabulare serrulata (serrulated). *fl.* green, yellowish-white, and bluish-white, the side margins of the lip serrulated. 1886. (R. G. 1223, h-m.) Other varieties are: *brachyglossum, lævе,* and *rhinophorum.* (G. C. 1895, ii., p. 44, f. 8.)

C. tapiriceps (tapir-headed). *fl.* numerous; sepals green; petals brown; lip orange, trigono-sacciform, the free margin toothleted,

Catasetum—*continued.*
the side laciniæ revolute, the middle one with a transverse, emarginate keel not far from the margin; column resembling "a Malayan tapir, with its curved trunk." Brazil, 1888.

C. tigrinum (tiger-marked). *fl.*, sepals and petals white, the latter unusually broad, all with numerous cinnamon-coloured bars; column and lip whitish-ochre; lip thick, narrow, triangular. Habitat not recorded, 1881. A curious species, allied to *C. barbatum.*

C. tridentatum. The correct name is *C. macrocarpum.*

C. trifidum (thrice-cleft). *fl.* greenish, dotted with purple, 1½in. long; sepals and petals converging from a spreading base; lip trifid; raceme drooping. June. *l.* oblong-lanceolate, shortly acuminate. Trinidad. (B. M. 3262.)

C. Trulla (trowel-shaped). *fl.* green and brown; sepals and petals spreading, oval, flat; lip much the shape of a trowel, not at all hollowed out into a bag, but merely concave like the bowl of a spoon, the edges fringed; column short, tendrilled. September. Tropical America, 1840. (B. R. xxvii. 34.)

C. T. maculatissimum (much-spotted). *fl.*, sepals, petals, and the anterior part of the sides of the column covered with brown spots; anterior side of the lateral lobes of the lip having well-developed fringes. 1888.

C. T. subimberbe (almost beardless). In this variety the lip is practically beardless. 1887.

C. uncatum (hooked). *fl.* green, numerous, disposed in an erect raceme. *l.* lanceolate, 1ft. long. Pseudo-bulbs fusiform, 3in. to 8in. long. Brazil, 1895.

C. viridi-flavum (green and yellow). *fl.* green; sepals and petals concave; lip marked with yellow on the inside, somewhat conical-saccate, hooded. Summer. *l.* oblong, acute. Central America, 1841. (B. M. 4017.)

The following have also been introduced: *C. incurvum* (SYN. *C. stupendum*), *C. mentosum*, *C. Oerstedii*, *C. triodon.*

CAT BERRY. *See* **Ribes Grossularia.**

CATCHFLY, GERMAN. *See* **Lychnis Viscaria.**

CATERPILLAR. This word is generally limited to the larval state of Lepidopterous insects (Moths and Butterflies). A Caterpillar is made up of a head and thirteen segments or body divisions. There are usually three pairs of thoracic legs and a variable number of what entomologists call abdominal feet. These latter are situate upon the hinder divisions of the body, and are variable in number. The latter pair of abdominal feet are modified for clasping. Abdominal feet are of temporary use, and finally are absorbed. The six thoracic legs are a practically constant feature in Lepidopterous larvæ, but there are a few isolated cases in which they are altogether wanting. In the changes which take place they are eventually employed in the production of the legs of the perfect insect.

CATERPILLAR PLANT. *See* **Scorpiurus.**

CATHA. *Methyscophyllum* and *Trigonotheca* are synonymous with this genus.

CATHA (of Endlicher). A synonym of **Gymnosporia** (which *see*).

CATHARANTHUS. Included under **Vinca** (which *see*).

CATHEA. A synonym of **Calopogon** (which *see*).

CATIMBIUM. A synonym of **Alpinia** (which *see*).

CAT-O'-NINE-TAILS. *See* **Typha latifolia.**

CATOPSIS. SYNS. *Pogospermum*, *Tussacia.* This genus embraces about fifteen species, natives of tropical America. Sepals and petals free to the base, the latter white or yellow; stamens shorter than the calyx; spikes simple or panicled. Leaves lorate or lanceolate, thin, nearly naked. The species (all of which are closely allied) are not much known in cultivation.

CAT'S-EAR. *See* **Antennaria.**

CATTERIDGE-TREE. *See* **Euonymus europæus.**

CATTLEYA. The species of this genus are all natives of the warmer parts of America, from Brazil to

Cattleya—*continued.*
Mexico. The following corrections of, and additions to, the information given on pp. 280-4, Vol. I., are based upon the monograph of the genus by Messrs. James Veitch and Sons, in Part II. of their "Manual of Orchidaceous Plants," and embrace the most recent introductions, but do not include the hosts of minor varieties that are never likely to be generally grown, or that are scarcely distinguishable from the typical plants. A list of the garden hybrids is appended.

C. Alexandræ (Alexandra's). A synonym of *C. elongata.*

C. amabilis (lovely). A synonym of *C. intermedia.*

C. amethystina (amethystine). A synonym of *A. intermedia.*

C. aurantiaca (orange). The correct name of *Epidendrum aurantiacum.*

C. aurea (golden). A variety of *C. Dowiana.*

C. autumnalis (autumnal). A garden synonym of *C. Bowringiana.*

C. bicolor Measuresiana (Measures'). A pretty variety, having the lip bordered with white. 1888. (W. O. A. 357.)

C. b. Wrigleyiana (Wrigley's). *fl.*, sepals and petals greyish-green; lip dark purple. 1885.

C. Bluntii (Blunt's). A form of *C. Mendelii.*

C. bogotensis (Bogota). A synonym of *C. Trianæi.*

C. Boissieri (Boissier's). *fl.*, sepals and petals soft rosy-lilac; lip broad, with a beautiful, curving, yellow blotch extending halfway down and nearly across it. *l.* oblong, short and broad. Colombia.

C. Bowringiana (Bowring's). *fl.* rich rosy-purple, about 2½in. in diameter, the front of the lip deep purple, with a transverse, maroon band, behind which the tube is whitish; raceme corymbose, five- to ten-flowered. Autumn. Central America, 1886. A charming species, allied to *C. Skinnieri.* SYN. *C. autumnalis* (of gardens). (J. H. 1886, xii., p. 397, f. 71-2; R., ser. ii., i., t. 2; R. H. 1890, p. 300; W. O. A. vii., t. 323.)

C. Brownii (Brown's). *fl.* about 4in. in diameter, five or more in a raceme; sepals and petals bright rose-purple, undulated; lip pale purple, three-lobed, with some darker veins. *l.* oblong, coriaceous. Pseudo-bulbs 2ft. high, two-leaved. Habitat not recorded, 1893.

C. bulbosa (bulbous). A synonym of *C. Walkeriana.*

C. candida (white). *fl.*, sepals and petals white, shaded pink; lip the same colour, with a dash of yellow in the centre; spike three- or four-flowered. July to November. *h.* 1ft. Brazil Allied to *C. intermedia.*

C. chocoënsis. This is now regarded as a variety of *C. Trianæi.*

C. coccinea (scarlet). A synonym of *Sophronitis grandiflora.*

C. crispa. This is now classed under *Lælia.*

C. dolosa. This is now regarded as a variety of *C. Walkeriana.*

C. Dormaniana (Dorman's). The correct name of *Lælia Dormaniana.* (W. O. A. 401.)

C. Dowiana. This is now regarded as a variety of *C. labiata.*

C. D. aurea (golden). *fl.* very large; sepals and petals pale yellow; lip rich, deep purple, veined with yellow. Colombia, 1883. A gorgeous variety. (W. O. A. 84.) SYN. *C. aurea* (I. H. 493).

C. Edithiana (Edith's). *fl.* 6in. to 7in. in diameter; sepals and petals light mauve; lip white, striped mauve, the disk buff. *l.* dark green. *h.* 1ft. Brazil. Habit like *C. Mossiæ.*

C. Eldorado. This is now regarded as a variety of *C. labiata.*

C. E. crocata (saffron-coloured). *fl.* broad, white, with a broad, deep orange line running from the base of the lip on the anterior disk, where it expands into a pentagonal blotch, with teeth in front. 1885.

C. E. Oweni (Owen's). *fl.* white; lip having a yellow blotch and a band of rosy-crimson. 1894. (L., t. 409.)

C. E. virginalis (virgin-white). *fl.* sweet-scented; sepals and petals snow-white, the former lanceolate, acute, the latter broad, elliptic, obtuse; lip white, with a yellow disk and tube, entire, with a frilled front lobe. August and September. Amazon Country. SYN. *C. virginalis* (I. H. ser. iii. 257). The form *rosea* has a distinct, rosy-purple blotch on the front of the anterior portion of the lip.

C. E. Wallisii (Wallis'). *fl.*, segments white, the orange-yellow disk of the lip reduced in size.

C. elegans (elegant). A synonym of *Lælia elegans.*

C. elongata (elongated).* *fl.*, sepals and petals clear green, spotted with rich brown and tinted with violet on the margin, 2in. long, ½in. broad; lip rosy-violet; peduncles 1½ft. to 1½ft. long. Autumn. Pseudo-bulbs cylindrical, 1ft. to 1½ft. long. Brazil,

Cattleya—*continued.*

1892. Allied to *C. guttata Leopoldi.* (B. M. 7543.) SYN. *C. Alexandræ* (L. viii., t. 358).

C. felix (fruitful). A synonym of *Lælia felix.*

C. floribunda (abundant-flowered). *fl.* carmine, white, or variously coloured; scapes long, bearing about a score of flowers. Habitat not recorded, 1895. Described as possibly a natural hybrid between *C. maxima* and *C. labiata.*

FIG. 215. FLOWER OF CATTLEYA FORBESI.

C. Forbesi (Forbes'). *fl.* 3in. to 4in. in diameter; sepals and petals pale yellowish-green, sub-equal; lip three-lobed, the two lateral lobes yellow, sometimes streaked red, convolute over the column, the middle lobe pale yellow, with a broad, bright yellow, central band; column yellow, spotted and stained red; peduncles erect, two- to five-flowered. *l.* ovate-oblong, coriaceous. Stems about 1ft. high, two-leaved. Rio de Janeiro, 1823. (B. M. 3265; B. R. 953.) See Fig. 215.

C. Gaskelliana (Gaskell's). A variety of *C. labiata.*

C. gigas. This is now regarded as a variety of *C. Warscewiczii.*

C. granulosa asperata (rough). *fl.*, sepals and petals brownish, spotted dark purple; lip yellowish at base, light vivid purple with a broad white border in front, rough. 1886.

C. g. Banneri (Banner's). *fl.* about 6in. across; sepals and petals suffused with bright lurid purple. 1896.

C. g. Buyssoniana (Buysson's). *fl.* having the sepals and petals ivory-white. 1890. (G. C. 1890, viii., p. 588, f. 116; L., t. 270.)

C. g. Schofieldiana (Schofield's). *fl.*, sepals and petals greenish-yellow, spotted with crimson, the petals narrow at the base, very broad and obtuse at the apex; lip rich purple, with whitish side lobes, the middle lobe covered with lamellæ and papillæ. *l.* broad, two to a pseudo-bulb. Pseudo-bulbs 1½ft. high. SYN. *C. Schofieldiana* (W. O. A. ii. 93).

C. guttata immaculata (unspotted). *fl.*, sepals and petals mauve-brown, without spots; lip white, the front lobe purple. 1886. Of *C. g. Leopoldii* (shown in Fig. 216) there is a Heliotrope-scented form, *odoratissima.*

C. g. leopardina (leopard-spotted). *fl.* numerous and handsome; sepals and petals thickly spotted with dark brown; side lobes of the lip white, the broad, bilobed, front lobe rich purplish-red; racemes large. Pseudo-bulbs elongated. 1886.

C. g. Prinzii (Prinz'). A synonym of *C. amethystoglossa.*

C. Harrisoniæ (Mrs. Harrison's). This is now regarded as a variety of *C. Loddigesii.*

C. Holfordi (Holford's). A garden synonym of *C. luteola.*

C. imperialis (imperial). A synonym of *C. Warscewiczii.*

C. intermedia candida splendens (white, splendid). *fl.* pure white except the front lobe of the lip, which is carmine-purple. Rio Janeiro, 1890. (R. G. 1890, t. 1313.) *Parthenia* is another white-flowered form, and *Gibeziæ* (L. iii., t. 133) has similar blossoms with three orange lines on the disk. See Fig. 217.

C. iricolor (rainbow-coloured). *fl.* milk-white, with a few purple marks on the lip, 3in. to 4in. across; petals narrower than the sepals; lip obscurely three-lobed, the two lateral lobes convolute over the column; peduncles two- or three-flowered. *l.* 1ft. long, strap-like, complicate at base, emarginate at apex. Stems 4in. to 5in. long, one-leaved. Native country unknown.

Cattleya—*continued.*

FIG. 216. FLOWER OF CATTLEYA GUTTATA LEOPOLDII.

C. Kimballiana (Kimball's) *fl.* large; sepals and petals of a delicate rosy-white, the former lanceolate, acute, the latter very broad, elliptic, wavy; tube of the lip white outside, with some yellow near the front margins, the inside yellow with some orange lines, the wavy front lobe rich purple on the front part. Venezuela, 1881. A fine species.

C. labiata. The following are now included here as varieties: *Dowiana, Eldorado, gigas, Luddemanniana, Mendelii, Mossiæ, Percivaliana, Trianæi, Warneri,* and *Warscewiczii.*

FIG. 217 FLOWER OF CATTLEYA INTERMEDIA CANDIDA SPLENDENS.

Cattleya—*continued.*

C. l. Gaskelliana (Gaskell's). *fl.* 7in. across, resembling those of *C. Mossiæ*, but paler; lobes of the lip confluent, crisped, yellow within. Autumn. Brazil. A magnificent plant. (I. H. 1886, t. 613, under name of *C. Gaskelliana.*) The form *alba* has white flowers with a yellow throat.

C. Lawrenceana (Sir Trevor Lawrence's). *fl.* purplish-lilac, as large as those of a good *C. Trianæi*; sepals uncommonly broad; petals broader than the sepals, usually blunt; lip pandurate, emarginate, rather broader in front than at the base; the anterior part of the darkest, warmest purple, the side wings purple, the centre light yellow. British Guiana, 1885. A fine species. (B. M. 7133; G. C. n. s., xxiii., pp. 374-5; L., t. 44.)

C. L. concolor (one-coloured). *fl.* wholly of a light purple. 1886.

C. Leopoldii (Leopold's). A variety of *C. guttata.*

C. Lindleyana. This is now classed under *Lælia.*

C. lobata. This is now classed under *Lælia.*

C. Loddigesii candida (white). *fl.* white, with a yellow disk to the lip.

Cattleya—*continued.*

C. L. Harrisoniæ (Mrs. Harrison's). The correct name of *C. Harrisoniæ.*

C. L. violacea (violet). *fl.* more deeply coloured than in the type.

C. Luddemanniana (Luddemann's). *fl.*, sepals and petals delicate purplish-rose; suffused white, the petals nearly three times as broad as the sepals, and gently undulated, chiefly in the distal half; convolute lobes of the lip of the same colour externally as the sepals and petals, the anterior lobe fine amethyst-purple, crisped, emarginate, with two pale yellow or white blotches at the entrance of the tube, between which are lines of amethyst-purple gently diverging from the base of the lip. September and October. This is a variety of *C. labiata.* SYN. *C. speciosissima.* See Fig. 218.

FIG. 218. FLOWER OF CATTLEYA LUDDEMANNIANA.

C. L. alba (white). *fl.* large, pure white, with a pale yellow stain on the disk of the lip. Also called *Sanderiana.*

C. luteola (yellowish). *fl.* yellow, 2in. across; sepals narrow-oval, blunt; lip white, with a yellow disk, cucullate, rounded and crenulate, velvety inside. Pseudo-bulbs oval, ancipitous, one-leaved. Brazil. (B. M. 5032; R. X. O. i. 83.) SYN. *C. Holfordi* (of gardens).

Cattleya—*continued.*

FIG. 219. FLOWER OF CATTLEYA MENDELII.

C. marginata. This is now regarded as synonymous with *Lælia pumila.*

C. maxima alba (white). *fl.* white, having the usual yellow and purple markings on the lip.

C. Mendelii. This is now regarded as a variety of *C. labiata.* See Fig. 219.

C. M. Bluntii (Blunt's). *fl.* white; lip stained yellow in the throat.

C. M. Kegeljani (Kegeljan's). *fl.* white except the disk of the lip, which is striped and shaded with sulphur-yellow. 1897 (L. 1897, t. 589.)

C. Mossiæ. This is now regarded as a variety of *C. labiata.*

C. M. Reineckiana (Reinecke's). *fl.*, sepals and petals pure white; lip having an orange disk, and rays of violet lines and dots towards the margin. 1884. See Fig. 220.

C. M. Wageneri (Wagener's). The correct name of *C. Wageneri.*

C. nobilior. This is now regarded as a variety of *C. Walkeriana.*

C. Obrieniana (O'Brien's). This closely resembles *C. Loddigesii* (of which it is sometimes classed as a variety), but the flowers are paler and the lateral lobes of the lip are shorter and smaller than in that species. Brazil. (R. ser. ii., t. 40, under name of *C. Loddigesii O'Brieniana.*)

C. Oweniana (Owen's). A form of *C. labiata.*

C. Percivaliana (Percival's). *fl.* smaller than in *C. Mossiæ*, but darker and richer in colour in the best forms; sepals and petals deep blush; lip intense magenta-crimson, margined with blush-pink, much fringed, the throat marked with golden and crimson lines. January and February. Colombia. A distinct form of *C. labiata.* (Gn., 1889, xxxv., p. 532; G. C. n. s., xxi., p. 178; R. i., t. 2; W. O. A. iii. 144.)

Cattleya—*continued.*

C. P. alba (white). *fl.*, sepals and petals pure white; lip white, with an orange stain in the throat. Brazil, 1834.

C. Pinelii (Pinel's). A synonym of *Lælia pumila præstans.*

C. porphyroglossa (purple-tongued). *fl.*, sepals and petals of a light chestnut-brown; lip very fine, the stalk of the anterior lacinia crenulated or serrated at the edges, the central lacinia much keeled; column white at back, yellow covered with purple stripes in front. Brazil, 1837. This species resembles *C. guttata*, but has larger flowers. (R. X. O., ii., t. 171, f. 1, t. 172, f. 2.)

C. pumila. This is now regarded as synonymous with *Lælia pumila.*

C. Regnelli. This is now regarded as synonymous with *C. Schilleriana.*

C. Reineckiana (Reinecke's). A variety of *C. Mossiæ.*

C. Rex (King). *fl.*, sepals white, tinged with primrose-yellow, 3½in. long; petals creamy-white, 3½in. long, wavy-edged; lip white, yellow, and red, the column white. Habitat not recorded. 1890. Probably a form of *C. Dowiana aurea.* (G. C. 1891, ix., p. 273, f. 61; J. H. 1892, p. 170, f. 24; L. vi., t. 265.)

C. Rollissonii (Rollisson's). A synonym of *C. Trianæi delicata.*

C. Sanderiana (Sander's). A synonym of *C. Warscewiczii.*

C. Schilleriana Lowii (Low's). *fl.* of a pleasing lavender-blue; lip streaked with a darker shade of the same colour. 1892. (J. H. 1892, p. 187, f. 26.)

C. Schofieldiana (Schofield's). A variety of *C. granulosa.*

C. Schrœderæ (Baroness von Schrœder's). *fl.* generally very light purple, exquisitely perfumed, easily distinguishable from *C. Trianæi* by the extraordinary crispation of both petals and lip, and by the well-known orange area of the lip reaching far nearer the apex. 1887.

C. Skinneri alba (white). A variety with pure white flowers. (W. O. A. iii., t. 112.)

C. S. parviflora (small-flowered). *fl.* half the size of those of the type; lip whole-coloured, not pallid over the lower half. (B. M. 4916.) The following are sub-varieties: *alba*, snow-white, with a small primrose blotch on the lip, and, occasionally, some mauve-purple markings at the base (W. O. A. iii. 112); *oculata*, with a large, maroon-purple blotch on the lip.

C. speciosissima (very showy). A synonym of *C. Luddemanniana.*

C. suavior (sweeter). *fl.*, sepals and petals pale rosy-lilac, suffused white; side lobes of the lip white, tinted pale lilac towards the margins; middle lobe amethyst-purple, with a crisped margin and a deep sinus or cleft in the anterior margin; disk creamy

FIG. 220. FLOWER OF CATTLEYA MOSSIÆ REINECKIANA.

Cattleya—*continued.*

FIG. 221. FLOWER OF CATTLEYA SUPERBA ALBA.

white, a purple band extending below it to the base. A natural hybrid between *C. intermedia* and *C. Mendelii.*

C. superba alba (white). A beautiful variety with pure white flowers. 1890. See Fig. 221.

C. Trianæi [the correct spelling]. This is now regarded as a variety of *C. labiata.*

C. T. alba (white). *fl.* white, with the usual yellow disk of the lip, in front of which is a small blotch varying in colour from rosy-purple to pale-lilac.

C. T. Backhousiana (Backhouse's). *fl.* very large; sepals and petals blush-pink; lip large, with a bright magenta stain on the anterior part, the throat marked pale yellow.

C. T. chocoënsis (Choco). The correct name of *C. chocoënsis.*

C. T. delicata (delicate). *fl.* 6in. across; sepals and petals white; lip large, with a beautiful yellow centre and a tinge of rose, white outside. December and January. *h.* 1ft. Brazil, 1861. SYNS. *C. Rollissonii* (F. M. 1861, 8), *C. Warscewiczii delicata* (W. S. O i. 4). *superba* is a fine variety, with a very large lip.

FIG. 222. FLOWER OF CATTLEYA WALKERIANA.

Cattleya—*continued.*

C. T. Leeana (Lee's). *fl.* about 7in. in diameter; sepals and petals rosy-lilac, 3in. across; lip deep magenta-mauve; faintly margined lilac-rose, 2in. in diameter in the fore part; throat striped orange, very large and open.

C. T. rosea (rosy). *fl.*, sepals and petals rose-coloured; lip bright rosy-lilac, with a yellow blotch at the mouth of the throat.

C. velutina (velvety). *fl.* very fragrant; sepals and petals pale orange, spotted and streaked purple; lip orange at base, white with violet veins in front, where the surface is velvety. Brazil. The habit of this supposed natural hybrid closely resembles that of *C. bicolor.* (G. C. 1872, p. 1259; R. G. 1888, t. 1265; W. O. A., i., t. 26.)

C. virginalis (virgin-white). A form of *C. Eldorado.*

C. Wageneri (Wagener's). This is now regarded as a variety of *C. Mossiæ.*

C. Walkeriana. SYN. *C. bulbosa.* In addition to *C. Schrœderiana, C. dolosa* and *C. nobilior* are now regarded as forms of this species. See Fig. 222.

C. Wallisii (Wallis'). A form of *C. Eldorado.*

C. Warneri. This is now regarded as a variety of *C. labiata.*

C. Warscewiczii. This is now regarded as a variety of *C. labiata.* SYN. *C. Sanderiana.*

C. W. delicata (delicate). A synonym of *C. Trianæi delicata.*

C. W. franconvillensis (Franconville). *fl.* pure white with the exception of a purplish-crimson blotch on the lip. 1893. (W. O. A., t. 505).

Though practically no new species of *Cattleya* have been introduced since the original volumes were issued, we have to record as worthy of note the reintroduction (after its habitat had been practically lost for forty years) of the true autumn-flowering variety of *C. labiata.* It is now one of the most abundant and useful of the genus. With the increased numbers of this lovely variety, many choice and desirable forms have appeared, varying from pure white to depths of colour unknown in any other Cattleya.

To the work of the hybridist we turn with pleasure, and note the vast strides that have been made. The increase in variety which has been obtained by the intercrossing of the various species of Cattleyas has been little short of remarkable. Hybrid Cattleyas, during the past five years, have increased more than fifty per cent. The increase of the bigeneric hybrids (a list of which is given under Lælio-Cattleyas) have increased rather more than eighty-five per cent. during that period. One of the greatest advantages that have been gained by the intercrossing of the species is that the offspring from such usually flowers at periods intermediate between the parent species. For example, an autumn-flowering species crossed with one of the summer-flowering ones, in the majority of cases produces a winter-flowering offspring. So that by careful selection it is now possible to obtain a succession of plants flowering throughout the year.

For the guidance of those interested in the raising of seedlings, and as an assistance to their nomenclature, we append a list of hybrids, with their recorded parentage. It includes practically all the varieties that have been introduced up to date. In addition to the Lælio-Cattleyas already noted, there will be other bigeneric hybrids, such as Sophro-Cattleyas, Epi-Cattleyas, Epiphronites, &c., under which the offspring of such crosses will be found.

Aclandi-Loddigesii	*Loddigesii* and *Aclandiæ* (Veitch).
Adela	*Trianæi* and *Percivaliana* (Veitch).
Alberta	*Loddigesii* and *superba* (Imschoot).
Alberti	Syn. *porphyrophlebia* (Bleu).

weedonensis	*Mendelii* and *granulosa* (Thornton).
Wendlandiana	*Bowringiana* and *Warscewiczii* (Veitch).
William Murray	*Mendelii* and *Lawrenceana* (Cookson).
Wilsonii	*bicolor* and *guttata* (Wilson).

The following are Natural Hybrids:

Aurora	*Regnierii* and *rosea*.
Barberiana	*vestita* and *Turnerii*.
Battalinii	*intermedia* and *bicolor*.
Brymeriana	*Eldorado* and *superba*.
Cupido	*Schrœderæ* and *Mendelii*.
Czar	*labiata vera* and *granulosa*.
Eyermanni	*vestita* and *Veitchii*.
flaveola	*intermedia* and *guttata*.
Hardyana	*Warscewiczii* and *Dowiana aurea*.
Imperator	Syn. *Czar*.
intermedio-Loddigesii	*intermedia* and *Loddigesii*.
intricata	*guttata* and *intermedia*.
Krameriana	*intermedia* and *Forbesii*.
Laucheana	*Sanderiana* and *veratrifolia* (Sander).
linliginosa	*labrosa* and *Veitchii*.
Lowryana	*intermedia* and *Forbesii*.
Lucieniana	*Forbesii* and *guttata*.
Massaiana	*Hardyana* var.
Measuresiana	*Aclandiæ* and *Walkeriana*.
Patrocinii	*Loddigesii* and *Leopoldii*.
resplendens	*granulosa* and *Schilleriana*.
scita	*guttata* and *intermedia*.
sororia	*Walkeriana* and *guttata*.
venosa	*Harrisoniæ* and *Forbesii*.
Victoria Regina	*guttata* and *labiata*.
Whiteii	*labiata* and *Schilleriana*.

CATTLEYA FLY (*Isosoma orchidearum*). This insect deposits its eggs in the eye of the young growth when the plant is in a dormant state. As a consequence, the growth does not advance much above 1in., swells in the centre, and generally exhibits a stunted appearance. If this growth is cut off at the base and split open, there will be disclosed from three to seven yellowish maggot-like creatures. After eating a large hole in the young growth, they become pupæ, and eventually emerge as perfect flies. They should be destroyed as soon as seen. Fumigation with a vaporising insecticide will effectually settle them before they have time to deposit their eggs. The roots, too, not infrequently, are pierced by the insects, and a warty growth results. The grubs should be picked out with a stout needle.

CAT WHIN. *See* **Ulex nanus.**

CAUCASIAN WALNUT. *See* **Pterocarya fraxinifolia.**

CAULIFLOWER DISEASE OF STRAWBERRY. A name applied to a most injurious disease caused by the minute animals known as Eelworms, or Nematoid Worms. *See* **Strawberry.**

CAULIFLOWERS. For autumn sowing the best are: Early London, Eclipse, Dwarf Erfurt, and Veitch's Autumn Giant. The last-named is a most reliable variety, as it never fails to form good heads the following summer, even in the hottest weather, when other varieties are failures in that respect. For spring sowing all those previously mentioned are valuable, as are also Early Snowball, First Crop, Dwarf Mammoth, and Walcheren.

CAUTLEYA (named in honour of Major-General Sir P. Cautley, F.G.S., 1802-1871, joint author, with Dr. Falconer, of the "Fauna antiqua sivalensis"). ORD. *Scitaminea*. A monotypic genus, included by some authorities under *Roscoea*. The species is a stove, perennial herb, requiring similar treatment to **Alpinia** (which *see*).

C. lutea (yellow). *fl.* 1½in. to 2in. long; calyx red-purple, tubular, two-cleft at mouth; sepals linear-oblong, obtuse, concave, the dorsal one erect, the lateral ones reflexed; corolla golden-yellow, the tube exserted; lateral staminode like the dorsal sepal, erect, the tips incurved; spike 4in. to 8in. high. August. *l.* 5in. to 10in. long, narrow-lanceolate, with a slender tip, bright green above, paler or suffused or streaked red-brown beneath. Stems 8in. to 18in. high, tufted, erect, leafy. Himalaya, 1837. (B. M. 6991.) SYNS. *Roscoea gracilis, R. lutea.*

CAVENDISHIA. This is now the correct name of **Proclesia** (which *see*), according to Bentham and Hooker. To the species described on p. 225, Vol. III., the following should be added:

C. spectabilis (showy). *fl.* white, shaded with pink, tubular, slightly swollen below, when in bud covered with rosy-carmine bracts; racemes compressed. *l.* oblong, acuminate, bright reddish-bronze when young, changing to bright green. Colombia, 1889. A handsome, somewhat climbing shrub.

CEANOTHUS. This genus embraces about twenty-eight species, all North American. To those described on p. 285, Vol. I., the following should be added:

C. americanus variegatus (variegated). A garden variety, having the leaves bordered with yellow. 1889.

C. axillaris (axillary). *fl.* pale lilac tinged with rose, in axillary and terminal thyrses. Summer. *l.* ovate-lanceolate, rounded-obtuse, dark green above, white-tomentose beneath. 1876. A form of *C. azureus*. (R. H. 1876, f. 14.)

C. Baumannianus (Baumann's). A synonym of *C. microphyllus*.

C. Delilianus (Delile's). This differs from *C. azureus* in having flowers of a paler blue, and larger leaves lightly pubescent beneath. Origin unknown. SYN. *C. pulchellus*.

C. elegans (elegant). A synonym of *C. thyrsiflorus*.

C. Fendleri (Fendler's). *fl.* snow-white, disposed in short, terminal racemes. *l.* varying from narrowly oblong to elliptic, ¼in. to 1in. long, somewhat narrowed and cuneate at base, obtuse or acute at apex, dark glossy green above, silky below. Colorado, 1893. A half-hardy, much-branched, thorny bush. *C. Fenolleri* is apparently a misprint for *C. Fendleri*.

C. Fenolleri. *See* **C. Fendleri.**

C. Fontanesianus (Fontanes'). A synonym of *C. ovatus*.

C. laniger (wool-bearing). A synonym of *Pomaderris lanigera*.

C. ovalis (oval). A synonym of *C. ovatus*.

C. ovatus (ovate). *fl.* usually on short peduncles. *l.* narrowly oval or elliptic-lanceolate, 1in. to 2in. long. *h.* 2ft. to 3ft. Otherwise like *C. americanus*. Texas, &c., 1888. Hardy. SYNS. *C. Fontanesianus, C. ovalis.*

C. prostratus (prostrate). *fl.* bright blue, in axillary clusters, borne on stout peduncles. *l.* ¼in. to 1in. long, obovate or oblong-cuneate, spinose usually only at the apex, one-ribbed, very thick, borne on short, slender petioles. Oregon, 1889. A hardy, prostrate, nearly glabrous shrub.

C. pulchellus (rather pretty). A synonym of *C. Delilianus*.

C. thyrsiflorus (thyrse-flowered). *fl.* bright blue, in dense, sub-compound panicles, terminating the usually elongated and somewhat leafy peduncles. *l.* oblong to oblong-ovate, 1in. to 1½in. long, rather thick, usually smooth and shining above, canescent beneath, glandular-serrulated. Branches strongly angled. California, 1861. A hardy, tall shrub or small tree. (G. C. 1896, ii., p. 363, f. 75.) SYN. *C. elegans* (I. H. 1860, t. 268).

CEBATHA. A synonym of **Cocculus** (which *see*).

CECIDOMYIA, or GALL MIDGES. ORD. *Diptera.* This is a genus of delicate-looking flies, whose wings contain very few nervures. The majority of the larvæ live in plants. Some are responsible for the peculiar Gall formations found upon the foliage of Limes, Willows, and many other trees; others deform the roots, the buds, the flowers, or even the stems. Yet others produce no Galls, but are destructive by living upon cereals, after the manner of the wheat pest known as the Hessian Fly (*Cecidomyia destructor*), which causes such widespread injury to cereal and grass crops in America and in Europe. It is only since 1886 that it has been regarded as a British insect. The name Hessian Fly was bestowed upon the insect by Americans, who suggested that it was introduced into that country with the straw used by the Hessian troops in 1778. The larvæ of certain species are remarkable as possessing a curious horny appendage upon the under-surface known as the breast-bone or anchor-process, the exact use of which is not known. Besides the injurious species there are others which may be considered beneficial, as they are carnivorous, feeding upon Aphides and Mites.

CECROPIA. Nearly forty species have been referred to this genus, but, according to the authors of the "Genera Plantarum," this number might be considerably reduced; they inhabit tropical America, from Brazil to Mexico. Flowers dicœcious, in numerous, very dense, cylindrical spikes on a common, axillary peduncle; male spikes thick; females slenderer. Fruit oblong, included in the very slender perianth. Leaves alternate, long-petiolate, large, peltate. To the species described on p. 285, Vol. I., the following should be added:

C. dealbata (whitened). *l.* large, soft, pubescent, palmate, light green above, glaucous beneath. Colombia, 1837. A fine Snake-wood, of ornamental character.

C. frigida is rare in cultivation.

CEDAR, PRICKLY. *See* **Cyathodes acerosa.**

CEDAR, SHARP. *See* **Acacia oxycedrus** and **Juniperus oxycedrus.**

CEDRUS. According to Sir J. D. Hooker, this genus is monotypic, with three marked forms, one (*C. Libani*, the typical form) Oriental, another (*C. atlantica*) Algerian, and the third (*C. Deodara*) Himalayan.

As the variegated forms cannot be depended upon to reproduce themselves from seed, propagation by artificial means must be adopted. The common Cedars form suitable stocks upon which to graft the ornamental varieties. The Larch, too, may be used as a stock, but it is inferior to the Cedars. In its early stages the Larch is very vigorous in growth, but with age plants that have been worked upon it present a rather unsightly appearance. Side-grafting is easy and effective. February is the best month for the operation. The scions should be taken from healthy trees and plunged in a warm (not too close) propagating-case, and shaded from the sun. When they have made a few inches of growth they should be hardened off, and kept growing in pots until they are planted out the following spring. A neat stake should be placed against each plant, and the leader secured to it. If the side-shoots grow too vigorously, they may be shortened a bit, in order to concentrate all the energies into the principal growth.

To the information given on pp. 285-7, Vol. I., the following should be added:

C. atlantica aurea (golden). A variety with golden leaves. It is constant. 1897. The typical species is shown in Fig. 223.

C. a. fastigiata (pyramidal). A garden shrub or tree of pyramidal habit, with ascending branches. 1890. (R. H. 1890, p. 32, f. 9.)

C. a. glauca (bluish-green). In this variety the leaves are of a glaucous-silvery hue, being thus very distinct from the deep green of the normal form.

C. a. pendula (pendulous). A drooping form.

Other varieties are: *aurea, columnaris, pyramidalis*, and *variegata.*

C. Deodara. Other varieties are: *aurea, compacta, crassifolia* (leaves short and stout, less ornamental than the type), *Hugeli, uncinata, variegata, viridis*, and *Youngi.*

C. Libani decidua (deciduous). This only differs from the type in partially shedding its leaves during autumn.

C. L. pendula (pendulous). A variety with gracefully pendent branches. Other varieties are: *denudata, fastigiata, glauca, pendula, hybrida, pyramidata, stricta*, and *viridis.*

CEIBA. A synonym of **Eriodendron** (which *see*).

CELANDINE POPPY. *See* **Stylophorum diphyllum.**

CELANDINE, TREE. *See* **Bocconia frutescens.**

CELASTRUS. Including *Orixa*. This genus embraces about fifteen species, natives of tropical Asia, China, Japan, Australia, and North America. To those described on p. 287, Vol. I., the following should be added:

C. articulatus (jointed). *fl.* green, with yellow anthers, about ⅛in. broad, in short, axillary, few-flowered cymes. June. *fr.*, capsule pea-like, brown, three-valved; valves golden-yellow within, at length reflexed, exposing the seeds in a shining, scarlet aril; November. *l.* petiolate, 3in. to 5in. long, oblong-oval or sub-orbicular, acute; petioles ¼in. to ½in. long. *h.* 15ft. Eastern Asia, 1891. A rambling, hardy shrub, suitable for the seaside. (B. M. 7599; G. C. 1898, i., p. 28, f. 11.)

C. cassinoides. The correct name is *Gymnosporia cassinoides*.

C. Orixa (Orixa). *fl.* green, small; males racemose; females long-stalked, generally solitary. Summer. *l.* elliptic or obovate, with entire margins; upper surface glossy-green. *h.* 6ft. to 9ft. Japan, 1836. SYN. *Orixa japonica* (R. G. 1232).

C. Pyracanthus (Pyracanthus). A synonym of *Putterlickia Pyracantha*.

FIG. 223. CEDRUS ATLANTICA.

CELERY. If required for exhibition, this vegetable should receive copious supplies of weak liquid manure, with an occasional application of nitrate of soda (1oz. in 4galls. of water is sufficient). To ensure nicely-blanched growth most exhibitors wrap the plants in double or treble folds of stout brown paper.

By Permission of the Board of Agriculture.

FIG. 224. CELERY FLY (*Tephritis onopordinis*).

1, Fly, magnified; 2, Larva, magnified; 3, Pupa, natural size.

Sorts. White varieties are usually deficient in flavour, and are only useful when the vegetable is required early or for soups. The best flavoured are Sutton's White Gem, Sandringham White, and Incomparable Dwarf White. The pink or red varieties are crisp in flavour, and also keep longer and sounder than the white sorts. Some of the best sorts are Leicester Red, Major Clarke Red, Williams's Matchless Red, Wright's Grove Red and Wright's Grove Pink, Standard-Bearer, Nonsuch Pink, and Sulham Prize Pink. These are all hardy varieties of good quality. None of the so-called self-blanching varieties are what their name indicates, and few, if any, gardeners consider them worth growing.

CELERY FLY (*Tephritis onopordinis*). Popularly this is associated with the Celery only, but it is equally as destructive to Parsnips (on whose foliage the large blisters caused by the leaf-mining pests are very familiar). The fly (Fig. 224) is ½in. in wing expanse, and yellowish brown, with rusty-coloured spots. The female deposits the eggs upon the foliage, and from these hatch out thick-bodied, legless, green maggots, slightly pointed at the head, and when full-grown about ¼in. long. There are two or three broods in a season.

As stated in Vol. I., the best way of dealing with the pest in the case of small gardens is by crushing the grub between finger and thumb; but where large areas are under cultivation this is impossible. Spraying with weak kerosene emulsion should then be adopted. In either case all leaves should be destroyed by burning when the crop is lifted, and not put on the manure-heap. Quicklime should also be incorporated with the soil.

CELERY STEM FLY. This insect, described in Vol. III. under its scientific name of *Piophila apii*, proves very troublesome in some seasons, the maggots tunnelling the stems and causing them to rot. There is more than one generation, and though in the earliest the pupal state is passed in the soil, as suggested in the volume above referred to, in the later ones it is assumed in the soil.

Feeding as it does in the stems, the pest cannot well be reached. Spraying with kerosene emulsion as a preventive measure is, however desirable, and especially in gardens where the insect was known to exist the previous season. All diseased portions of plants should be carefully burnt, and after

Celery Stem Fly—*continued.*

the crop has been lifted the quarters should receive a dressing of quicklime, which should be well incorporated. Dusting with soot has also proved beneficial.

CELMISIA (so called after Celmisius, who was said to be the son of the nymph Alciope, from whom the name of a nearly-related genus is derived). ORD. *Compositæ*. A genus embracing about twenty-five species of greenhouse or hardy, more or less silvery-silky, Aster-like, perennial herbs; one inhabits the Auckland and Campbell Islands, the rest are natives of New Zealand, one being also found in Australia. Flower-heads heterogamous, large, radiate; involucre broadly campanulate or hemispherical, the bracts many-seriate, imbricate; scapes (or scape-like peduncles) one-headed. Leaves all radical, rosulate, simple, entire or toothed, frequently covered with appressed, white or buff tomentum. Four species have been introduced. For culture, *see* **Olearia.**

C. coriacea (leathery). *fl.-heads* 1½in. to 3in. in diameter; ray florets white, excessively numerous; disk yellow; scapes very stout, cobwebby and cottony. *l.* 10in. to 18in. long, ½in. to 2½in. broad, lanceolate, coriaceous, narrowed into broad, woolly sheaths, covered above with cottony hairs, below with dense white-silvery tomentum. New Zealand. Hardy. SYN. *Aster coriacea.*

C. Lindsayi (Lindsay's). *fl.-heads* 1in. to 2in. in diameter; ray florets thirty to forty, white, three-toothed at apex; disk yellow. *l.* 2in. to 4in. long, oblong-lanceolate, obtuse, very coriaceous, dark shining green above, white beneath. Stems densely tufted, 3in. to 6in. long. New Zealand, 1890. Hardy, but requires protection from damp. (B. M. 7134.)

C. Munroi (Munro's). *fl.-heads* 1in to 1½in. across; ray florets white; disk golden-yellow; scape longer than the leaves, stout. Stem short, crowned with a thick mass of erect and recurved, linear-lanceolate leaves 3in. to 5in. long and ¼in. to ⅜in. broad. New Zealand, 1896. Whole plant, except the upper surface of the leaves and florets, clothed with snow-white, appressed wool. Greenhouse. (B. M. 7496.)

C. spectabilis (remarkable). *fl.-heads* 2in. in diameter; ray florets white or pale lilac, very numerous, revolute; disk yellow, scapes several, stout, stiff, erect, longer than the leaves. May. *l.* numerous, strict, erect, usually 5in. to 7in. long, ½in. to 1in. broad, thickly coriaceous, ensiform, elliptic-lanceolate, or linear-oblong, narrowed at base, then dilating into broad, tumid sheaths 2in. to 4in. long. Rootstock woody. Mountains of New Zealand, 1882. Hardy. (B. M. 6653.)

CELOSIA. SYNS. *Lophoxera, Sukana.* About thirty species, natives of the warmer parts of Asia, Africa, and America, are comprised in this genus. To the information given on pp. 289-90, Vol. I., the following should be added. Giant Empress, brilliant purple combs; and Vesuvius, with golden yellow combs and the upper part bright red, are two showy varieties.

C. margaritacea (pearly-white). A synonym of *C. argentea.*

C. pyramidalis. Sir J. D. Hooker regards this as synonymous with *C. cristata.*

CELSIA. Including *Ianthe.* This genus embraces about thirty species, natives of South Europe, North Africa, Abyssinia, Western Asia, and India. To the species, &c., described on p. 290, Vol. I., the following variety should be added. *See also* **Alonsoa.**

C. Arcturus Linnæana (Linnæus'). *fl.* yellow, with a purplish throat. SYN. *C. sublunata* (B. R. 438).

C. sublunata (partly woolly). A synonym of *C. Arcturus Linnæana.*

CELTIDEÆ. A tribe of **Urticaceæ** (which *see*).

CELTIS. This genus embraces about fifty species, broadly distributed over tropical and temperate regions. To those described on p. 290, Vol. I., the following should be added:

C. orientalis (Eastern). A synonym of *C. Tournefortii.*

C. reticulata (netted). *l.* obliquely cordate-ovate, acuminate, acute, or obtuse, more or less oblique at base, very rough above, and very strongly reticulate-veined beneath. Texas, 1890.

CENARRHENES (from *kenos*, empty, and *arrhen*, a male; in reference to the stamen-like glands). ORD. *Proteaceæ.* A monotypic genus. The species, *C. nitida*, is a greenhouse shrub or tree, native of Tasmania. It has small flowers in axillary or terminal spikes, and alternate, toothed leaves 3in. to 6in. long. It has been introduced, but is not in general cultivation.

CENIA (from *kenos*, empty; in allusion to the bladder-like apex of the peduncle). SYN. *Lancisia.* ORD. *Compositæ.* A genus embracing about eight species of small, hairy, greenhouse or hardy annuals or perennials, natives of South Africa. *C. turbinata* (SYN. *C. pruinosa*) has been introduced, but it is not of much horticultural value (R. H. 1892, f. 36).

CENTAUREA. Star Thistle. Including *Cyanus* and *Plectocephalus.* Most of the species of this large genus are found in the Old World, only about three being American. Leaves radical or alternate, entire, or often toothed, cut, or once or twice-pinnatisect. To the species described on pp. 290-2, Vol. I., the following should be added:

C. Amberboï (Amberbo's). A synonym of *C. suaveolens.*

C. argentea (silvery). *fl.-heads* pale yellow; involucral scales pectinate-ciliated at apex. July. *l.* silvery-tomentose, petiolate, pinnatisect, Fern-like. Stems sub-erect. Crete, 1739. Half-hardy perennial, very effective when plunged in pots in bedding arrangements.

C. Clementei (Clemente's). *fl.-heads* yellow, of no beauty. Summer. *l.* all silvery-grey; radical ones pinnatipartite, with ovate-triangular, sub-aristate lobes; cauline ones few, sessile Stems erect, branched. *h.* 3ft. Spain, 1871. Hardy perennial.

C. gymnocarpa (naked-fruited). *fl.-heads* pink or purple. August. *l.* petiolate, elegantly cut, clothed with whitish, satin-like down. Stems branching, bushy, hard. *h.* 1½ft. South Europe, 1858. Half-hardy under-shrub.

C. Jacea (Jacea). *fl.-heads* purple or rarely white; involucre ovate-globose, the outer scales having a ciliated appendix. Summer. *l.*, radical ones somewhat toothed; cauline ones lanceolate, entire. Stems erect, branched. *h.* 1½ft. to 2ft. Central Europe. Hardy perennial.

C. Margarita (Margaret's). A synonym of *C. odorata alba.*

C. odorata alba (white) A variety with white, sweet-scented flower-heads and of dwarf habit. 1893. SYN. *C. Margarita.*

C. orientalis (Oriental). *fl.*-heads straw-yellow; involucre sub-globose, the scales pale or fuscous, long-pectinate-ciliated. Summer. *l.*, lower ones petiolate, pinnatipartite, the lobes linear-lanceolate and often pinnatifid; upper ones pinnatifid or lanceolate, obtusely mucronate. Stems erect, branched. *h.* 2ft. to 3ft. Siberia, 1759. Hardy perennial, very floriferous.

C. phrygia (Phrygian). *fl.*-heads reddish-violet, sub-globose, sessile amongst the uppermost leaves; involucral scales black, scariose. July and August. *l.* oblong, acuminate, scabrous, undivided, entire or mucronate-toothed; lower ones petiolate; uppermost ones sessile, almost eared. Stem erect, simple, pilose-scabrous. *h.* 2ft. Switzerland, 1633. Hardy perennial.

C. rutifolia (Rue-leaved). *fl.*-heads at first pale flesh-coloured, afterwards reddish; involucral scales ciliated, sulcate, spiny-mucronate. Summer. *l.* 6in. to 8in. long, snowy-tomentose, interruptedly bipinnatisect; uppermost ones spathulate. Bulgaria. Hardy perennial.

CENTAURIDUM. A synonym of **Xanthisma** (which *see*).

CENTIPEDES. These animals may be considered of benefit to gardeners. *See* **Myriapoda.**

CENTRADENIA. This genus embraces about five species, natives of Central America. To those described on p. 292, Vol. I., the following should be added:

C. floribunda (abundant-flowered). *fl.* of a lilac-rose colour, disposed in terminal panicles. *l.* ovate, entire, slightly oblique, reddish on the nerves beneath. Stems red. Guatemala. (F. d. S. 453.)

C. inæquilateralis (unequal-sided). The correct name of *C. rosea.*

C. ovata (ovate). *fl.* pink; petals obovate; cymes terminal, trichotomous, many-flowered. *l.*, three-nerved, petiolate, ovate, acute, glabrous, shining, pale beneath. Stems and branches erecto-patent. Central America, 1861.

CENTRANTHERA. Included under **Pleurothallis** (which *see*).

CENTRANTHUS. SYN. *Kentranthus.* About eight species, natives of the Mediterranean region, are comprised in this genus.

CENTRATHERUM (from *kentron*, a spur, and *ather*, an awn; the pappus consists of stiff awns). SYNS. *Ampherephis, Amphibesis, Crantzia, Spixia.* ORD. *Compositæ.* A small American genus (five or six species) of stove or greenhouse, diffuse, branched or rarely erect herbs, of which two have spread over the warmer parts

Centratherum—*continued.*

of the world. Flower-heads usually purple, on terminal or leaf-opposed peduncles. Leaves alternate, petiolate. *C. intermedium* (SYN. *Ampherephis intermedia*, S. B. F. G. 225) and *C. punctatum* (SYN. *Ampherephis aristata*) have been introduced, but are probably lost to cultivation.

CENTRIFUGAL. A term applied to an inflorescence of which the terminal flower blossoms earliest. Opposed to a Centripetal one, in which the lower or outer flowers are the first to expand.

CENTROCARPHA. Included under **Rudbeckia** (which *see*).

CENTROCLINIUM. Included under **Onoseris** (which *see*).

CENTROLEPIDEÆ. A natural order embracing about thirty species of very small herbs, nearly all Australian, and allied to the *Restiaceæ*; they are of botanical interest only.

CENTRONIA. SYN. *Calyptraria.* Flowers purple, large, disposed in large, terminal panicles; calyx furfuraceous or hairy; petals five to seven; stamens ten. Leaves ample, petiolate, entire or toothed.

CENTROPETALUM (from *kentron*, a spur, and *petalon*, a petal; in allusion to the spur-like appendage at the base of the labellum). Including *Nasonia.* ORD. *Orchideæ.* A small genus (five or six species) of dwarf, creeping, cool-house Orchids, natives of the Colombian Andes. Flowers mediocre, solitary in the upper axils; sepals sub-equal, spreading, free, or the lateral ones more or less connate; petals similar or broader; lip connate towards the base with the column, at length erect, the lateral lobes scarcely prominent or broader and embracing the column, the lamina spreading, ovate or broadly rounded, undivided. Leaves distichous, short. *C. punctatum* (described on p. 421, Vol. II., as *Nasonia punctata*) is the best-known species.

CENTROPOGON. This genus embraces upwards of eighty species of shrubs or under-shrubs, natives of the warmer parts of America and the West Indies. Flowers solitary, axillary, pedunculate, rarely disposed in a terminal, elongated raceme; calyx lobes leaf-like or reduced to mere teeth; corolla curved, the tube entire or with a short dorsal cut, the limb incurved, with nearly equal lobes. Leaves alternate, toothed or rarely dissected. To the species described on p. 293, Vol. I., the following should be added:

C. tovarensis (Tovar). *fl.* bright carmine, with a very long style, disposed in a terminal raceme. Winter. *l.* ovate-lanceolate. Stems somewhat woody. Venezuela.

CENTROSEMA (from *kentron*, a spur, and *sema*, a standard; the standard has a short spur behind). ORD. *Leguminosæ.* A genus embracing about twenty-six species of twining or prostrate, stove or greenhouse herbs or under-shrubs, mostly natives of Central or South America, and closely allied to *Clitoria.* Flowers white, violet, rose-coloured, or bluish, showy; standard broadly orbicular, with a short spur behind; wings falcate; keel broad, incurved, scarcely shorter than the wings; peduncles axillary, solitary or twin. Leaves pinnately three- to seven-foliolate, rarely one-foliolate or sub-digitately three- to five-foliolate. For culture of the few species introduced, *see* **Clitoria.**

C. brasilianum (Brazilian) The correct name of *Clitoria brasiliana.*

C. grandiflorum (large flowered). *fl.* of a beautiful lilac-rose, large and numerous. Brazil, about 1893.

C. virginianum (Virginian). *fl.* violet, 1in. long, pubescent outside; peduncles one- to four-flowered. July. *l.* trifoliolate; leaflets varying from oblong-ovate to linear, thin but firm, scabrous-pubescent. Stem very slender, twining. Florida, &c., 1732. Greenhouse. SYN. *Clitoria virginiana* (B. M. 1047).

CENTROSIS. A synonym of **Calanthe** (which *see*).

CENTROSTEMMA. Included under **Hoya** (which *see*).

CEODES. A synonym of **Pisonia** (which *see*).

CEPHAELIS. SYNS. *Callicocca, Carapichea, Cephaleis, Eurhòtia, Evea, Tapogomea.* As many as seventy species are included hereunder. *C. Bearii*, introduced in 1888, is a stove shrub, of no great beauty, with inconspicuous umbels of flowers.

CEPHALANDRA (from *kephale*, a head, and *aner, andros*, a male; the anthers are connate or coherent in a head). SYN. *Coccinia.* ORD. *Cucurbitaceæ.* A genus embracing twelve or fourteen species of stove or greenhouse, slender, prostrate, or climbing, glaucous or scabrid, usually tuberous-rooted herbs, natives of tropical Asia and tropical and South Africa. Flowers white or yellow, usually dicœcious; males solitary or sub-cymose at the apex of a slender peduncle; females solitary. Fruits cylindric or oblong, rather small, very fleshy. Leaves angled or lobed, sometimes glandular. Tendrils undivided. Two of the species have been introduced, but probably *C. quinqueloba* (B. M. 1820 and B. R. 82, under name of *Bryonia quinqueloba*) is no longer grown. For culture of the two species here described, *see* **Bryonia.**

C. indica (Indian). *fl.* whitish-yellow, 1in. long, all solitary; male peduncles 1in. long; females ¼in. long. *fr.* carmine-red, ovoid, 1in. to 2in. long. *l.* five-angular or occasionally five-lobed, 2in. to 4in. in diameter, papillose, scabrid; petioles 1in. long. Stem much-branched, angular, and grooved. India, Upper Guinea, &c., 1894. Stove. SYN. *Coccinia Moghadd.*

C. palmata (palmate). *fl.* yellow; male peduncles elongated, racemose; females shorter, racemose. April. *fr.* scarlet, marbled with white, as large as a pigeon's egg. *l.* palmately five-lobed, 3in. to 4in. long and broad; lobes ovate, acuminate; petioles 1½in. to 2in. long; rootstock very large. Natal, 1893. Greenhouse.

CEPHALANTHUS. This genus includes half-a-dozen species of erect shrubs or small trees, natives of Asia, America, and South Africa. Flowers yellow, in globose, compact, terminal and axillary heads, bractless. Leaves opposite and in whorls of three or four, shortly petiolate, oblong- or ovate-lanceolate; stipules short. To the species described on p. 293, Vol. I., the following should be added:

C. natalensis (Natal). *fl.* very numerous, in globose, terminal, peduncled heads 1in. to 1½in. in diameter; corolla-tube rose-red, the lobes green. Spring. *l.* about 1in. long, ovate, acuminate or obtuse, glabrous and shining above, pale beneath. South-east Africa, 1886. A small, much-branched, greenhouse shrub. (B. M. 7400.)

C. occidentalis angustifolius (narrow-leaved). A variety having lanceolate leaves, narrower than in the type. 1889. (R. H. 1889, p. 231, f. 71.)

C. o. brachypodus (short-footed). A variety having shortly-stalked leaves, usually in whorls of three.

CEPHALARIA. SYNS. *Lepicephalus, Succisa.* This genus includes about two dozen species, natives of Europe, Western Asia, North Africa, and Abyssinia. To those described on p. 294, Vol. I., the following should be added:

C. alpina (Alpine). *fl.-heads* pale yellow, terminal on the branchlets; involucral teeth eight, aristate, equalling the florets. June and July. *l.* pinnatisect, pubescent; segments lanceolate, decurrent, unequally serrated. Stems striated, somewhat velvety. *h.* 5ft. Alps and Greece. SYN. *Scabiosa alpina.*

CEPHALEIS. A synonym of **Cephaelis** (which *see*).

CEPHALINA. A synonym of **Sarcocephalus** (which *see*).

CEPHALOID. Head-shaped, or growing in a head.

CEPHALOMENES. *See* **Trichomanes.**

CEPHALOTAXUS. Chinese Yew. Four species are referred to this genus by Bentham and Hooker, three being Japanese and the other Chinese. To those described on p. 294, Vol. I., the following should be added:

C. Fortuni [not *Fortunei*] is a form of *C. drupacea.* The following are sub-varieties: *brevifolia* (short-leaved) and *longifolia* (long-leaved).

Cephalotaxus—*continued.*

C. Mannii (Mann's). *l.* linear, acuminate, 2in. long, ⅛in. to ¼in. broad, sub-falcate, shining above, paler beneath. *male heads* globose, on scaly peduncles; *female cones* three or four on a common peduncle, pedicillate. China, Khasia Mountains, &c. A small tree.

FIG. 225. CEPHALOTAXUS PEDUNCULATA FASTIGIATA.

C. pedunculata fastigiata. This distinct variety grows about 8ft. high, and is of bushy, pyramidal habit. See Fig. 225.

C. tardiva (late). A synonym of *Taxus baccata adpressa.*

C. umbraculifera (umbrella-bearing). A synonym of *Torreya grandis.*

CERADIA. Included under **Othonna** (which *see*).

CERAIA. A synonym of **Dendrobium** (which *see*).

CERAMBYCIDÆ. *See* **Beetles.**

CERASEIDOS. Included under **Prunus** (which *see*).

CERASTIUM. More than 100 widely-distributed species have been referred to this genus, but not more than forty are distinct as such. Flowers in terminal, dichotomous cymes; sepals five, rarely four; petals the same number, usually emarginate or bifid; stamens ten or more. Leaves variable, but rarely subulate. To the species described on pp. 294-5, Vol. I., the following should be added:

C. argenteum (silvery). A synonym of *C. tomentosum.*

C. decalvans (bald). A form of *C. tomentosum.*

C. tomentosum decalvans (bald). *fl.* white, numerous. May and June. *l.* covered with tufts of wool. Stems somewhat woody. Servia, 1892.

CERASUS. Including *Laurocerasus.* Bentham and Hooker include this genus under **Prunus** (which *see*). To the species described on pp. 295-7, Vol. I., the following should be added:

C. acida (acid). Montmorency Cherry. *fl.* white; umbels aggregate, sparse, sessile. April and May. *fr.* red or dark purple; juice colourless. *l.* flat, glabrous, shining, sub-coriaceous, elliptic, all acuminate; petioles glandless. Orient, &c.

C. a. pyramidalis (pyramidal). A garden variety, with erect branches, forming a pyramidal growth like that of the Lombardy Poplar.

C. Avium. In addition to the variety *mutiplex*, the following may be mentioned: *flore-pleno*, flowers double, pink in the centre, a fine variety; *pendula*, branches reflexed at the extremity; and *salicifolia* (SYN. *longifolia*), leaves elongated.

C. Capuli. Capollin or Capulinos of Mexico. *fl.* white, in terminal racemes similar to those of *C. Padus.* *fr.* red, pulpy, resembling small Cherries. *l.* oblong or elliptic-oblong, acute, finely toothed, glaucous-green beneath. Mexico, 1883. Shrub or small tree. (R. H. 1888, p. 137, f. 50, under name of *Prunus Capuli.*)

C. Chicasa. Chicasaw Plum. *fl.* white; umbels two- or three-flowered, the short pedicels and calyx glabrous. April. *fr.* red or yellowish-red, globose, ½in. or more in diameter, of a pleasant flavour. *l.* oblong-lanceolate or oblanceolate, acute, serrulated, nearly glabrous. Branches thorny. North America, 1806.

C. humilis (dwarf). A synonym of *Prunus Jacquemontii.*

C. japonica (Japanese). A synonym of *Prunus sinensis.*

C. Juliana pendula (drooping). A garden form, with pendulous branches. 1890.

C. Laurocerasus schipkaensis (Schipka Pass). An especially hardy form, from the Northern slopes of the Balkan Mountains. 1890.

C. Selzeri (Selzer's). A species of the *Padus* group, with yellowish-white fruit, and said to come true from seed. Carinthia and Styria, 1892.

C. serotina cartilaginea (cartilaginous). A garden variety having long, smooth, coriaceous leaves, resembling those of the Cherry Laurel. 1889.

C. s. pendula (pendulous). A weeping variety.

C. vulgaris (common). A synonym of *C. Caproniana.*

CERATOCAULOS. Included under **Datura** (which *see*), the correct name of *C. daturoides* being *Datura ceratocaula.*

CERATOCEPHALUS. Included under **Ranunculus** (which *see*).

CERATOCHILUS (of Blume). Included under **Saccolabium** (which *see*).

CERATOCHILUS (of Lindley). A synonym of **Stanhopea** (which *see*).

CERATOGYNUM. A synonym of **Sauropus** (which *see*).

CERATOLOBUS. Two or three species are included in this genus. Flowers polygamo-monœcious, usually twin, the lower ones sessile and hermaphrodite, the upper ones stipitate, male or neuter, bracteate; spadix 4in. to 6in. long, loosely paniculate; spathe solitary, pod-like, complete, linear-oblong, ancipitous. Fruit globose or ellipsoid, one-celled, one-seeded. Leaves alternate, equally pinnatisect; rachis prickly. **C. Findlayanus** is in the Kew Collection, but is not in general cultivation. *See also* **Korthalsia.**

C. Micholitziana (Micholitz'). A synonym of **Bacularia Micholitziana** (which *see*).

CERATONEON EXTENSUM. *See* **Tilia—Insects.**

CERATOPHYLLEÆ. A very small natural order (one or two species) of widely-dispersed, aquatic herbs, ranking between *Empetraceæ* and *Gnetaceæ*; they are of botanical interest only.

CERATOPTERIS. Eaton, in his excellent work on North American Ferns, says *C. thalictroides* "is an annual, growing from the spore, forming its prothallus with the antheridia and archegonia producing its embryo, and growing first into a plantlet with minute, obovate fronds, and soon into a mature plant, buoyed up by the spongy leaf-stalks of its fronds, and later on sending up into the air fully-developed sterile and fertile fronds, and at last dying and contributing its proportion of decaying vegetable matter to its native lagoons." In a cultivated state the spores must be preserved; they require to be sown early in the spring, in some very moist loam, where they will germinate and grow freely. When sufficiently strong, the seedlings should be plunged into the water so that the little crowns are quite covered. The plant may also be increased by pegging on to the surface of moist soil the numerous bulbils with which its barren fronds are quite covered, and which soon produce a crop of young plants of rapid growth. It succeeds best when the pot containing it is plunged to the rim in water of a uniform temperature of from 60deg. to 65deg.

CERATOSANTHES (from *keras, keratos*, a horn, and *anthos*, a flower; in allusion to the shape of the blossoms). ORD. *Cucurbitaceæ*. A small genus (two or three species) of slender, climbing, stove herbs, with large, tuberous roots, natives of the warmer parts of America and the West Indies. Flowers racemose. Leaves palmately lobed. *C. tuberosa* (B. M. 2703) has been introduced, but is probably no longer in cultivation.

CERATOSPERMUM (of Persoon). A synonym of **Eurotia** (which *see*).

CERATOSTEMA. The plant described on p. 80, Vol. II., as **Gonocalyx pulcher** is probably a species of this genus.

CERATOSTIGMA (from *keras, keratos*, a horn, and *stigma*, a stigma; alluding to the stigmas being beset with short, horn-like excrescences). SYN. *Valoradia*. ORD. *Plumbagineæ*. A small genus (three or four species) of greenhouse or hardy, perennial herbs or shrubs; one is Chinese, another Himalayan, and one or two are Abyssinian. Flowers densely capitate-spicate at the tips of the branches; calyx tubular, glandless, deeply five-cleft, the lobes narrow; corolla salver-shaped, the tube long and slender, the limb of five obtuse or retuse, spreading lobes. Leaves alternate, obovate or lanceolate, more or less setose-ciliated. Only one species calls for mention here. It thrives in ordinary garden soil, and may be increased by divisions.

C. plumbaginoides (Plumbago-like). The correct name of the plant described on p. 169, Vol. III., as *Plumbago Larpentæ* (F. d. S. 307). SYN. *Valoradia plumbaginoides* (B. M. 4487).

CERATOTHECA (from *keras, keratos*, a horn, and *theke*, a case, a capsule; in allusion to the horned fruit). SYN. *Sporledera*. ORD. *Pedalineæ*. A small genus (two species) of erect, pubescent, stove or greenhouse (? always) annual herbs, natives of tropical and South Africa. Flowers solitary in the axils, shortly pedicellate: calyx five-parted or deeply five-cleft; corolla tube enlarged above, the limb sub-bilabiate, with spreading lobes; stamens four, didynamous. Leaves opposite, or the upper ones alternate, ovate, toothed. *C. triloba*, the only species in cultivation, is probably a biennial. Seeds should be raised in heat, and the plants, when strong enough, removed to the greenhouse. Rich loam, a sunny position, and plenty of water when growing, are essentials to success.

C. triloba (three-lobed). *fl.* in opposite pairs, shortly pedicellate, with a minute, imperfect flower at the base of each; calyx erect; corolla pale violet-purple, with darker streaks, 3in. long, pilose. September. *l.* polymorphous, the lower ones long-petiolate, varying from broadly ovate-cordate to broadly triangular and three-lobed, crenate, the broadest leaves 8in. across; floral ones narrowly ovate, shorter than the flowers. Stem 5ft. high. Natal, 1886. (B. M. 6974; G. C. 1887, ii., p. 492.)

CERATOZAMIA. SYN. *Dipsacozamia*. The half-dozen species comprised in this genus are only found in Mexico.

CERBERA. *Tanghinia* (described on p. 8, Vol. IV.) is included hereunder by Bentham and Hooker. The genus includes about four species, natives of Madagascar, tropical Asia, and the Pacific Islands; several others formerly classed under *Cerbera* being now referred to **Kopsia, Ochrosia, Tabernæmontana,** and **Thevetia.**

C. Tanghin (the native name). The correct name of *Tanghinia venenifera*.

CERCIDIPHYLLUM (derivation not explained). ORD. *Magnoliaceæ*. A monotypic genus. The species, *C. japonicum*, is a tree or shrub, which proves hardy on walls in our more Southern districts. It thrives in any fairly good soil, and may be increased by seeds or by layers. At present it is rare in cultivation.

CERCIS. To the species described on p. 298, Vol. I., the following should be added:

C. occidentalis (Western). *fr.*, pods oblong, very obtuse, shortly apiculate at apex, scarcely stipitate. *l.* almost reniform, very obtuse. *h.* 15ft. Texas. Shrub.

CERCOCARPUS. Five species, natives of California and Mexico, are referred to this genus. Flowers sessile, shortly pedicellate, solitary or fascicled, axillary or terminal; calyx tube persistent, pedicel-like, the limb deciduous, five-lobed; petals wanting; stamens fifteen to twenty-five. Leaves alternate, petiolate, simple, entire or serrated, straight-nerved. To the species described on p. 298, Vol. I., the following should be added:

C. betulifolius (Birch-leaved). A synonym of *C. parvifolius glaber*.

C. parvifolius (small-leaved). *fl.* solitary or in pairs, on short pedicels, recurved. June. *fr.* having a very long, densely plumose tail. *l.* scarcely 1in. long, cuneiform-obovate, silky-pubescent or at length nearly glabrous above, tomentose-canescent beneath, toothed towards the apex. Rocky Mountains, 1881. A low, half-hardy shrub.

C. p. glaber (glabrous). *fl.* two to six in a fascicle. April *l.* about 2in. long, nearly glabrous above. California, 1885. About twice as large as the type. SYN. *C. betulifolius*.

CERCOSPORA. A genus of very destructive fungi, several species of which are common in Europe and in America. The genus is chiefly characterised by olive-coloured, worm-like septate conidia. All the more important species have been briefly described and treated under the various plants affected. For instance, *C. circumscissa* is dealt with under **Peach Fungi,** Vol. III.; it is, however, not entirely confined to the Peach, being found upon the Apricot, Cherry, Nectarine, and the Almond. In those countries, too, where the last-named is extensively grown, the trees suffer considerably owing to their premature defoliation. Allusion has already been made to the pale spots which form upon the foliage. After a time, however, the diseased portions frequently collapse, leaving holes, which has gained for the disease the common name of Shot-Hole Fungus.

Another very common species in America is *C. apii*, which causes the Leaf-Spot or Leaf-Blight of Celery. In this disease the leaves are first noticed to bear small, greenish-yellow spots, which gradually increase in size and change to brown. Eventually the leaves assume a most unhealthy look, and fall.

C. Bloxami is found in this country upon Turnips and other *Cruciferæ*. *C. beticola* is responsible for the Leaf Spot of Beet so common in the United States; *C. lilacis* for a disease of Lilac (*Syringa*); and *C. angulata* for the Leaf-Spot of Currant.

From very careful experiments in the case of the species affecting Celery and the Peach, the best way of controlling the disease is to spray early in the season with a solution of Ammoniacal Carbonate of Copper (*see* **Fungicides**); while for the Beet a weak solution of Bordeaux Mixture may be tried in early summer as in the other cases. All infected leaves, fruits, and shoots should be burned.

CEREUS. About 200 species of this genus are known, natives of tropical and sub-tropical America, the West Indies, and the Galapagos Islands. (*See also* **Echinopsis** and **Pilocereus,** which are included under *Cereus* by the authors of the "Genera Plantarum.")

For cultural purposes this large genus may be divided into Night-Flowering, Semi-Scandent, and Globose or Columnar-stemmed species.

NIGHT-FLOWERING SPECIES. The most interesting group is that of the climbing night-flowering kinds, on account of their singular habit of expanding their flowers in the dark, and of the very large size and brilliant colours of their flowers. In habit the plants of this set are trailers or climbers; their stems are either round or angled, and grow to a length of many feet, branching freely as they extend. By means of their roots, which are freely formed upon the stems, and which have the power of attaching themselves to stones or wood in the same way as Ivy does, these kinds soon spread over and cover a large space; they are, therefore, useful for training over the back walls in lean-to houses, or for growing against rafters or pillars—in fact, in any position exposed to bright sunlight and where there is a good circulation of air. Soil does not appear to play an important part with these plants, as they will grow anywhere where there is a little brick rubble, gravel, or cinders for their basal roots to nestle in. They have been grown in the greatest luxuriance, and have produced flowers in abundance with nothing more than their roots buried in the crumbling foundations of an old wall, upon which the stems were clinging. The chief consideration is drainage, as, unless the roots are kept clear of anything like stagnation, they soon perish through rot. During the summer the stems should be syringed morning and evening on all bright days, whilst in winter little or no water will be required.

Like all other Cactuses, these plants may be propagated by means of large branches, which, if placed in a porous soil, will strike root in a few weeks.

SEMI-SCANDENT SPECIES. These are characterised by a thin, drooping or trailing stem, and, though not strictly climbers, they may most fittingly be considered in a group by themselves. Some botanists have made a separate genus for them, viz., *Cleistocactus*, but for all practical purposes they may be grouped under the above heading, whilst popularly they are known as the Rat's-tail or Whipcord Cactuses. Two of them—viz., *C. flagelliformis* and *C. Mallisoni*—are generally grafted on the stem of some erect, slender Cereus or Pereskia; or they may be worked on to the stem of a climbing Cereus, such as *C. triangularis*, in such a way as to hang from the roof of a house. A large specimen of *C. flagelliformis*, growing from the climbing stem of *C. rostratus*, was, for a long time, conspicuous among the Cactuses at Kew, but, owing to the decay of the "stock" plant, this fine specimen no longer exists. A large Pereskia, trained along the roof in the Cactus-house at Kew, was grafted with a number of pieces of *C. flagelliformis*. In the same establishment a specimen of *C. Mallisoni* was grafted on the stem of another kind, and is very attractive when in flower. *C. serpentinus* thrives well upon its own roots. For the cultivation of this little group, the instructions given for the climbing and other kinds may be followed.

GLOBOSE AND COLUMNAR-STEMMED SPECIES. Many of these are unsuited for culture in ordinary plant-houses, whilst others are so rare that, although cultivated in botanical collections, they are not available for ordinary gardens, not being known in the trade. There are, however, a good many species that may be obtained from dealers in Cactuses, and to these we shall confine ourselves here. At Kew, the collection of Cereuses is large and diversified, some of the specimens being as tall as the house they are in will allow them to be, and the appearance they present is, to some eyes at least, a very attractive one. Such plants are: *C. candicans*, which is a cluster-stemmed kind, very thick and fleshy, and in shape like an Indian club; *C. chiliensis*, with tall hedgehog-skinned stems, the numerous ridges being thickly clothed with clusters of yellowish spines, which become dark-brown with age; *C. Dyckii*, 10ft. high, the stems thick and fleshy, with ridges 1½in. deep; *C. gemmatus*, a hexagonal, almost naked-stemmed species 10ft. high: *C. strictus*, *C. peruvianus*, *C. geometrizans*, and *C. Jamacaru*, which are tall, weird-looking plants, 10ft. or more high, some of them freely branched.

Cereus—*continued.*

To those described on pp. 299-300, Vol. I., the following should be added:

C. aggregatus (clustered). A synonym of *C. phœniceus.*

C. Berlandieri (Berlandier's).* *fl.* 4in. across, produced on the young, upright stems; petals bright purple, strap-shaped, in an irregular ring; stamens rose-coloured, clustered. Summer. Stems procumbent, not more than 6in. long and ⅜in. thick, bearing, along the ridges, little tubercles, crowned with short spines. South Texas and Mexico. Plant dwarf, creeping, very soft and watery. See Fig. 226.

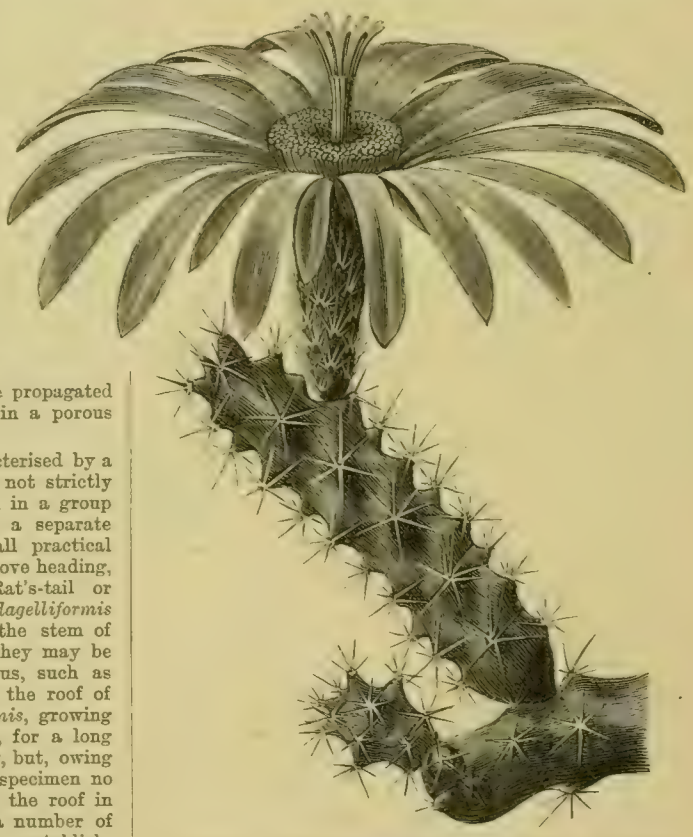

FIG. 226. PORTION OF PLANT, WITH FLOWER, OF CEREUS BERLANDIERI.

C. Blankii (Blank's). This only differs from *C. Berlandieri* in having deep rose flowers, flushed with crimson, and longer, broader, and less spreading petals. Summer. Mexico (at high elevations). See Fig. 227.

C. cærulescens (bluish). *fl.* about 8in. long, springing from the ridges; tube reddish-green; petals white, spreading, with toothed margins; stamens arranged in a sort of cup; anthers

Cereus—*continued.*

FIG. 227. PORTION OF STEM, WITH FLOWER, OF CEREUS BLANKII.

yellow. Summer. Stem erect, tall, bluish when young; ridges about eight, prominent, waved, bearing tufts of blackish wool, in which are set about a dozen black spines. Mexico, 1841. (B. M. 3922.)

C. cæspitosus (tufted). *fl.* deep rose-coloured; petals thirty to forty, oblong, acute, obtuse, or mucronate; tube having eighty to one hundred cushions clothed with long, ashy wool, and six to sixteen brown or blackish spines. Stems 4in. to 6in. high, 3in. to 4in. in diameter, simple or clustered, cylindric-ovoid, pale greyish or whitish, with scanty brown wool; ribs twelve to eighteen, ¼in. to ⅜in. broad at base; cushions close-set, with

FIG. 228. CEREUS CÆSPITOSUS.

twenty to thirty straight spines ¼in. or more in length. New Mexico and Texas, 1880. (B. M. 6669.) See Fig. 228.

C. Cavendishii (Cavendish's). A synonym of *C. Paxtonianus.*

C. Childsii (Child's). *fl.* pink, 30in. in circumference, composed of six rows of recurved petals, the numerous stamens standing well above them; opening at night. Probably a form of *C. variabilis.*

C. cirrhiferus (tendril-bearing). *fl.* bright red, nearly 4in. across, very regular, lasting about a week. Stems prostrate, branching, very proliferous, with roots along the main ones; branchlets upright, five-angled, with slightly-raised points or tubercles, upon which are ten short, hair-like spines, arranged in a star, and surrounding three or four erect central ones. Mexico, 1847. A small-growing kind.

Cereus—*continued.*

FIG. 229. CEREUS CTENOIDES.

C. ctenoides (comb-like).* *fl.* 3in. to 4in. across, produced in the ridges near the top of the stem; petals bright yellow, resembling a Convolvulus; stamens yellow; pistil white. June or July. Stem 3in. to 5in. high, about 3in. in diameter, egg-shaped, producing offsets at the base; ribs fifteen or sixteen, spiral, with closely-set cushions of whitish spines ¼in. long. Texas. Rare in cultivation. See Fig. 229.

FIG. 230. PORTION OF STEM, WITH FLOWER, OF CEREUS ENNEACANTHUS.

C. Engelmannii (Engelmann's). *fl.* purplish-carmine; sepals fifteen to twenty, ovate-lanceolate, prickly; petals acute; stigmas twelve, green, erect. *fr.* red, ovate. Stem ovate-cylindrical, eleven- to thirteen-ribbed, bearing the flowers laterally at the apex; prickles radiating, whitish, about thirteen in a tuft. California, 1885. (R. G. 1174 [1175a in text].)

Cereus—*continued.*

FIG. 231. FLOWER OF CEREUS GIGANTEUS.

C. enneacanthus (nine-spined). *fl.* freely developed on the ridges near the top of the stem; petals deep purple, spreading; tube spiny; pistil and stamens yellow. Stem seldom exceeding 6in. in height, less than 2in. in diameter, cylindrical, bright green, tufted in old specimens; ribs shallow, broad, irregular on the top, with spine cushions on the projecting parts; spines frequently twelve (although the specific name implies only nine) to a tuft. Texas. A rare plant in cultivation. See Fig. 230.

C. eruca (caterpillar-like). *fl.* yellow, 4in. to 6in. long. Stems prostrate, rarely branched, 1ft. to 3ft. long, 3in. to 5in. in diameter; ribs thirteen to twenty-one, with closely-set spine-tufts; spines stout, straight, the radial ones terete and nearly 1in. long, the central ones thicker, angled, or flattened, one wide, one in each tuft pointing downwards. California. A curious plant, creeping over any obstacle. "The manner of growth, with uplifted heads and prominent reflexed spines, gives the plant a resemblance to huge caterpillars."

FIG. 232. PORTION OF STEM, WITH FLOWER, OF CEREUS LEPTACANTHUS.

Cereus—*continued.*

C. extensus (long-stemmed). *fl.* about 9in. across, developed all along the stems, tube green, thick, 3in. long; larger scales yellow and green, tipped with red; petals white, tinted with rose. August. Stems long, rope-like, bluntly triangular, less than 1in. thick, with very short spines in pairs or threes about 1in. apart, and aërial roots. Trinidad, 1843. (B. M. 4066.)

C. Fendleri (Fendler's). *fl.* purple, sub-erect, 3in. in diameter; calyx tube and ovary bearing cushions covered with short spines; inner sepals twelve to fifteen; petals sixteen to twenty-four. June. Stem ovoid or sub-cylindric, 5in. to 7in. high, 3in. to 4in. in diameter, pale green, simple or rarely branched at base; ribs nine to twelve, ½in. deep; radial spines seven to ten, the central one 1½in. long. New Mexico, 1880. (B. M. 6533.)

C. giganteus (gigantic). *fl.* 4in. to 5in. long and wide, rarely produced in cultivation. Stems globose when young, afterwards becoming club-shaped or cylindrical, flowering when 10ft. to 12ft. high, but attaining four or five times that height. Mexico and California. The most gigantic of all Cacti, but a very slow grower, a cultivated plant, eight or ten years old, at Kew, being only 6in. high. See Fig. 231.

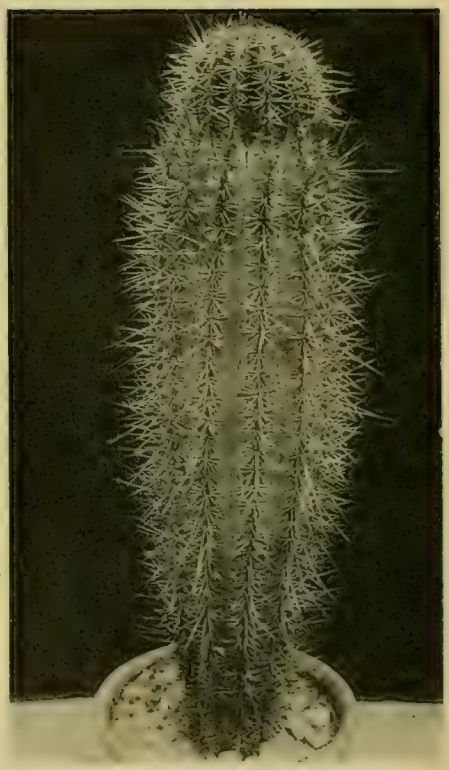

FIG. 233. CEREUS PECTEN-ABORIGINUM.

C. Hempelii (Hempel's). Stems dark green, ten-ribbed, furnished with brownish spines. Mexico, 1897. SYN. *Echinocereus Hempelii.*

C. hypogæus (underground). *fl.* 2in. long, the tube short, with a few spine-tufts; petals purplish, margined with yellow, oblong, mucronate. Aërial stems cylindric or clavate, seven- or eight-angled; tubercles with two to five or more bristle-like spines and three to five longer central ones. Underground stem minute, unarmed. Chili, 1832. (R. G. 1035.)

C. latifrons (broad-stemmed). A synonym of *Phyllocactus latifrons.*

C. Leeanus (Lee's).—*fl.* brick-red, four or five at the top of the stem; tube 2in. long, with yellowish, green-tipped scales; anthers yellow. Summer. Stems 1ft. high, 5in. in diameter at base,

Cereus—*continued.*

tapering gradually to the apex; ridges about twelve, ¼in. high, the angles sharp and clothed with clusters of pale brown spines, the central one 1in. long. Mexico, 1843. A desirable window-plant.

C. Lemairii (Lemaire's). *fl.* very fragrant; tube covered with green, crimson-edged scales; sepals not spreading star-like, tinged with crimson. June. Stem bluntly triangular; angles marked with a row of distant spines. Otherwise like *C. grandiflorus*. Antigua (?), 1854. (B. M. 4814.)

C. leptacanthus (slender-spined).* *fl.*, several to a branch; petals deep purplish-lilac in the upper half, the lower part white, forming a shallow cup, notched on the edges; stamens white; anthers and stigma orange. May and June. Mexico, 1860. Habit as in *C. Berlandieri*. See Fig. 232.

C. Mallisoni (Mallison's). *fl.* bright red, 4in. long and broad, with pale yellow stamens protruding 1in. beyond the throat, borne in abundance from the sides of the stems, lasting three or four days in beauty. Said to be a hybrid between *C. speciosissimus* and *C. flagelliformis*.

C. monstrosus (monstrous). A variety of *C. peruvianus*.

C. Napoleonis (Napoleon's). *fl.*, tube 6in. long, curved upwards, clothed with rose-tinted scales, widening into a whorl of greenish sepals; petals white, forming a shallow cup 8in. across; stamens yellow. Autumn. Stems triangular, light green, with clusters of short, stiff spines along the angles at intervals of 2in. Mexico (?), 1835. (B. M. 3458.)

C. Paxtonianus (Paxton's). *fl.* white, 3in. to 4in. across; calyx tube 2½in. long, unarmed; petals very many, in several series, incurved. September. Stem (of the Kew specimen) 4ft. high, about 1in. in diameter, erect, flexuous, branching towards the top, five- to six-angled, very lurid green, studded with spine-bearing pulvilli ¼in. apart. Brazil (?). (B. M. 7643.) SYN. *C. Cavendishii*.

C. paucispinus (few-spined). *fl.* axillary towards the top of the stem, 3in. broad; calyx sub-cylindric, with ten or fifteen clusters of short, pale spines; petals about thirty, dark red, tinged brown, elongate-spathulate, with concave tips. May. Stems 5in. to 9in.

FIG. 234. STEM, BRANCHES, BUDS, AND FLOWER OF CEREUS PROCUMBENS.

Cereus—*continued.*

high by 2in. to 4in. in diameter; ridges irregular in shape, ½in. to ¾in. in diameter; tubercles variable; spines three to seven, stout, pale red-brown. New Mexico, 1883. (B. M. 6774.)

C. Pecten-aboriginum (aboriginal comb). *fl.* white, 2in. to 3in. long. *fr.* globose, covered with yellow spines, forming balls 3in. in diameter. Trunk 1ft. in diameter. Ribs ten, purplish, clothed with closely-set tufts of hairs and about ten stout, straight spines 1in. long. *h.* 20ft. to 30ft. Sonora, 1894. See Fig. 233. The Indians use the bristly covering of the fruit as a hair-brush. (G. & F., 1894, p. 334, f. 54.)

C. pectinatus (comb-like). The correct name of *Echinocactus pectiniferus*. SYN. *C. pectiniferus*.

C. p. rigidissimus (very rigid). *fl.* bright rose-red, the lower part of the petals white. Stems 1ft. high, with reddish spines.

C. p. robustus (robust). *fl.* bright rosy, with the lower part of the segments white. *h.* 1ft. Mexico, 1890. A robust variety, growing 1ft. in height.

C. pectiniferus (tooth-bearing). A synonym of *C. pectinatus*.

C. pentalophus (five-winged). *fl.* 3in. across; petals rose-coloured, white in the centre; anthers yellow; stigma purplish-blue. Stem erect, about 1in. in diameter, ridges five, very prominent, wavy, sharp-edged, with little clusters of small spines about ½in. apart. Mexico, 1838.

C. peruvianus (Peruvian). *fl.* white within, reddish outside, solitary, 6in. long, scarcely expanded; sepals irregularly imbricated; stamens thirteen, rather long. July to October. Stem erect, six- to eight-angled; angles obtuse; prickles fuscous, short. *h.* 40ft. Tropical America, 1690.

C. p. monstrosus (monstrous). *fl.* much more expanded than in the type; outer sepals reddish, the inner ones pure white. Stem irregularly sulcate and tubercled; tubercles oblong, compressed, unequal, prickly at apex.

C. phœniceus (scarlet). *fl.* scarlet, less than 2in. long; stamens shorter than the petals; stigmas five. April to June. Stems ovate or sub-globose, 2in. to 3in. high, nine- to eleven-ribbed, obtuse, tufted, in its native haunts "forming dense masses, often 100 to 200 heads from a single base, the whole often of the shape and size of a bushel basket" (Engelmann); spines slender, almost bristly, the upper radial ones much shorter than the lower ones. North America. SYNS. *C. aggregatus*, *Echinocereus phœniceus*.

C. p. inermis (unarmed). A variety having no spines. 1896.

C. Phyllanthus (Phyllanthus). A synonym of *Phyllocactus Phyllanthus*.

C. Pitajaya (native name). A synonym of *C. variabilis*.

C. polyacanthus (many-spined).* *fl.* 2in. to 3in. long, lasting a week or more; tube spiny; petals deep blood-red, forming a shallow cup. Stem 10in. high, 2in. to 4in. in diameter, pale green or glaucous; ridges about eight, the spines placed along the angles in clusters of about half-a-dozen, ½in. apart. El Paso, Mexico. A beautiful species.

C. Pringlei (Pringle's). *fl.* white, tinged with green or purple, 2½in. to 3½in. long, not clustered at the summit, but scattered along the ribs for about 2ft. below the top. Stem erect, very stout, becoming 18ft. to 45ft. high and 2ft. to 4ft. in diameter, irregularly branching above the base; ribs thirteen, with contiguous areolæ, which become spineless on older portions; spines on younger areolæ terete, ½in. to ¾in. long, those on the older areolæ about fifteen, flattened, 1in. to 2½in. long. Lower California, &c., 1889. (G. & F. 1889, ii., p. 364, f. 92.)

C. procumbens (trailing).* *fl.* 3in. long and broad, developed on or near the ends of the branches; petals bright rose-purple, spreading and recurved; anthers forming a corona-like ring, enclosing the rayed stigma. May and June. Stems spreading, prostrate, emitting upright branches 3in. to 4in. high, ½in. thick, generally only quadrangular or square, with small spines in tufts along the angles. Mexico. A pretty little Cactus. See Fig. 234.

C. pterogonus (wing-angled). *fl.* pure white, sessile, 5in. to 6in. long and as much across, arising from just above the tuft of bristles at the margin; stamens pale yellow. August. Branches articulated; joints 3in. or more in thickness, 7in. long, usually four- (rarely five-) angled, the sinus of the lobes bearing a tuft of hair-like bristles and a spreading tuft of three or four prickles. Carthagena, South America, 1863. A straggling plant, needing support. (B. M. 5360.)

C. reductus (reduced). *fl.* three or four at the top of the stem, 3in. long and broad; petals white, slightly tinged with rose, serrated; stamens bright yellow, filling the whole flower-cup. Summer. Stem erect, 3ft. high, 4in. in diameter; ridges about fourteen, tumid and irregular, dingy glaucous-green; spines "as thick and strong as on a hedgehog," embedded in a tuft of grey wool, about a dozen in a cluster, most of them 1in. long, a few ½in. long. Mexico, 1796.

C. repandus. This old inhabitant of our gardens is now rare in cultivation; the flowers, which are very beautiful (see Fig. 235), unfortunately only last for a few hours. It requires a stove temperature.

C. Royeni (Royen's). A synonym of *Pilocereus Curtisii*.

Cereus—*continued.*

C. Sargentianus (Sargent's). *fl.* pink, with yellow anthers and a white style, 1in. long and wide, almost hidden by the spines. *fr.* red, smooth, said to be edible. Stems attaining a height of 15ft., five- or six-angled; spines ¼in. long, flexuous, disposed in dense tufts. Lower California, 1891. (G. & F. 1891, iv., p. 436, f. 69.)

FIG. 235. PORTION OF STEM WITH FLOWER OF CEREUS REPANDUS.

C. Tweediei (Tweedie's). *fl.* of a rich-orange-crimson, very handsome, numerous from the sides of the stem, 3in. long, curved upwards, the mouth oblique. September. Stem cylindrical, 3ft. to 6ft. high, with numerous furrows, the ridges not tubercled or mamillate; areolæ oval, brown-woolly; spines many, four or five stouter than the rest, erecto-patent. Buenos Ayres. (B. M. 4498.)

C. variabilis (variable). *fl.* whitish, 8in. long. Stems sub-erect, somewhat articulated and simple, or branched at base, green or glaucescent; ribs three to five, somewhat compressed, obtuse, obrepand; areolæ more or less remote, white- or fuscous-tomentose, at length woolly; prickles, six to eight outer ones, and one or two central ones, white, yellow, or blackish. Mexico, &c., 1809. SYN. *C. Pitajaya* (B. M. 4084).

CERINTHE. Although ten species have been described, the number distinct as such does not exceed four; they are natives of Europe, North Africa, and Western Asia. To the plants described on p. 300, Vol. I., the following should be added: it is probably a variety of *C. major*.

C. gymnandra (naked-anthered). *fl.* 1in. long; calyx leaflets having a purple band below the tip; corolla reddish-purple below, yellow above; anther-tips exserted. July. *l.* lin. to 4in. long, glaucous, ovate-oblong, contracted in the middle, bilobed at base, discoloured at tip, warty above; floral ones large. Stem 6in. to 12in. high. Italy, Algeria, &c., 1874. Annual. (B. M. 6130.)

CERISCUS (of Nees). A synonym of **Webera** (which *see*).

CEROPEGIA. SYN. *Systrephia.* The fifty species of this genus inhabit tropical and South Africa, the East Indies, the Malayan Archipelago, and tropical Australia. To those described on pp. 300-1, Vol. I., the following should be added:

C. bulbosa Lushii (Lush's). *l.* sub-sessile, very narrowly linear, 4in. to 8in. long (in the type they are petiolate, 1in. to 2in. long). Bombay, 1833. (B. M. 3300, under name of *C. Lushii.*)

C. Cumingiana (Cuming's). A synonym of *C. curviflora.*

C. curviflora (curved-flowered). *fl.* brown, often rather numerous, in a shortly-branched cyme; corolla tube 1in. long, densely hairy outside; corona having ten outer lobes and five inner ones. August. *l.* ovate or ovate-oblong, cordate at base, acuminate, 3in. to 4in. long; petioles ½in. to 1½in. long. Java, 1847. Stove. SYN. *C. Cumingiana* (B. M. 4349).

C. debilis (weak). *fl.* one to three on a peduncle, ½in. to ¾in. long; corolla pale purplish, glabrous, 1in. long, with some reflexed

Ceropegia—*continued.*

hairs inside. *l.* rather distant, ½in. to 1in. long, succulent, subterete. Stems several from a tuber, slender, weak, 3ft. to 4ft. long. Nyassaland, 1895. Stove.

C. Lushii (Lush's). A variety of *C. bulbosa.*

C. Meyeri (Meyer's). *fl.* pale purplish and blackish-green; corolla tube elongated pitcher-shaped, the segments linear, with reflexed margins. *l.* ovate-cordate, acuminate. South Africa, 1867. Plant pubescent. Greenhouse.

C. Monteiroæ (Mrs. Monteiro's). *fl.* about three at the top of short, lateral peduncles; sepals small, acute; corolla green, 2in. to 3in. long, the mouth trumpet-shaped, the five clawed lobes white, spotted purple-brown. July. *l.* opposite, 2in. to 3in. long, oblong-ovate, sub-acute or obtuse, succulent, pale green, the edges purplish, undulated. Branches white, mottled brown. Delagoa Bay, 1884. Greenhouse. (B. M. 6927.)

C. nobilis (noble). *fl.* pale purple on the outside, shortly pedicellate, about 1in. long, crenulated and ciliated. *l.* 1in. long, rounded. Stems very long. Root tuberous. South Africa, 1895. Greenhouse.

C. oculata (eyed). *fl.* very pale, spotted with purple below the lobes; corolla 2in. to 2½in. long, the base much inflated; coronal lobes short, two-toothed; peduncles hispid, 1½in. to 2in. long, four- to eight-flowered. September. *l.* ovate or ovate-cordate, acuminate, slightly ciliated, 4in. to 6in. long. Bombay, 1842. Stove. (B. M. 4093.)

C. sagittata (arrow-shaped). A synonym of *Microloma sagittatum.*

C. sinuata (sinuate). A synonym of *Microloma lineare.*

C. sororia (sisterly). *fl.* pale green, 1½in. to 2in. long, the reflexed lobes of the corolla darker green with a double row of transverse purple bars above, pink beneath; peduncles solitary, one-flowered. May. *l.* 4in. to 7in. long, less than ½in. broad, glaucous beneath. Stems almost filiform. Kaffraria, 1866. Greenhouse climber. (B. M. 5578.)

C. torulosa (somewhat twisted). A synonym of *Riocreuxia torulosa.*

C. Woodi (Wood's). *fl.* pinkish or violet, about 1in. long, with dark purple lobes; tube slender, distended at base. *l.* cordate-sub-orbicular, fleshy, variegated with silver markings on the upper surface; some of the axils producing small, globose tubers from which roots are emitted. Branches very slender, trailing. Natal, 1897. An excellent basket or rockery plant for a warm greenhouse. (G. C. 1897, xxii., pp. 357-8, f. 104.)

CEROPLASTES FLORIDENSIS. *See* **Scale.**

CEROPTERIS. *See* **Gmynogramme.**

CEROXYLON. SYNS. *Beethovenia, Klopstockia.* This genus embraces, according to the "Index Kewensis," nine species of very tall, unarmed, greenhouse Palms, found on the Andes of Colombia and Venezuela. Flowers rather large, monœcious on different spadices or polygamous; spadices elongated, much branched, the branches slender and flexuous; spathes about five, the lower ones complete, silky-tomentose; bracts minute. Fruit red or violet, as large as a Hazel-nut, globose or double. Leaves numerous, terminal, equally pinnatisect; pinnæ ensiform, acuminate, with obscure nerves.

C. ferrugineum (rusty). This species has been introduced to Continental gardens. (R. G. 1879, t. 977, f. 3.)

C. niveum (snowy). A synonym of *Diplothemium caudescens.*

CERVICINA. Included under **Wahlenbergia** (which *see*).

CESPEDESIA. Four species of tall, showy trees, natives of Peru, Colombia, and Panama, have been referred to this genus. Flowers yellow, showy, in large, terminal, bractless panicles; sepals and petals five, the latter much the larger and convolute. Leaves alternate, ample, coriaceous, obovate, narrowed to the petioles.

CESTRUM. Including *Meyenia* (of Schlechtendahl). Nearly 160 species of this genus have been described, but probably not more than 100 are distinct as such; they are restricted to the warmer regions of America. To those described on pp. 301-2, Vol. I., the following should be added:

C. Endlicheri (Endlicher's). The correct name of *C. corymbosum.*

C. Hartwegi (Hartweg's). *fl.* in cymose fascicles; corolla scarlet and glabrous within, wholly pubescent outside, nearly 1in. long; peduncles purplish. *l.*, those on the stem 4½in. long (including the petioles) and 2in. broad, pale beneath; those on the branches similar, but smaller. Branches terete, pubescent-tomentose. Bogota, 1883. Stove shrub.

CETERACH. An old genus of Ferns, now divided between **Asplenium** and **Gymnogramme** (which *see*). *A. officinarum* is identical with *Asplenium Ceterach.*

CETONIA AURATA. *See* **Rose Beetle.**

CEYLON BORAGE. *See* **Trichodesma zeylanicum.**

CHABRÆA. Included under **Leuceria** (which *see*).

CHADARA. A synonym of **Grewia** (which *see*).

CHÆNACTIS (from *chaino*, to gape, and *aktis*, a ray; the enlarging orifice and limb of the marginal corollas in most species simulates a kind of ray). ORD. *Compositæ.* A genus embracing about a dozen species of mostly hardy annual or perennial herbs or under-shrubs, natives of North (mostly Western) America. Flower-heads yellowish, white, or flesh-coloured, pedunculate, solitary or cymose; involucre campanulate or sub-hemispherical; receptacle flat, foveolate; pappus usually shorter or of fewer paleæ in the outer florets. Leaves alternate, mostly pinnately dissected. *C. tenuifolia*, the only species known in cultivation, thrives in ordinary garden soil, and may be increased by seeds or by division.

C. tenuifolia (slender-leaved). *fl.-heads* yellow, ¼in. high, scattered or paniculately disposed on short, slender peduncles. *l.* once or twice pinnately parted into irregular and small, linear or oblong, or sometimes nearly filiform, lobes. California (on the sea-shore), 1883. (R. G. 1275, f. 2.)

CHÆNANTHE. A synonym of **Diadenium** (which *see*).

CHÆNARRHINUM (sometimes erroneously spelt *Chænorrhinum*). Included under **Linaria** (which *see*).

CHÆNESTHES. A synonym of **Iochroma** (which *see*).

CHÆNOMELES. A synonym of **Cydonia** (which *see*).

CHÆNOSTOMA. SYN. *Sutera.* About twenty-six species, all South African, are referred to this genus. To those described on p. 302, Vol. I., the following should be added:

C. fastigiatum (pyramidal). *fl.* pink, small, in racemes 6in. to 9in. long. July to October. *l.* opposite, ovate-lanceolate, toothed. Stem much branched. *h.* 8in. to 12in. Annual. SYN. *Manulea fastigiata* (of gardens). There is a variety with white flowers.

CHÆROCAMPA ELPENOR. *See* **Sphingidæ.**

CHÆROPHYLLUM SATIVUM. A synonym of **Anthriscus cerefolium** (which *see*).

CHÆTANTHERA. Including *Proselia.* Twenty-six species, all natives of South America, are embraced in this genus.

CHÆTOCALYX. SYNS. *Bonninghausia, Rhadinocarpus.* There are about eight species of this genus; one is New Mexican, another is found in the Antilles, and the remainder are tropical South American. Flowers yellow; inflorescence axillary; pedicels one-flowered. Leaves impari-pinnate. Stipules lanceolate or linear.

CHÆTOCHILUS. A synonym of **Schwenkia** (which *see*).

CHÆTOCHLÆNA. Included under **Onoseris** (which *see*).

CHÆTOCLADUS. A synonym of **Ephedra** (which *see*).

CHÆTODISCUS. A synonym of **Eriocaulon** (which *see*).

CHÆTOSPORA. Included under **Schœnus** (which *see*).

CHÆTOTHYLAX (from *chaite*, a bristle, and *thylax*, a capsule). ORD. *Acanthaceæ.* A small genus (four or five species) of stove herbs, under-shrubs, or shrubs, dispersed over the region extending from South Brazil to Central America, and allied to *Justicia.* Flowers sessile, solitary or spicate; corolla limb bilabiate, the anterior lobe trifid; stamens two. Leaves entire. Only one species—*C. eustachiana* (SYN. *Justicia eustachiana*, B. M. 2076)—has been introduced, and probably that is lost to cultivation.

CHAILLETTIACEÆ. A natural order embracing about thirty-eight species of tropical trees and shrubs, ranking between *Meliaceæ* and *Olacineæ.* It is of no importance from a horticultural standpoint.

CHAIN FERN. *See* **Woodwardia.**

CHAIXIA. A synonym of *Ramondia.* *C. Myconi* is identical with **R. pyrenaica** (which *see*).

CHAKIATELLA. A synonyn of **Wulffia** (which *see*).

CHALCAS. A synonym of **Murraya** (which *see*).

CHAMÆBATIA FOLIOLOSA. A synonym of **Spiræa Millefolium** (which *see*).

CHAMÆBUXUS. Included under **Polygala** (which *see*).

CHAMÆCERASUS ALBERTI. A garden name for **Lonicera Alberti** (which *see*).

CHAMÆCERASUS ALPIGENA NANA. A garden name for **Lonicera alpigena nana** (which *see*).

CHAMÆCISTUS. *See* **Rhodothamnus Chamæcistus.**

CHAMÆCISTUS (of S. F. Gray). A synonym of **Loiseleuria** (which *see*).

CHAMÆCLADON (from *chamai*, dwarf, and *kladon*, a branch; in allusion to the habit of the species). ORD. *Aroideæ.* A genus comprising about twelve species of stove herbs, inhabiting tropical Asia and the Malayan Archipelago, and included by Sir J. D. Hooker ("Flora of British India") under **Homalomena** (which *see*). Flowers monœcious, all perfect; spathe small, sub-cylindrical, convolute below, gaping above, persistent; spadix inappendiculate, included, stipitate, sub-cylindrical, the male inflorescence much longer than the female. Leaves elliptic-ovate, varying to lanceolate, rarely cordate at base, the nerves nearly reaching the margins; petioles elongated, long-sheathing. Candex short or almost wanting. Only one species is known in gardens. For culture, *see* **Schismatoglottis.**

C. metallicum (metallic-lustred). *fl.*, spathe fuscous-purple, 1in. long, mucronate; peduncle purplish, slender, 1in. to 1½in. long. *l.* 3½in. to 5in. long, 2½in. to 3½in. broad, elliptic, sub-acute, shortly mucronate, rounded or slightly cordate at base, metallic-green above, purplish beneath; veins five to eight on either side the midrib, curved, ascending; petioles 2½in. to 3in. long, nearly ¼in. thick, channelled, purplish. *h.* about 7in. Borneo, 1884. (I. H. 1884, 539.)

CHAMÆCYPARIS. America and Japan are the headquarters of this genus, which is included by Bentham and Hooker under *Thuya*, and by Dr. Masters under *Cupressus.* To the species and varieties described on pp. 303-4, Vol. I., the following should be added:

C. filifera aurea (golden). This handsome form is distinguished from the type by the rich golden colour of the young growths. 1889.

C. Lawsoniana erecta alba (erect, white). A variety of slender, twiggy growth, stiff and compact, but feathery at the points, of a rich, glaucous-whitish-grey or silvery hue. 1882.

C. L. filifera (thread-bearing). Branches spreading, well clothed with deep green foliage; branchlets long and lightly divided. 1896. A very handsome form.

C. L. Rosenthalii (Rosenthal's). A garden variety, differing from the type in its pyramidal growth, and in the branchlets not drooping. 1886.

C. L. stricta (erect). An erect variety. 1888.

C. nutkaensis. Other varieties are: *albo-variegata* (white-variegated), *aurco-viridis* (golden and green), *gracilis* (slender), *lutea* (yellow), see Fig. 236 (for which we are indebted to Messrs. Veitch and Sons), and *nidifica* (nest-like).

C. obtusa. Other varieties are: *erecta viridis* (erect, green), *argentea* (silvery), *Ketcleeri*, *magnifica* (magnificent), *pygmæa* (dwarf), and *Troubetzkoviana.*

C. pisifera. There are numerous garden forms of this species, among the principal of which are *casuarinifolia* (having Casuarina-like leaves), *plumosa* (feathery), and *squarrosa* (squarrose).

C. sphæroidea atrovirens (dark green). *l.* and branchlets of a bright shining green.

Chamæcyparis—*continued.*

C. s. nana (dwarf). A very diminutive and quite glaucous variety.

C. squarrosa sulphurea (sulphur-coloured). This handsome variety differs from the type in the ends of its growths being of a pale sulphur-yellow. 1894.

Chamædorea—*continued.*

C. Ghiesbreghtii (Ghiesbreght's). A synonym of *Gaussia Ghiesbreghtii.*

C. graminifolia. This very graceful, plume-like species is shown in Fig. 237.

C. Hartwegii (Hartweg's). A synonym of *C. Sartorii.*

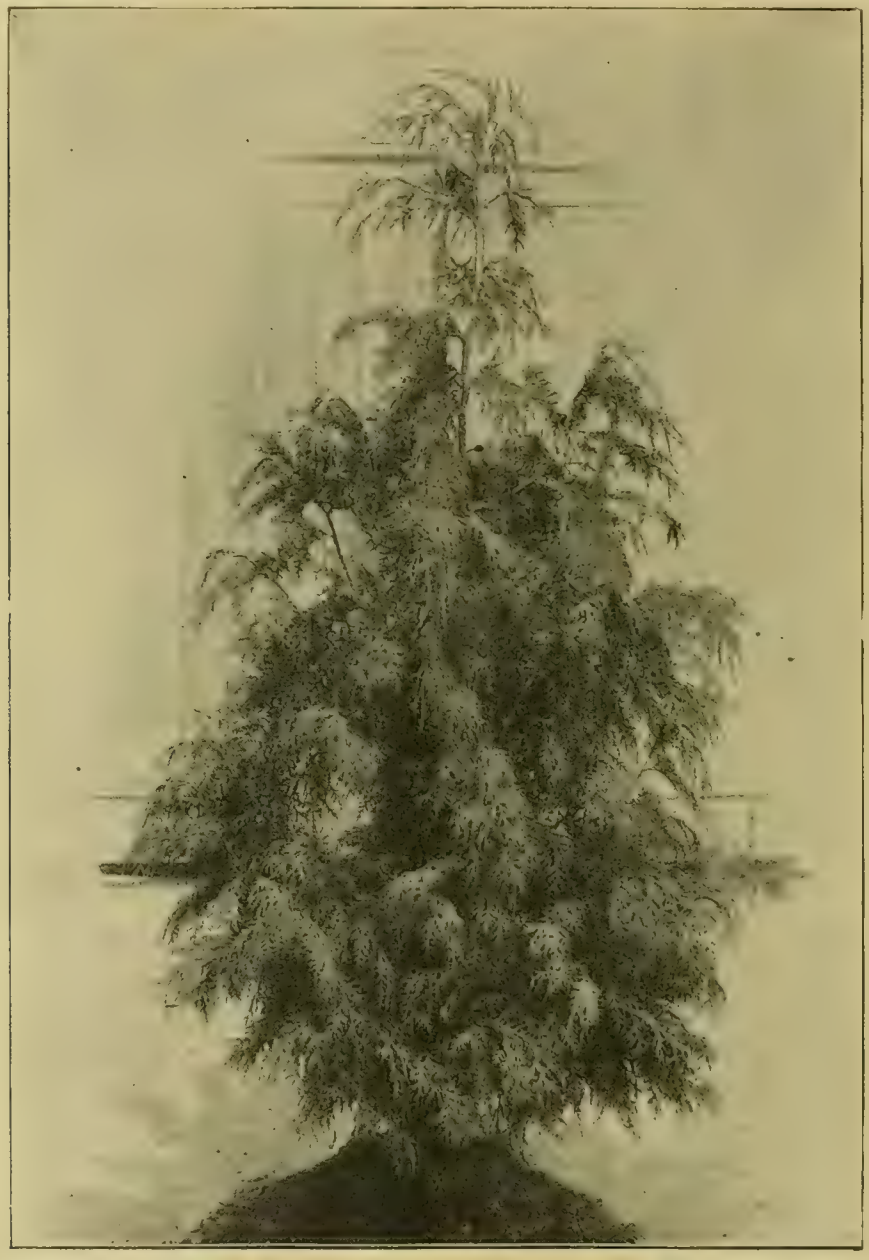

FIG. 236. CHAMÆCYPARIS NUTKAENSIS LUTEA.

CHAMÆDOREA. Including *Morenia.* This genus comprises about sixty species, natives of Western tropical America. To those described on p. 305, Vol. I., the following should be added:

C. concolor (one-coloured). *fl.*, spadix golden, much-branched. *fr.* golden, obovate. *l.* having oblong or trapezoid, falcate-acuminate pinnæ; petioles sub-terete, channelled at base. Stem annulate. Mexico.

C. Karwinskiana (Karwinski's). A synonym of *C. elatior.*

C. polita (polished). *l.* bifid when young, breaking up with age into two pairs of pinnæ, with a large, terminal leaflet; petioles (and stems) smooth. Mexico, 1884.

C. pulchella (rather pretty). *l.* produced in profusion, gracefully arched, pinnate, having very numerous linear leaflets. 1885. A very ornamental Palm, suitable for table decoration.

Chamædorea—*continued.*

FIG. 237 CHAMÆDOREA GRAMINIFOLIA.

C. stolonifera (stolon-bearing). *fl.* yellow, spadices intrafoliolar, branched, the males shorter than the leaves. *l.* terminal, 10in. long, bright green, shortly petiolate, obovate, cleft to below the middle into two dimidiate-oblong, nine-nerved segments; outer margin of the segments crenately toothed, the inner slightly convex; petioles 1in. to 1¼in. long. Stems slender, 3ft. high, growing in dense tufts, with interlaced stolons. South Mexico, 1882. (B. M. 7265.)

C. Wobstiana (Wobst's). An ornamental Palm, bearing a close resemblance to *C. Sartorii*, but it is more robust, and has more numerous leaves. 1885.

Other species in cultivation, but very rarely met with, are: *C. amazonica*, *C. corallina*, *C. elegantissima*, *C. Pringlei*, *C. pygmæa*, and *C. Ruizii*.

CHAMÆFISTULA. Included under **Cassia** (which *see*).

CHAMÆLAUCIUM. Ten species of this genus have been described, all Australian, but only one has been introduced.

C. plumosum (feathery). A synonym of *Verticordia Fontanesii*.

CHAMÆLIRIUM (from *chamai*, dwarf, and *Lirion*, a Lily; in allusion to the habit and affinity of the plant). SYNS. *Dasurus*, *Diclinotrys*, *Ophiostachys*. ORD. *Liliaceæ*. A monotypic genus. The species, *C. luteum* (SYNS. *Helonias lutea*, B. M. 1062, *H. pumila*), is a hardy, erect perennial, native of North America, with a dense raceme of tiny yellow flowers, leaves 3in. to 6in. long, and a stem 1ft. to 3ft. high. It is of no great horticultural value.

CHAMÆNERIUM, or **CHAMÆNERION.** Included under **Epilobium** (which *see*).

CHAMÆPEUCE. To the species described on p. 306, Vol. I., the following should be added:

C. afra (dark). *fl.-heads* bright purple, large; involucre thick, with lanceolate scales. *l.* dark green, blotched with white, disposed in a rosette, sessile, linear-lanceolate, glabrous above, white-tomentose beneath. Stem 2½ft. high, bearing eight to twelve flower-heads. Armenia, &c., 1894. A handsome, half-hardy, Thistle-like biennial.

C. Sprengeri (Sprenger's). *fl.-heads* white, fragrant; involucral scales smooth. *l.* linear-lanceolate, dark green, with white veins, the side veins running into two or three marginal spines. 1883. Garden hybrid. A hardy perennial, useful for rockwork and carpet-bedding.

CHAMÆPITHYS. Included under **Ajuga** (which *see*).

CHAMÆRANTHEMUM. Two or three species, all Brazilian, make up this genus. Flowers white or yellowish, solitary or in spikes; corolla tube long and slender, the limb of five spreading, imbricated, flat lobes; stamens four, didynamous, affixed towards the middle of the tube, included. Leaves rather large, membranous, entire, sometimes variegated. To the species, &c., described on p. 306, Vol. I., the following should be added:

C. Gaudichaudii (Gaudichaud's). *fl.* distant, disposed in a solitary, terminal spike 1½in. long. *l.* sub-cordate-ovate, acute, 3in. to 3½in. long, 2¼in. broad; petioles ½in. long. Stem creeping at base. 1869. Plant softly velvety. (F. d. S. 1767.)

C. igneum. *Stenandrium igneum* is identical with this species.

C. nitidum (shining). A synonym of *Ebermaiera nitida*.

CHAMÆRIPHES. A synonym of **Chamærops** (which *see*).

CHAMÆROPS. SYN. *Chamæriphes*. According to the "Genera Plantarum," the two species are restricted to the Mediterranean region, but the "Index Kewensis" includes one or two others, natives of South America and Mauritius. *See also* **Acanthorhiza, Livistona,** and **Nannorhops.**

C. humilis dactylocarpa (finger-fruited). This variety is distinguished from the type in having elongated fruit. 1889. There is also a tall, tree-like variety—*arborescens*.

C. h. elegans (elegant). A very beautiful variety for indoor decoration. See Fig. 238.

C. macrocarpa is a variety of *C. humilis*.

In addition to *dactylocarpa* and *macrocarpa*, the following varieties are grown at Kew: *bilaminata*, *elegans*, and *tomentosa*.

CHAMÆSTEPHANUM. Included under **Schkuhria** (which *see*).

CHAMÆTHRINAX (from *chamai*, dwarf, and *Thrinax*, an allied genus). ORD. *Palmæ*. A small genus of stove Palms. *C. Hookeriana*, a native of Buenos Ayres, is in the Kew collection, but is not in general cultivation.

FIG. 238. CHAMÆROPS HUMILIS ELEGANS.

CHAMELUM (from *chamelos*, low, humble; in allusion to the habit of the plant). ORD. *Irideæ*. A small genus (two species) of half-hardy, perennial herbs, natives of Chili. Flowers two or more in a spathe, very shortly pedicellate; perianth yellow, the tube slenderly funnel-shaped, the lobes sub-equal, erecto-patent; stamens affixed to the throat, the filaments connate in a cylindrical tube; spathes terminal, solitary or numerously aggregate. Leaves few, linear, rather broad, or sub-terete. *C. luteum* is known to cultivation. It thrives in well-drained, sandy loam, and may be propagated by division of the rootstock. In many parts of England it would probably prove hardy.

C. luteum (yellow). *fl.*, perianth 2in. long, highly glabrous, the limb segments lanceolate-linear; spathes two or three, erect, 1½in. long, glabrous, striated and pubescent at apex, sharply mucronate; scape terete, eight lines long, two-flowered. *l.* linear-filiform, erect, recurved, 2½in. long, scarcely half-a-line broad, shortly whitish-pubescent. 1884. (R. G. 1129, f. 6-9.)

CHAMOMILLA (in part). Included under **Alyssum** (which *see*).

CHAMORCHIS. Included under **Herminium** (which *see*).

CHARDOON. *See* **Cardoon.**

CHARITY. *See* **Polemonium cæruleum.**

CHARLES'S SCEPTRE. *See* **Pedicularis Sceptrum-Carolinum.**

CHARLWOODIA. Included under **Cordyline** (which *see*).

CHARTACEOUS. Resembling parchment or tough writing-paper in texture.

CHASMANTHIUM. A synonym of **Uniola** (which *see*).

CHASTE TREE. *See* **Vitex Agnus-castus.**

CHATELANIA. A synonym of **Tolpis** (which *see*).

CHAYOTA. A synonym of **Sechium** (which *see*).

CHEILANTHES. Lip Fern. Including *Allosorus* (in part), *Myriopteris*, *Plecosorus*, *Schizopteris*. Upwards of sixty species, many of them extending beyond the tropics, are embraced in this genus, in which there is no British representative. It is strikingly distinct, and includes some of the most elegant and beautiful Ferns in cultivation. They are all of an evergreen nature, and although coming principally from the Tropics the majority of them thrive best in a house where the temperature seldom exceeds 60deg. with artificial heat; a good many of them are even suited with a minimum greenhouse temperature of 45deg. in winter. This is no doubt owing to their being found in their native habitats at great elevations and in dry, rocky, exposed situations. Anyhow, wherever Cheilanthes are seen at a disadvantage and in bad condition, it is invariably due to their being kept in an over-heated, close stove, and frequently syringed—treatment which produces shapeless, emaciated plants deprived of all beauty. They should be grown as near to the light as possible, either on shelves against the glass, or in hanging baskets suspended from the roof, for which purpose some of them are very well adapted. No overhead watering or syringing should at any time be allowed, as this is quite as injurious to them as any extra heat; but they should be supplied with an abundance of water at the roots, and for this purpose they must be either potted or basketed in good fibrous peat and sand, with their crowns kept well above the rim of the pot. The compost should be very porous, and to that effect a small portion of sandstone and charcoal broken up into little pieces should be added to it. For the successful management of these charming Ferns, the two great evils to be avoided are strong, close heat and overhead moisture, and the points most beneficial to their welfare are abundance of water at the roots, an open, porous compost for them to grow in, a somewhat airy atmosphere, and plenty of light overhead. Most of the Cheilanthes, if not all, reproduce themselves freely and true from spores, which germinate very readily and form young plants in a comparatively short time.

To those described on pp. 307-9, Vol. I., the following should be added:

C. aurea (golden). *sti.* tufted, 2in. to 3in. long, ebeneous, slightly scaly. *fronds* 3in. long, deltoid, twice or thrice pinnatifid, yellow-mealy above, the under-surface covered with dense yellow powder; pinnæ deltoid, the lowest much the largest. *sori*, involucres broad and membranous. Peru and Guatemala. Stove. SYNS. *C. Borsigiana*, *Aleuritopteris aurea*.

C. Borsigiana (Borsig's). A synonym of *C. aurea*.

FIG. 239. CHEILANTHES FARINOSA.

C. californica (Californian). A synonym of *Hypolepis californica*.

C. candida (white). A synonym of *Nothochlæna sulphurea*.

C. chlorophylla (green-fronded). *rhiz.* stout, paleaceous. *sti.* contiguous, 1ft. to 1½ft. long, erect, polished, naked, dark chestnut-brown. *fronds* 1ft. to 1½ft. long, 4in. to 8in. broad, ovate-lanceolate, tripinnatifid; pinnæ 3in. to 5in. long, ¾in. to 1½in. broad, distant, lanceolate; pinnules lanceolate, cut down to the rachis into numerous entire, linear-oblong segments. *sori* numerous, small, roundish, placed on both edges. South America, 1833. Greenhouse. SYN. *Hypolepis spectabilis* (H. S. F. ii, 33 B).

FIG. 240. FROND OF CHEILANTHES HIRTA.

C. cuneata (wedge-shaped). *sti.* red, turning blackish with age. *fronds* glabrous, coriaceous, dull green, tri- or quadripinnate, cuneate or broadly-ovate, 1ft. to 1½ft. long (of which more than half is naked); pinnæ and pinnules ovate, acuminate. *sori* continuous all along the margins of the segments. Mexico. Greenhouse. SYN. *C. rufescens* (of gardens).

Cheilanthes—*continued.*

C. dicksonioides (Dicksonia-like). A synonym of *Hypolepis tenuifolia.*

C. Ellisiana (Ellis's). A form of *C. hirta.*

C. farinosa. This widely-distributed Fern has the under-surface of its fronds thickly coated with fine white powder. See Fig. 239.

C. ferruginea (rusty). A garden synonym of *Nothochlæna ferruginea.*

C. hirta Ellisiana (Ellis's). *fronds* broader, more finely divided, and more upright than in the typical plant, a frond of which is shown in Fig. 240.

C. profusa (profuse). A synonym of *Pellæa involuta.*

C. pulveracea (powdery). A synonym of *Nothochlæna sulphurea.*

FIG. 241. CHEILANTHES RADIATA.

C. radiata. This pretty little stove Fern was, owing to its general appearance (see Fig. 241), for a long time considered to be a species of *Adiantum.*

C. rufescens (reddish). A garden synonym of *C. cuneata.*

CHEILOPLECTON. Included under **Pellæa** (which *see*).

CHEILOSANDRA. A synonym of **Rhynchotechum** (which *see*).

CHEIMATOBIA BRUMATA. *See* **Winter Moth.**

CHEIRANTHERA (from *cheir*, the hand, and *anthera*, an anther; in allusion to the prominent anthers). ORD. *Pittosporeæ.* A small genus (four species) of greenhouse shrubs or under-shrubs, with flexuous or somewhat twining branches. Flowers nodding or sub-erect; sepals distinct; petals obovate-oblong, spreading nearly to the base; stamens bent to one side of the flower, facing the incurved aspect of the attenuated ovary; filaments filiform, much shorter than the long anthers; peduncles terminal, one- or loosely many-flowered. Leaves narrow, entire.

Cheiranthera—*continued.*

C. linearis and *C. parviflora*, which are probably the only species in cultivation, require similar treatment to **Sollya** which *see*).

C. linearis (linear). *fl.* azure-blue; pedicels erect; inflorescence terminal, corymbose. November. *l.* alternate, linear, slightly acute, entire or almost incised at apex. Australia, 1822. An erect shrub. (F. d. S. 856.)

C. parviflora (small-flowered). *fl.* purple, solitary, star-shaped, 1in. across, terminal, on long peduncles. July. *l.* sub-sessile, linear- or oblong-ovate or lanceolate, acute or obtuse, the margins recurved. Stems wiry. Western Australia, 1892. An elegant twiner, closely resembling the well-known *Sollya heterophylla.* (B. M. 7261.)

CHEIRANTHODENDRON. A synonym of **Cheirostemon** (which *see*).

CHEIRANTHUS. About a dozen very variable species, natives of temperate regions, are retained in this genus. Others formerly included hereunder are now referred to **Erysimum, Malcolmia, Matthiola,** &c.

CHEIROGLOSSA. *See* **Ophioglossum.**

CHEIROPTERA. *See* **Bats.**

CHEIROSTEMON. SYN. *Cheiranthodendron.* This genus belongs to ORD. *Sterculiaceæ.*

CHEIROSTYLIS. About eight species, natives of India, the Malayan Archipelago, and tropical Africa, are included in this genus. Sepals connate to the middle in a tube; lip with a saccate or cymbiform base and a two-lobed, toothed or pectinate limb; columnar appendages long, fleshy. To the information given on p. 310, Vol. I., the following should be added:

C. marmorata. The correct name, according to the "Index Kewensis," is *Dossinia marmorata.*

C. grandiflora and *C. montana* (B. H. 1861, t. 18) have also been introduced, but are not in general cultivation.

CHELONANTHERA. The species formerly classed under this name are now referred to **Cœlogyne** and **Pholidota.**

CHELONE. As now limited, this genus embraces only four species, several plants formerly included here being now classed under **Pentstemon.** *C. glabra* is regarded by Dr. Asa Gray as a distinct species.

CHENOLEA (from *chen*, a goose, and *leia*, prey; the plant is said to be eaten by geese). ORD. *Chenopodiaceæ.* A genus including about a score species of greenhouse or hardy herbs or shrubs, widely distributed. *C. diffusa* has been introduced, but is of no horticultural value.

CHENOPODIUM. *Blitum* is included in this genus.

CHERLERIA. Included under **Arenaria** (which *see*).

CHERMES ABIETIS. *See* **Spruce-Gall Aphis.**

CHERMES OF THE APPLE. This name is sometimes applied to the **Apple Sucker** (*Psylla mali*) (which *see*). It is, however, correctly given to a genus, one species of which, *C. abietis* (known as the Spruce Gall Aphis) is injurious to young Spruce trees.

CHEROKEE ROSE. *See* **Rosa sinica.**

CHERRY. Stocks are of more importance in the case of this fruit than many imagine. On some land the Wild Gean is best for all forms of trees, while on others the Mahaleb is preferable for either dwarf, wall, or half-standard trees. For all land with a very dry subsoil—sand or gravel—the Mahaleb is superior; while, for all except dwarf trees on deeper and heavier soil, the Wild Gean is the more suitable.

Cherry—*continued.*

Gumming is usually induced by either bad drainage or winter pruning. The remedy is obvious in either case.

Varieties. The following are all worth attention:

Autumn Bigarreau. *See* **Bigarreau Belle Agathe.**

Bigarreau Belle Agathe, or **Autumn Bigarreau.** Fruit small, black, and very sweet; valuable for the long time it will hang on the trees after ripening.

Bigarreau de Hedelfingen. Fruit large, fine deep black, and with a rich, high flavour. A fine mid-season variety.

Bigarreau de Schreken. Fruit large, black, of a rich and refreshing flavour. A good early variety, answering well as a bush or a wall tree.

Early Red. Fruit very large, red, juicy, and rich. An excellent early variety.

Emperor Francis. Fruit large, red, of fine flavour. A valuable late variety.

Geans.—GUIGNE D'ANNONAY. Fruit large, black, flesh firm, juicy, and rich flavour. An excellent early variety. GUIGNE'S DE WINKLER. Fruit large, red, of very luscious flavour, and will hang a long time on the trees. Late. DUKE'S BELLE DE CHOISY. Fruit large, pale yellowish-red, of sweet and pleasing flavour. Mid-season.

Monstrueuse de Mezel. Fruit very large, pale rose, sometimes striped with red. Flesh firm, very juicy, and of high quality. A good bearer on all forms of trees. Mid-season.

Noir de Guben. Fruit large and lustrous in colour, of good flavour. An abundant bearer.

CHERRY MOTH (*Argyresthia nitidella*). Belonging to that little-understood group of Moths known as the *Tineidæ* is the genus above named. The species is of some economic importance, inasmuch as it is at certain seasons responsible for a great deal of mischief to Cherry trees. The first indication that the gardener has that anything is amiss with his crop is the falling of the fruit in immense numbers, just after the "set." By many this is ascribed to night frosts, east winds, and the like; whereas in the majority of cases the injury is due to the attack of the minute caterpillar of the above-named abundant Moth (Fig. 242), its presence being detected by the minute hole to be found in the fallen fruits.

FIG. 242. CHERRY MOTH.

About midsummer the Moths are on the wing, and though observed in goodly numbers around Cherry trees, there is nothing in the insect's appearance to cause the gardener to view it with suspicion—clad in the simplest of attire, light brown, with whitish margins, and a dark brown band towards the centre. One characteristic of the genus is the peculiar resting position of these insects, which look as if they were trying to stand upon their heads, by reason of the position of the body. When egg-laying takes place, the Moths select the shoots of the tree for the purpose. The eggs remain unhatched through the winter, and are not affected by the severest cold.

As the spring approaches, and the embyrò fruit is forming, the caterpillars hatch out, and commence to work their way into the undeveloped fruits. They thus feed for about a fortnight, when the fruits fall to the ground in the manner indicated. The caterpillars are greenish, but afterwards take on a dull grey. They pupate in the fruits in a white cocoon.

By way of remedial measures nothing can be done, and the gardener is obliged to trust to the birds to preserve the balance. It will, however, be found good policy to collect the fallen fruits in spring and burn them.

CHEVALIERIA or **CHEVALLIERA.** Included under **Æchmea** (which *see*).

CHIAZOSPERMUM. Included under **Hypecoum** (which *see*).

CHICH PEA. *See* **Cicer arietinum.**

CHICKEN GRAPE. *See* **Vitis cordifolia.**

CHICKLING VETCH. *See* **Lathyrus sativus.**

CHICKWEED WINTERGREEN. *See* **Trientalis.**

CHILIAN CROCUS. *See* **Tecophilæa cyanocrocea.**

CHILIANDRA. A synonym of **Rhynchotechum** (which *see*).

CHILIAN NUT. *See* **Guevina Avellana.**

CHILIANTHUS (from *chiloi*, a thousand, and *anthos*, a flower; the flowers are very numerous). ORD. *Loganiaceæ.* A small genus (four species) of greenhouse, tomentose, South African trees or shrubs, closely allied to *Buddleia*, but having exserted anthers; they bear dense cymes of small flowers disposed in a terminal panicle, and opposite, entire or toothed leaves. *C. oleaceus* has been introduced. For culture, *see* **Buddleia.**

C. arboreus (tree-like). A synonym of *C. oleaceus.*

C. oleaceus (olive-like). *fl.* white, very pretty; stamen much longer than the corolla; panicles corymbiform, densely many-flowered. September. *l.* opposite, shortly petiolate, oblong-lanceolate, entire, 1½in. to 3½in. long, white-tomentose beneath. Branches also tomentose, flexuous. *h.* 6ft. 1816. SYN. *C. arboreus.*

CHILIOPHYLLUM (of De Candolle). Included under **Zaluzania** (which *see*).

CHILOCALYX (of Turczaninow). A synonym of **Atalantia** (which *see*).

CHILODIA. Included under **Prostanthera** (which *see*).

CHILOGNATHA. *See* **Millipedes.**

CHILOSTIGMA. A synonym of *Aptosimum.* *See* **Ohlendorffia.**

CHIMAPHILA UMBELLATA. A synonym of **C. corymbosa** (which *see*).

CHIMONANTHUS. SYN. *Meratia.* This genus is monotypic.

CHINA ROSE. *See* **Rosa indica.**

CHINESE ARTICHOKE. *See* **Crosnes.**

CHINESE HAWTHORN. *See* **Photinia serrulata.**

CHINESE KIDNEY-BEAN. *See* **Wistaria chinensis.**

CHINESE LARCH. *See* **Pseudolarix.**

CHINESE PARASOL. *See* **Sterculia platanifolia.**

CHINESE PEPPER. *See* **Xanthoxylum piperitum.**

CHINESE PRIMROSE. *See* **Primula sinensis.**

CHINESE SACRED LILY. *See* **Narcissus.**

CHINESE YEW. *See* **Cephalotaxus** and **Podocarpus chinensis.**

CHIOCOCCA. SYN. *Siphonandra.* Tropical America is the home of this genus, which embraces six to eight species.

CHIOGENES (from *chion*, snow, and *genos*, offspring; in allusion to the snow-white berries). Creeping Snowberry. SYNS. *Lasierpa, Phalerocarpus.* ORD. *Vacciniaceæ.* A monotypic genus. The species is a hardy, slender, trailing or creeping, marsh-loving evergreen, requiring similar culture to **Oxycoccus** (which *see*).

C. hispidula (slightly hispid). *fl.* white, very small and inconspicuous, solitary in the axils of the small, Thyme-like leaves, on short, nodding peduncles. April. *fr.* a white, globular berry, minutely bristly, slightly spicy, but otherwise insipid, ripe late in the summer. Branches filiform, strigose-hispid. North America, 1815. SYNS. *Gaultheria serpyllifolia, Phalerocarpus serpyllifolia.*

CHIONASPIS EUONYMI. *See* **Scale.**

CHIONASPIS FRAXINI. *See* **Ash Bark Scale.**

CHIONODOXA. The four species of this genus are natives of the Orient. To those described on p. 315, Vol. I., the following should be added:

C. gigantea (gigantic). A synonym of *C. Luciliæ grandiflora*

C. grandiflora (large-flowered). *fl.* violet-blue, white in the centre, larger than in *C. Luciliæ.* Plant also more robust. 1891. A garden variety.

C. Luciliæ. *See* **Chionscilla.**

C. L. grandiflora (large-flowered). *fl.* soft violet-blue with a small white centre, larger and more numerous than in the type, Asia Minor, 1873. SYN. *C. gigantea* (Gn., Sept. 3, 1892, t. 873).

Chionodoxa—*continued.*

C. sardensis (Sardis). *fl.* similarly coloured to those of *C. Luciliæ*, but not shading lighter in the centre; perianth stellate-infundibuliform, the limb twice exceeding the tube; pedicels cernuous; scape two- to six-flowered. *l.* convolute-channelled. 1887. (Gn. xxviii., p. 178; R. G. 1255 B-C.)

CHIONOPHILA (from *chion*, snow, and *phileo*, to love; the plant is found growing on the snow-capped Rocky Mountains of Colorado). ORD. *Scrophularineæ*. A monotypic genus. This species is a dwarf, hardy perennial, glabrous or nearly so, thriving in well-drained soil on the rockery. It may be propagated by seeds or by division.

C. Jamesii (Dr. James's). *fl.* few or many in a dense spike, mostly secund; corolla dull cream-colour, above ¼in. long. Summer. *l.* thickish, entire, mostly radical in a tuft, spathulate or lanceolate, tapering into a scarious, sheathing base; those on the scape-like flowering stems one or two pairs or occasionally alternate, linear. *h.* 1in. to 3in. 1888. (G. & F. 1888, i., p. 79, f. 15.)

CHIONSCILLA (name compounded from *Chionodoxa* and *Scilla*). ORD. *Liliaceæ*. This name is applied to a series of natural hybrids between *Scilla bifolia* and *Chionodoxa Luciliæ*. For culture, see **Scilla**.

C. Alleni (Allen's) is a very handsome plant, in colour and general habit resembling a good *C. Luciliæ*, but the perianth segments are cut to the base; in structure the plant comes near to *Scilla bifolia*. 1889. (G. C. 1897, i., p. 191, f. 57.)

CHIRITA. SYN. *Calosacme*. Including *Liebigia* and *Tromsdorffia* (of R. Brown). This genus embraces about twenty species, mostly Indian, a few being West Malayan and Chinese; it is very closely allied to *Didymocarpus*, but the stigma is "said to be sub-entire in *Didymocarpus*, bifid in *Chirita*; in *Chirita* it varies with age" (C. B. Clarke). To the species described on pp. 315-6, Vol. I., the following should be added:

C. depressa (depressed). *fl.* violet, 1¼in. long; corolla tube somewhat inflated, thrice as long as the rounded lobes; cymes few-flowered, shortly pedunculate. June. *l.* rosulate, shortly and broadly petiolate, broadly ovate, obtuse, bluntly serrated. Rhizome short, stout. China, 1889. Greenhouse. A dwarf species, soon forming a dense mass of foliage. (B. M. 7213.)

C. hamosa (hooked). *fl.*, corolla ⅜in. long, the tube slender, nearly white, the mouth pale blue or somewhat rose-coloured; peduncles connate and adnate to the petiole. *l.* opposite, ovate or elliptic, acute, 1in. to 6in. long, ½in. to 4in. broad, rounded at base, weakly hairy on both surfaces. Stem varying from ½in. to 20in. in length. India, 1896. SYN. *Rottlera hamosa* (R. H. 1896, p. 184).

C. Horsfieldii (Horsfield's). *fl.* drooping; corolla pale yellowish-white, with a purple tinge near the base, tubular, the limb of five spreading lobes; peduncles aggregated. February. *l.* large, opposite, spreading, ovate or elliptical, acuminate, serrated, hairy above, rough with harsh down. Stem herbaceous, 1½ft. to 2ft. high. Java, 1847. SYNS. *Liebigia speciosa* (B. M. 4315), *Tromsdorffia speciosa*.

C. Walkeri (Walker's). *fl.*, larger peduncles one- to five-flowered. Otherwise like *C. Moonii*. Ceylon, 1845. (B. M. 4327, under name of *C. Walkeriæ*.)

CHIRONIA. Fourteen species of this genus have been described. To those given on p. 316, Vol. I., the following should be added. Several plants formerly included here are now referred to **Exacum, Orphium, and Sabbatia.**

C. angustifolia (narrow-leaved). A synonym of *Orphium frutescens*.

C. decussata (decussate). A synonym of *Orphium frutescens*.

C. frutescens (shrubby). A synonym of *Orphium frutescens*.

C. palustris (marsh-loving). *fl.* rose-red, numerous, in branching, leafy cymes; calyx ¼in. long; corolla nearly 2in. across, the segments obtuse. Summer. *l.*, radical ones densely tufted, 4in. to 5in. long, very narrow-spathulate, obtuse; cauline ones sessile, connate by their bases. Stem stout, 1ft. to 1½ft. high. (B. M. 7101.)

C. pedunculatis (long-pedunculate). *fl.* reddish-purple, 1¼in. across, borne on long pedicels; corolla tube terete, equalling the ovate, acuminate lobes. July to October. *l.* sessile, cordate or rounded at base, ovate-lanceolate, acute or acuminate, three-nerved. 1835 and 1887. Plant decumbent. (B. M. 7047; B. R. 1803.) SYN. *C. trinervis*, of gardens (P. M. B. iii. 149).

C. trinervis (three-nerved). An old garden name for *C. pedunculatis*.

CHLÆNACEÆ. A small natural order (eight species) of trees and shrubs, of botanical interest, confined to Madagascar, and ranking between *Dipterocarpeæ* and *Malvaceæ*.

CHLAMYDOSTYLIS. A synonym of **Nemastylis** (which *see*).

CHLAMYSPORUM. A synonym of **Thysanotus** (which *see*).

CHLIDANTHUS. SYN. *Coleophyllum*. This is a monotypic genus, the species being that described on p. 316, Vol. I.

CHLOIDIA. A synonym of **Corymbis** (which *see*).

CHLOÖPSIS. A synonym of **Ophiopogon** (which *see*).

CHLORITA VIRIDULA. *See* **Potato Insect Pests.**

CHLOROCODON (from *chloros*, green, and *kodon*, a bell; in allusion to the colour and shape of the flowers). Mundi-root. ORD. *Asclepiadeæ*. A monotypic genus. The species is a tall, leafy, warm-greenhouse climber, allied to *Periploca*. It thrives in any good soil, and is increased by cuttings of the ripened shoots, inserted in sand, under a bell-glass, in bottom-heat. The aromatic roots are extensively collected and sold by the native tribes, being used as a stomachic.

C. Whitei (A. S. White's). *fl.* pale green, between rotate and campanulate, ⅜in. across, the segments purple towards the base internally, where there is a thickened ring swelling into five notched lobes; cymes axillary, corymbose, many-flowered. August. *l.* opposite, shortly petiolate, 6in. to 10in. long, broadly oval-oblong, abruptly acuminate, cordate at base. Natal, 1869. (B. M. 5898; G. C. 1895, ii., p. 224; R. H. 1895, p. 375.)

CHLOROPHORA (from *chloros*, greenish, and *phoreo*, to bear; alluding to the economic properties of *C. tinctoria*). ORD. *Urticaceæ*. A genus comprising only two species of milky, stove trees; one is a native of tropical America, and the other is tropical African. Flowers dicœcious, the males in cylindrical spikes, the females in globose or oblong heads; inflorescences of both sexes shortly pedunculate, solitary in the axils. Leaves alternate, petiolate, entire or toothed, penniveined; stipules lateral, caducous. The following species thrives in almost any soil, and is readily propagated by cuttings of the half-ripened wood.

C. tinctoria (dyers'). Fustic-tree. *fl.*, male inflorescence 1¼in. to 2¾in. long; females ¼in. to ½in. in diameter; peduncles pubescent or puberulous. *l.* distichous, 2in. to 6in. long, 1¾in. to 2¾in. broad, ovate or ovate-elliptic, entire or toothed, rarely lobed; petioles ¼in. to ½in. long. *h.* 20ft. Tropical America, 1739. Yellow, brown, olive, and green dyes are extracted from the wood. SYN. *Maclura tinctoria*.

CHLOROPHYTUM. SYNS. *Asphodelopsis*, *Hartwegia* (of Nees), *Schidospermum*. The species are natives of Asia, tropical and South Africa, and America; they only differ from *Anthericum* in the capsule being acute-angled, and in the filaments being usually more or less dilated towards the middle. The following species call for description. For culture, *see* **Anthericum.**

C. arundinaceum (Reed-like). *fl.* white; perianth segments ¼in. to ⅓in. long; raceme 3in. to 8in. long, simple or shortly branched; scape stout, 6in. to 20in. long. *l.* oblanceolate, obtuse, acute, or acuminate, 6in. to 18in. long, 1¼in. to 2in. broad, usually narrowed into a broad petiole. Eastern Himalayas, 1876. Half-hardy.

C. brachystachyum (short-spiked). *fl.* white, small, in a dense raceme. *l.* Eucomis-like, 8in. long. Nyassaland, 1893. Stove.

C. elatum (tall). *fl.*, perianth whitish, ⅓in. long; racemes lax, ascending, 6in. to 12in. long; scape 3ft. to 4ft. long, including the inflorescence, which is copiously paniculate. *l.* twelve to twenty, lanceolate, firm, 1½ft. to 2ft. long, 1in. broad, with about thirty distinct ribs. South Africa. Greenhouse. (Ref. B. 216.)

C. e. variegatum (variegated). The correct name of *Anthericum variegatum*.

C. Kirkii (Kirk's). *fl.*, perianth white, greenish outside, ¼in. long; raceme lax, simple, 4in. to 5in. long; peduncle shorter than the leaves. Summer. *l.* about six to a stem, thin, lanceolate, 1½ft. long, ¼in. to 1in. broad. Mozambique, 1882. Stove.

C. rhizomatosum (rhizomatous). *fl.*, perianth ¼in. long, the segments white, with a brown keel; racemes two, lax, erect, 3in. to 4in. long; peduncle shorter than the leaves. August. *l.*, produced ones about six to a stem, firm, linear, acuminate, 6in. to 9in. long, ¼in. to ⅓in. broad, not petiolate. Rootstock vertical, ¼in. in diameter, bearing many surperposed relics of old leaves. Mozambique, 1885. Stove.

CHLOROSIS, or **BLANCHING**, is a disease found in many kinds of fruit-trees, as well as upon the Vine. As its second name suggests, it is characterised by a loss of colour in the foliage, which, instead of being green and healthy-looking, presents a yellowish, sickly appearance. In France the disease is very prevalent on Vines, especially

Chlorosis, or Blanching—*continued.*

those on soil containing lime. Though the leaves are most affected, the shoots in their vicinity also participate. The disease is to trees what anæmia is to the human subject. It is due to a lack of iron in the soil, and the remedy is therefore obvious, although it must be inferred that the disease sometimes entirely baffles the cultivator. Apricots, Peaches, and many other fruits are affected, as well as Cucumbers and their allies. So far as Vines are concerned, French growers have found it advantageous to change their stocks, using those which are found growing wild upon similar soils.

CHOCOLATE-NUT TREE. *See* **Theobroma Cacao.**

CHOCO-PLANT. *See* **Sechium edule.**

CHŒNOMELES, or CHÆNOMELES. A synonym of **Cydonia** (which *see*).

CHOIROMYCES ALBUS. *See* **Truffles.**

CHOISYA. *Juliana* is synonymous with this genus.

CHOKE-BERRY. *See* **Pyrus arbutifolia.**

CHOMELIA. Syn. *Anisomeris.* About a score species, natives of tropical America, are included in this genus.

CHOMELIA (of Linnæus). A synonym of **Webera** (which *see*).

CHONDRORHYNCHA. Colombia is the home of the few species included in this genus. Sepals sub-equal, narrow-oblong; petals much broader; lip articulated with the foot of the column, sessile, broad, erect, concave, undivided; pollen masses four. To the species described on p. 317, Vol. I., the following should be added:

C. bicolor (two-coloured). *fl.* white, with some purple markings on the middle and base of the lip; sepals 1in. long, the dorsal one ¼in. broad, the lateral ones ⅓in. broad; petals oblong, obtuse, ⅔in. long; lip nearly 1in. long, somewhat three-lobed; peduncles 2in. long, one-flowered. *l.* 1½ft. to 2ft. long, linear-lanceolate, acuminate. Costa Rica, 1894. Plant tufted.

C. fimbriata (fringed). The correct name of *Stenia fimbriata.*

C. Lendyana (Lendy's). *fl.*, sepals and petals whitish-yellow, the lateral sepals reverse and retrorse, the petals very large; lip darker than the sepals and petals, large, elliptic, with a central, bidentate callus. 1886.

CHONEMORPHA (from *chone*, a funnel, and *morpha*, a form; in allusion to the shape of the flowers). Ord. *Apocynaceæ.* A genus embracing about four species of tall-climbing, stove shrubs, natives of India and the Malayan Archipelago, and closely allied to *Trachelospermum.* Flowers white, rather large, in loose, branched cymes. Leaves opposite, ample. *C. macrophylla*, the only species introduced, thrives in a compost of sandy loam and peat, and may be increased by cuttings.

C. macrophylla (large-leaved). *fl.* sweet-scented; calyx ⅓in. long, tubular; corolla tube very short, hairy within, the throat 1½in. long, the limb 3in. broad. July. *l.* 10in. long and broad, opposite, orbicular to obovate, cuspidate, cuneate at base, pale and pubescent beneath. India, &c. 1884. (B. M. 7492.)

C. pubescens (downy). A synonym of *Holarrhena antidysenterica.*

CHORETIS. Included under **Hymenocallis** (which *see*).

CHORISIA (commemorative of J. L. Choris, an artist who accompanied Kotzebue round the world). Ord. *Malvaceæ.* A small genus (three species) of prickly, stove trees, found in tropical America. Flowers reddish, rather large; calyx cup-shaped, irregularly two- to five-lobed; staminal column five-toothed or five-cleft at apex; peduncles axillary or sub-racemose, with two or three bracteoles under the flowers. Leaves digitate; leaflets five to seven, entire or serrated. *C. speciosa*, the only species introduced, requires a rich, loamy soil. It may be propagated by seeds, sown in sandy soil, with bottom-heat.

C. speciosa (showy). *fl.* axillary, solitary, 3in. in diameter; calyx silky inside; petals yellowish, with dark brown rays on the densely pubescent back, oblong, spreading; stamens in a long tube surrounding the style. *l.* on long petioles; leaflets lanceolate, acute, serrated. Brazil, 1883. An ornamental tree.

CHORISTES. A synonym of **Deppea** (which *see*).

CHORIZEMA. About fifteen species, confined to Australia, are included in this genus. Flowers usually orange or red, in terminal racemes or rarely axillary; petals clawed; standard emarginate, rather longer than the oblong wings; keel much shorter than the wings. To the species, &c., described on p. 318, Vol. I., the following should be added:

C. cordatum. There is a variety *splendens.* 1883.

C. flavum (yellow). A synonym of *C. cordatum.* (G. M. B. i. 73.)

C. nervosum (nerved). *fl.* orange-crimson; standard about ¼in. long; racemes loose, few-flowered. Summer. *l.* broadly orbicular-cordate, pungent-pointed, much undulated, ¼in. long, often broader than long. *h.* 2ft. 1852. (L. J. F. 383.)

C. ovatum (ovate). A synonym of *C. rhombeum.* (B. R. 1523; P. M. B. iv. 153.)

C. rhombeum (of Loddiges). A synonym of *C. diversifolium.* (L. B. C. 1619.)

C. spartioides (Spartium-like). A synonym of *Isotropis striata.*

C. superbum (superb). A synonym of *C. cordatum.* (I. H. t. 29.)

CHOROZEMA. *See* **Chorizema.**

CHOTEKIA. A synonym of **Dysophylla** (which *see*).

CHRISTOPHER, HERB. *See* **Actæa spicata.**

Fig. 243. Chrysalidocarpus lutescens.

CHRYSALIDOCARPUS. Though somewhat rare in cultivation, *C. lutescens* is so elegant and decorative (see Fig. 243) that it should be included, if possible, in any select list of Palms.

CHRYSANTHEMUM. Including *Balsamita*, *Ismelia*, and *Leucanthemum.* Nearly 120 species have been referred to this genus, but not more than eighty are distinct as such; they are found in Europe, Asia (mostly temperate and North), America (mostly North), North and South Africa, and the Canary Islands. *C. Leucanthemum* (Ox-eye Daisy), *C. segetum* (Corn Marigold), and *C. Parthenium* (Feverfew Chrysanthemum) are well-known British representatives.

Not one of the Japanese sorts grown twenty years ago is met with now for exhibition or for any other purpose, and their names have practically disappeared

Chrysanthemum—*continued.*

from even Chrysanthemum specialists' catalogues. With the Incurved section, very few indeed of those most valued a quarter of a century ago are now considered worth cultivating. In the Anemone section there has likewise been the same advance; while the Early-flowering varieties, of which there is such a magnificent selection, were practically unknown. The same also applies to the Single and the Hirsute varieties, the single sorts in many instances being very pretty and most useful for cutting. In the Pompone and Reflexed sections there is the least advance, and it is a question if the last-named will ever become favourites. The thing to be regretted in connection with the exhibition Chrysanthemum is the tendency to coarseness in the flowers.

LATE-FLOWERING VARIETIES. Many growers plant out all their varieties with a view to increase or improve their stamina, and thus obtain better cuttings than those taken from pampered pot plants. A still better plan is to procure cuttings from a distance, where the conditions as regards soil and situation are totally different. Plants raised from these cuttings almost invariably produce far superior flowers to those obtained from home-grown ones.

When cuttings are received somewhat limp, they should be placed in lukewarm water for an hour; this will freshen them up and make them in good condition for potting. In November, or as early in December as the cuttings become large enough, take those growths that spring from the soil (not those on the stem, unless the stock is short), selecting those that are short, sturdy, and with good foliage. Carefully cut away the two lower leaves and insert the cuttings at once singly in small "sixties." These should be well drained and filled with a compost of leaf-mould and loam in equal proportions, with sufficient sand added to make the whole porous. Immediately after the cuttings are put in a thorough soaking should be given to settle the soil about them, and also to prevent the foliage from drooping. A low pit or frame, with a hot-water pipe round, is an excellent place to stand them, maintaining a temperature of 45deg., and keeping the place closed until the cuttings have rooted. If air is admitted by ventilation before the rooting process is completed, the foliage will be sure to flag. If the sun comes out brightly, lightly damp the foliage overhead with a syringe; this tends to keep the leaves plump.

The process of rooting varies considerably. Some varieties make roots very quickly, while others are very slow. Those that strike first should be removed to a cooler and more airy position, but safe from frost. The plants should be kept close to the glass to obtain all the light possible and induce a sturdy habit; unless this is done, particularly while the days are short, the plants become drawn and weakly. The plants should never suffer from lack of water from the time of their insertion as cuttings until after they have flowered. At the same time, continued saturation must be avoided.

By the end of March the cuttings will have filled their pots with roots, and should be potted into 5in. size, draining carefully, and covering the drainage with moss, to keep it free. At this potting the compost should consist of three parts good fibrous loam and one part well-decayed leaf-mould or spent horse-droppings, with a 5in. potful of fine bone-meal to every barrow-load of soil, thoroughly mixing the whole. If the loam is of a very heavy character, a little silver-sand may be added; but it is advisable not to make the soil too light. Press the soil moderately firm, and leave a space about ½in. deep at the top of the pot for water. If the plants are watered well a little time before potting, it will not be necessary to water them again for a day or so. When it is necessary, give a good soaking, using a fine rose on the pot in order to avoid displacement of the soil.

After potting, a cold frame, with the floor covered with coal-ashes, is the most suitable place for the plants, but still keeping them close to the glass, and also somewhat close for a few days, until the roots have started taking possession of the new soil. Afterwards air may be admitted freely on warm or sunny days; in fact, when the weather is very mild the lights may with advantage be taken right off. Any attempt at coddling will end in leggy plants, with no foliage at their base. Towards the end of April the lights may be left off the frames entirely, except in very cold weather, and by the middle of May the plants may be stood outside in an open, sunny position. By the end of May or early in June the plants may be transferred to their flowering pots. If required for exhibition, 8in. pots will be quite large enough; but if extra large plants are required

Chrysanthemum—*continued.*

for quantities of cut blossoms or conservatory decoration, 10in. or even larger-sized pots may be employed. The compost at this final potting should consist of three parts rich fibrous loam and one part dry horse-droppings, with a 7in. potful of bone-meal to each large barrow-load of soil; or failing bone-meal a similar quantity of Thomson's Manure may be used instead. The drainage of the pots ought to be carefully arranged (inverted oyster-shells are first-rate) and covered with moss, while a sprinkling of soot will keep out worms for a considerable period. The soil should be rammed moderately hard, and must not fill the pot. A space of 2in. or 3in. at the top should be allowed for a top-dressing later on.

From this time onwards, the plants will demand constant attention in watering, staking, and tying, and ample space should be provided for each plant. A very good position for them is by the side of a sunny walk, in a single line. By having stakes driven in at intervals, with stout string running from each other, the plants may be securely tied thereto, and thus prevented from being blown down or injured by strong winds, while the sun and light have full play upon both sides of the plants, ensuring thorough ripening of the wood. Some growers advise giving no liquid or other manures until the flower-buds have formed, but a little weak liquid manure, or a top-dressing of soot or soot-water, certainly improves the health and colour of the growth. Immediately the flower-buds are formed, a mulch of fibrous loam and decayed manure, in equal proportions, will prove highly beneficial, and from the time of the flower-bud formation until the flowers begin to expand frequent applications of diluted liquid manure, or some of the prepared chemical manures, will be very serviceable, bearing in mind that the roots can only take up or use a limited amount of plant-food, and any great excess above their requirements is likely to do more harm than good.

Stopping, bud-taking, &c., are comparatively simple matters, and depend a great deal upon the purpose for which the plants are grown. If for exhibition blossoms, it will be found advisable not to pinch or stop the shoots at all, but at each break to select from three to five of the strongest and best shoots, and rub out all the others. About the middle of August, or from then to early in September, these growths form buds (termed crown buds), and all except the centre or largest bud are pinched out. If these buds form in July or very early in August, they are too early for exhibition in November; consequently, they are taken out, and another shoot is made, which produces a "terminal," or second crown bud.

Between these crown and terminal buds there is a great difference; in many cases the colour is quite distinct on the same plant, as may be proved by allowing one shoot to produce a crown, and one a terminal bud. For this reason, some varieties are best from one, and some from the other. In describing the sorts for exhibition, it will be noticed that it is stated which is the best bud to choose. If possible, the buds should all be secured by the end of August. Very fine blossoms are obtained from buds formed early in September, but there is always a risk of their not being in time, and also a doubt as to their proving up to the exhibition standard. Immediately the buds are formed, it is advisable to lightly spray the plants with Bordeaux Mixture to prevent Mildew or other fungoid attacks.

At the end of September or early in October, the plants may be placed in a cool, light, airy house, where a little fire heat may be turned on to expel damp, especially in dull or foggy weather. Plenty of ventilation should be given whenever the weather is favourable, and any needless spilling of water about the house ought to be avoided, otherwise it will be apt to cause the flowers to "damp." While the blossoms are expanding it will be necessary to pull out a few of the petals, as some are almost sure to be awkward or out of place, and would, if allowed to remain, spoil the symmetry of a blossom.

When fully developed, an Incurved flower should be deep, full in the centre, towards which all the petals should incurve, and be also fresh and of good colour. The Japanese section should have all their flowers deep, wide, with good petals, and well coloured. The same applies in a lesser degree to the Reflexed; while the Anemone section ought to have the centre, or cushion, well developed, free from petals, and the outer florets or guard-petals in a well-formed circle round the cushion.

The dressing of flowers for exhibition is extensively practised by Chrysanthemum growers, and consists in the

Chrysanthemum—*continued.*

early removal of all malformed or useless petals. For instance, in an Incurved blossom some of the petals are ill-formed or twisted, and if allowed to remain would spoil an otherwise good flower; and the same applies to the Anemone section. Ivory tweezers and a fine small brush are employed to curl and fix the petals in a correct and symmetrical form. With a little practice on spare flowers it will not be found difficult to arrange the petals properly and thus improve the appearance of the flowers, although perhaps a little reducing them in size.

In arranging the blossoms on the exhibition-boards (Fig. 244), the finest or largest flowers should be at the back, the colours so arranged as to give the best effect, and the blossoms raised sufficiently to show their depth and true character. Good taste, neatness, and punctuality in staging, are quite as requisite to the man who would become a successful exhibitor as fine flowers.

For the supply of cut flowers, or for plants intended only for decorative purposes, the details of culture are a little different from those which obtain when dealing with plants for exhibition. To furnish flowers in November, the cuttings should be "struck" or rooted as advised in November; but for flowers at Christmas and the New Year, January is soon

Chrysanthemum—*continued.*

frame, in the compost already described. Immediately it is observed that the cuttings have rooted, ventilation should be given gradually, and the plants kept strong and short-jointed, pinching out all side-shoots as they appear, and only permitting one stem to grow. When the cutting-pot is well filled with roots, a shift into a 5in. or 6in. pot should be given; in this the plant should flower. By confining the growth to one stem, a short, strong plant, about 1ft. high, and with one large, well-coloured flower at the top, will be the result. These little plants are very useful for room-decoration, as they fit very well into vases, and continue fresh for a week or longer. More than one flower-bud will form, but all except the largest and best buds should be removed.

By sowing seed there is always a chance of raising new varieties equal to, and sometimes distinct from, existing varieties. Most of the leading seedsmen now advertise seed for sale. The best time to sow is in January or February, placing it in gentle heat to germinate, and afterwards keeping the seedlings close to the glass. Potting should be done as often as necessary, until finally the plants are in 7in. or 8in. pots, in which they should flower. It is always advisable to pot all the seedlings, however weak and

FIG. 244. EXHIBITION CHRYSANTHEMUM BLOSSOMS ARRANGED ON A BOARD.

enough to put in cuttings, growing them on sturdily as previously suggested, and also potting them similarly; but, instead of waiting for the plants to branch out naturally, it is advisable to pinch out points of the shoots several times to obtain dwarf and bushy specimens. All stopping or pinching of the shoots should, however, cease by the end of July. Proper attention to staking must be paid; and when the plants form their flower-buds in September, it is wise to cut away all the buds except three or four on each shoot. If all the buds were left, the lower ones on each shoot would fail to open except in the case of the Pompones; with these all the buds should be retained. It will be found that this early removal of useless buds greatly improves the quality of the flowers, making them more valuable for home use or for market.

The remarks already made on feeding, mulching, and spraying with a fungicide are applicable to bush-plants; in fact, to grow any Chrysanthemum thoroughly well, freedom from insect or fungoid pests and generous treatment are absolutely essential. In pinching or taking out the tops of the Japanese varieties in April or May, it is well to cut the shoots back 2in. or 3in. These points make splendid cuttings, and will root readily if placed in a cool close

delicate they may appear, as there is often the very best amongst the weakest, and to throw such away as worthless might be the means of discarding the only good variety in the whole batch. On the other hand, equally as satisfactory varieties occasionally originate from strong and moderately strong-growing varieties, showing the uncertainty of pinning faith to either strong or weak ones as the most likely to produce anything specially noteworthy. As a rule, the blossoms the first year are very disappointing, the major portion of the flowers coming single and semi-double, and a novice would probably throw them all away; this is a mistake to be avoided, for out of a large quantity raised from seed we have never found a really good flower the first year. The better plan is to carefully select those combining good colour and width of flower with the largest number of petals or florets, and from such take cuttings in November, growing them on in the usual manner. If any of them are of merit, they will show their true character in the second year, and the grower can decide if they are worth retaining.

To the species and varieties described on pp. 318-24, Vol. I., the following should be added. Except where otherwise stated, the species are hardy perennials. *See also* **Pyrethrum.**

Chrysanthemum—*continued.*

C. arcticum (Arctic). *fl.-heads* white, tinged with lilac or rose; ray florets nearly 1in. long; pappus none; involucral bracts brown-margined. Summer. *l.* cuneate, with a long-tapering base or petiole, crenately toothed or incised at the summit; uppermost ones small, nearly entire. *h.* 9in. to 12in. Arctic Alaska, Japan, &c., 1801. A useful plant for the rockery. (R. G. 785.)

FIG. 245. FLOWER OF CHRYSANTHEMUM EDITH TABOR.

C. Broussonetii (Broussonet's). *fl.-heads* 3in. across; ray florets pale lilac, tinged with yellow at base; disk dark purple, changing to golden-yellow; peduncles elongated. May. *l.* distant, ovate or obovate, pinnatifid; segments lanceolate, often again pinnatifid and toothed. *h.* 2ft. to 3ft. Canary Islands, 1858. SYN. *Ismelia Broussonetii* (B. M. 5067).

C. cinerariæfolium (Cineraria-leaved). *fl.-heads* 1½in. in diameter; involucral bracts rounded and whitish at apex; ray florets white, tridentate; disk yellow. July and August. *l.* pinnatisect; segments narrow-elongated, few-lobed, pinnatifid or pinnatisect, spreading. Stem erect, slender, one-headed. Dalmatia. (B. M. 6781.)

C. grandiflorum (large-flowered). *fl.-heads* yellow, 1in. across. *l.* serrated; radical ones obovate; cauline ones lanceolate, sessile, inciso-serrated. Stems simple, one-headed, hairy. Algeria, 1884. Biennial. SYN. *Balsamita grandiflora.*

C. hæmatomma (red-eyed). *fl.-heads* rose-coloured, 3½in. to 4in. across, borne in great profusion in its native country; but the plant is described as "of too straggling a habit for it to become a favourite pot plant." Madeira, 1888. Half-hardy.

C. indicum (Indian). The plant from which the numerous garden varieties have sprung, and which is now only seen in those forms. It is closely allied to *C. sinense.* SYNS. *C. japonicum, C. tripartitum.*

C. inodorum (scentless). A synonym of *Matricaria inodora.*

C. japonicum (Japanese). A synonym of *C. indicum.*

C. lacustre (lake-loving).* *fl.-heads* white, numerous. Autumn. *l.* broader and more fleshy than in *C. maximum* (with which this species has been confused), not so much narrowed at base, and more regularly toothed. Portugal. (G. C. 1889, v., p. 589, f. 100.)

C. maximum (greatest). *fl.-heads* white, solitary; involucral scales oblong, whitish; whitish-margined at apex; ray florets about 2in. long. *l.*, lower ones petiolate, cuneate at base, lanceolate, toothed from the middle to the apex; cauline ones sessile, broadly linear-lanceolate, serrated. Stem ascending, erect, simple or somewhat branched towards the base. *h.* sometimes 10ft. Pyrenees. (G. C. n. s., xxvi., p. 273.)

C. multicaule (many-stemmed). *fl.-heads* golden-yellow, solitary at the ends of the stems or branches, 1½in. to 2½in. in diameter;

Chrysanthemum—*continued.*

ray florets twelve to twenty, broadly oblong, obscurely crenate at the tip. July and August. *l.* succulent, very variable, linear-spathulate, trisected or pinnatifid. Stems many, terete, simple or branched, 6in. to 12in. high. Algeria, 1887. A glaucous, hardy annual. (B. M. 6930.)

C. nipponicum (Nippon). *fl.* resembling Marguerites, 2½in. to 3½in. across, having numerous white rays and a yellow disk. *l.* coriaceous, dark green, oblong-spathulate, 3½in. long, the margins irregularly denticulate. China, 1895. This species is distinguished from its herbaceous congeners in having shrubby stems, attaining 1½ft. in height. It has been described as "a dwarf, compact, shrubby Ox-eye Daisy."

C. serotinum (late). *See* **Pyrethrum uliginosum.**

C. tripartitum (three-parted). A synonym of *C. indicum.*

C. Zawadskii (Zawadski's). *fl.-heads* rose-tinted, numerous; involucral scales ciliated. *l.* pinnatifid. Stems sub-shrubby, corymbose, pubescent above. Galicia, &c. Habit tufted.

Japanese. From careful observations made, it seems that about ten years is the life of an exhibition variety in the Japanese class. In fact, it must be a very good variety indeed to stand as long as that on the show table. With all other classes it is more difficult to raise new varieties of such merit as will entitle them to a place on the exhibition stands; consequently, they retain their hold upon the public for a much longer period. The following are splendid varieties for exhibition:

ANNIE PREVOST, pure white, with incurving florets; the plant has a strong dwarf habit, height 3ft.; AUSTRALIE, soft amaranth, florets broad and long, a grand exhibition variety, crown bud; BEAUTY OF ADELAIDE, mauve-pink, florets long and deep, crown bud; BEAUTY OF THRUMPTON, rich rosy-purple, with reflexed florets, flowers of large size and good form, height 4½ft.; BELLUM, clear pink, florets incurving, very handsome, terminal bud; BOULE D'OR, beautiful straw colour, florets

FIG. 246. FLOWERS OF CHRYSANTHEMUM GOLDEN SHOWER.

broad, deep, and incurved, crown bud; CHARLES DAVIS, bronzy-buff shade, a grand flower, with long, straight florets, crown bud; C. B. HAYWOOD, white, long, stiff florets, immense flower, crown or terminal buds; C. HARMAN PAYNE, dark purple, florets

Chrysanthemum—*continued.*

FIG. 247. FLOWER OF CHRYSANTHEMUM MR. A. G. HUBBUCK.

long and somewhat coarse, enormous flower from a crown bud; C. W. RICHARDSON, lovely yellow, florets long and beautifully curled, terminal bud; DAKOTA, deep yellow, the florets being mixed up together in a most attractive form, height 5ft.; DUKE OF WELLINGTON, salmon-buff, florets long and very broad, splendid terminal bud; EDITH DASHWOOD, delicate pink or rose, with very long florets, which are gracefully twisted, a very pretty, large variety, height 5ft.; EDITH TABOR (Fig. 245), lemon-yellow, florets long, broad, and deep, crown bud; EDWIN MOLYNEUX, rich deep crimson, with golden reverse, one of the finest varieties when well grown, crown bud; EMILY TOWERS, rosy-pink, with a silver centre to the florets, which are beautifully twisted, forming a deep fine flower, height 4ft.; ERNEST CANNELL, deep fawn, florets deep, broad, and incurved, very fine, crown bud; ETOILE DE LYON, lilac-rose, florets long, broad, and reflexed, enormous flower, crown or terminal bud, though usually the best colour is found on the terminal bud; FLORENCE DAVIS, white, with green centre, fine form, crown bud; GEORGE FOSTER, rich golden-yellow, florets broad and slightly twisted as they incurve, height 4½ft.; GOLDEN SHOWER (Fig. 246), fiery yellow, florets long, narrow, and drooping, flowers small, but valuable for decoration, height 5½ft.; GRAPHIC, rosy-mauve, florets twisted and incurving, terminal bud; HENRY WEEKS, bright rich crimson, florets broad, a grand flower, height 4ft.; HERBERT J. CUTBUSH, deep red, marked with yellow, a good front row flower, crown bud; H. J. JONES, intense crimson, florets flat, broad, and handsome, height 4½ft.; JOHN POCKETT, a mixture of rich crimson and bright bronze, a deep and beautiful flower, height 4ft.; JOSEPH CHAMBERLAIN, very rich crimson, with a golden reverse to the broad florets, a seedling from E. MOLYNEUX, with a better habit and finer flower than its parent, height 4½ft.; JULIA SCARAMANZA, bronzy terra-cotta, florets long and deep, crown bud; KING OF BUFFS, salmon-buff, very large, and of good form and substance, crown bud; LADY CRAWSHAW, white, faintly shaded with pink, the florets being beautifully twisted, height 5ft.; LADY E. CLARKE, pure white sport from MRS. C. HARMAN PAYNE, and, like its parent, of large size, height 5½ft.; LADY

Chrysanthemum—*continued.*

HANHAM, golden rosy-cerise, a splendid variety, crown bud; LITTLE NELL, pure white, florets broad and deep, a fine acquisition, height 5ft.; MADAME CARNOT, pure white, very large, one of the best, crown bud; MR. A. G. HUBBUCK (Fig. 247), chestnut-red, with gold reverse, very fine, crown bud; MDLLE. THERESE REY, ivory-white, splendid when well grown, crown bud; MRS. H. WEEKS (Fig. 248), pure white, suffused with pink, a large fine flower, height 7ft., crown bud, a late variety; MRS. G. W. PALMER, deep bronze, immense flower, with broad florets, crown bud; MRS. HERMANN KLOSS, deep orange, almost bronze, very large, crown bud; MRS. C. E. SHEA, creamy-white, florets curled and twisted, very fine, crown bud; MRS. J. BEGGS, soft pink, a deep, massive new variety, of great promise, crown bud; MRS. W. H. LEES, white, tinged with pink, a deep and imposing flower, crown bud; MRS. COOMBES, rosy-mauve, florets long and drooping, an immense flower that should prove valuable for exhibition, height 4½ft.; M. CHENON DE LECHE, deep rose, florets long and drooping, extra good, crown bud; MRS. RITSON, a magnificent pure white sport from VIVIAND MOREL, this variety promises to be constant in character, height 4ft.; MRS. W. MEASE, a sulphur-yellow sport from MADAME CARNOT, height 4½ft.; MRS. WHITE POPHAM, white, shaded with carmine, florets long, drooping, and handsomely twisted, height 5ft.; MONS. PANKOUCKE (Fig. 249), clear yellow, a large deep flower, height 4ft., crown bud; MOOR PARK, golden-buff, marked with crimson, a deep flower, with long twisted florets, height 4½ft.; MONS. FATYER, soft yellow, very large and handsome, height 4½ft.; NELLIE POCKETT, creamy white, florets long, rather narrow, and twisted, a deep and lovely flower, height 5ft.; NINA DABBS, deep yellow, slightly shaded with green, florets broad and spreading, a large and deep flower, height 5ft.; NIVEUS, probably the purest white, a lovely flower, of good size, crown bud; NYANZA, dark crimson, florets incurved, must be well grown, crown bud; OLIVE OCLEE, rich deep bronze, florets incurved, good on crown or terminal buds; OWEN'S MEMORIAL, rich crimson-red, florets broad, drooping, and slightly twisted, very large, height 4ft.; PONDEROSUM, white,

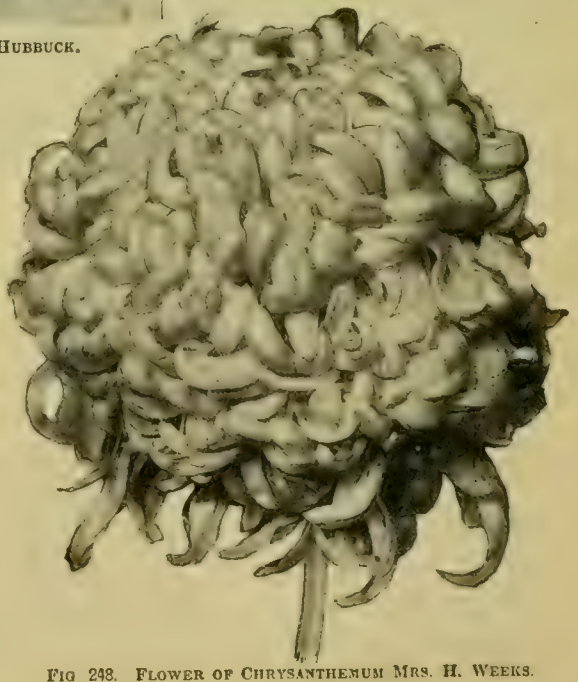

FIG 248. FLOWER OF CHRYSANTHEMUM MRS. H. WEEKS.

FIG. 249. FLOWER OF CHRYSANTHEMUM MONS. PANKOUCKE.

FIG. 250. FLOWER OF CHRYSANTHEMUM WHAT HO!

flowers of immense width and depth, terminal bud; PHŒBUS, a charming yellow, florets long and reflexed, crown bud; PRIDE OF MADFORD, crimson-cerise, a beautifully-formed flower, crown bud; R. HOOPER PEARSON, one of the best of all the yellow varieties, and of dwarf, sturdy habit in growth, a decided acquisition, height 3ft.; R. J. UPTON, canary-yellow, florets long and flat, large and distinct, height 5ft.; ROYAL STANDARD, deep crimson, flower of fine substance, very promising, crown bud; SNOWDON, pure white, of great size and beauty, crown bud; SWANLEY GIANT, lilac-pink, florets incurving, massive, crown bud; VICAR OF BRAY, crimson, shading to orange, very fine, crown bud; VIVIAND MOREL, blush-mauve, an indispensable variety, crown or terminal buds; WHAT HO! (Fig. 250), a semi-double flower of most curious form, the creamy-white florets of great length, that twist towards the points, height 5½ft.; YELLOW MADAME CARNOT, this has all the excellent qualities of the white form, crown bud.

FIG. 251. CHRYSANTHEMUM ETOILE DE LYON.

Some of the foregoing varieties being only suitable for providing very large exhibition blossoms, the following are named as excellent for supplying medium-sized flowers, most useful for cutting or decorative purposes. A lengthy description is unnecessary, and only the habit and colour of flower of each variety are given.

ANNIE CLIBRAN, pink, medium height; BOUQUET DE DAME, pure white, dwarf; ELAINE, pure white, medium height, early; ETOILE DE LYON (Fig. 251), lilac-rose, medium height; FLORENCE PERCY, white, medium height; GASPARD BOUCHARLAT, deep orange, medium height; GOLDEN DART, buttercup-yellow, dwarf, very late; KING OF PLUMES, deep yellow, medium height; LADY SELBORNE, white, medium height, early; L. CANNING, pure white, dwarf, very late; MADAME WALKER, rosy-mauve, rather tall, flowers quilled; MARGOT (Fig. 252), blush white,

FIG. 252. CHRYSANTHEMUM MARGOT.

dwarf habit; MDLLE. LACROIX, white, medium height, a favourite; M. FREEMAN, rosy-pink, dwarf; MR. CHAS. E. SHEA, yellow spot from MDLLE. LACROIX; OWEN'S BRILLIANT, deep crimson, medium height; ROSEUM SUPERBUM, salmon-pink, tall; SOURCE D'OR, deep bronze, medium height; W. HOLMES, deep crimson, dwarf; W. ROBINSON, salmon-orange, tall.

Hirsute. The Hirsute or Hairy Chrysanthemum has evidently come to stay. The following are all distinct varieties, and the plants of vigorous habit:

ABBE PIERRA ARTHUR, pure white, petals long and usually drooping, a fine large flower; BELLE DES GORDES, rich rosy-red, florets nicely incurved, fine; CAPTAIN L. CHAURE, yellow, florets incurved, a large massive flower; ESAU, salmon-blush, shading to yellow, a pretty variety; GOLD DUST, golden-yellow, florets incurved, a very pleasing flower, plants dwarf; GOLDEN HAIR, golden-yellow, the florets being very hairy; HAIRY WONDER (Fig. 253), reddish-bronze, the most massive and best hirsute variety; LOUIS BOEHMER, a shade of purplish-pink, very hairy, good habit; MADAME M. MARCHANT, rosy-pink, large flower, and plant of sturdy habit; M. FERNAND BERTIN, white, shading to red, a large, bold flower; MIDNIGHT, bronze, flower very large and very hairy; MRS. C. B. FREEMAN, golden-yellow sport from LOUIS BOEHMER; MRS. W. J. GODFREY, probably the best white hirsute variety, good habit; SOUVENIR DE L'AMI COYE, white, of good size, and dwarf sturdy habit.

Singles. These are particularly serviceable for cut flowers, being light, graceful, and remarkably free-flowering. A few varieties should be grown in every garden. Their culture is identical with that already described for bush plants. It may be stated that the Single Chrysanthemum flowers usually continue fresh longer than the other sections, and damping of the flowers very rarely occurs, even in bad weather. The following varieties may be recommended:

ALICE, white, with yellow disk, large; ANNIE HEARD, white, yellow disk, dwarf; DOLLY VARDEN, rosy-pink, flowers small, and produced in great clusters, very dwarf; DOROTHY WOODERSON, soft pink, large; D. WINDSOR, chestnut, large and fine; EMILY WELLS, lovely clear pink, very pretty, rather small; EUCHARIS, pure white, large beautiful flower, very dwarf; FRAMFIELD BEAUTY, deep crimson, extra good; GOLDEN STAR, pure yellow, large and excellent; KATE HAWTHORN, one of the finest yellows, splendid; MARY ANDERSON, white, tinged with pink, small and pretty; MISS ROSE, soft pink, small and lovely; MRS. A. E. STUBBS (Fig. 254), pure white, of fine form and great beauty, height 3ft.; REV. W. E. REMFREY, deep crimson, excellent; TERRA COTTA, terra-cotta, dwarf, and very free.

Incurved. Except for purposes of exhibition, these beautiful, though somewhat formal-shaped, flowers are losing ground; in fact, the Japanese have almost ousted the

Incurved from many gardens. Though it must be admitted that the less formal Japanese class are the more beautiful, it is more difficult to grow a really deep, well-formed flower of an Incurved variety than it is to produce a fine Japanese blossom. Not only is considerable cultural skill requisite, but a knowledge of dressing or petal manipulation is essential to have Incurved blossoms sufficiently good in character to put on the exhibition table successfully. In the list of varieties only those suitable for show purposes are named, with the bud that usually gives the best flower:

ALFRED SALTER, lilac, a deep, well-formed flower, must be grown strongly, crown bud; AUSTIN CANNELL, purple-maroon, large, and of good form, crown bud; BARON HIRSCH, chestnut-red, a well-formed, large flower, crown bud; BONNIE DUNDEE (Fig. 255), beautiful orange shade, a perfect flower when well grown, terminal bud; C. B. WHITNALL, purple, fine form, the crown bud should be selected early in August; CHAS. H. CURTIS, rich yellow, extra good and indispensable, crown or terminal buds; D. B. CRANE, bronze-buff, deep flower, of good form, terminal bud; DUCHESS OF FIFE, white, a splendid new variety, full of promise, crown bud; EMPRESS OF INDIA, pure white, a magnificent flower, but must be grown well, crown bud; GEORGE HAIGH, carmine-rose, shaded with yellow, deep flower, of good shape, crown bud; J. AGATE, pure white, deep flower, of splendid form, crown bud; JEANNE D'ARC, white, tipped with purple, a deep flower, of medium size, crown bud; JOHN FULFORD, reddish-crimson, a large flower, of good form, terminal bud; JOHN LAMBERT, pale buff, a deep and fine flower, must be grown strong, crown bud; LORD ALCESTER, pale primrose, splendid flower if grown strong, crown bud; LORD ROSEBERY, mauve, large and telling flower, terminal bud; LORD WOLSELEY, bronzy-red, a deep,

FIG. 253. FLOWER OF CHRYSANTHEMUM HAIRY WONDER.

Chrysanthemum—*continued.*

FIG. 254. CHRYSANTHEMUM MRS. A. E. STUBBS.

Chrysanthemum—*continued.*

well-shaped flower, terminal or crown buds; LUCY KENDALL, coral-red, a pretty, well-formed flower, crown bud; LYNE, JUN., golden-bronze, of good form, crown bud; MADAME DARIER, nankeen yellow, extra good shape and size, crown bud; MAJOR BONNAFFON, much in the same form and colour as CHAS. H. CURTIS, and by many is considered synonymous, crown or terminal buds; MISS M. A. HAGGAS, primrose, a lovely deep flower, crown bud; MR. JAMES MURRAY, bright pink, a fine new variety, of good substance, terminal bud; MRS. F. W. FLIGHT, white, a deep massive flower, well incurved, crown bud; MRS. HEALE, white, a medium-sized and perfect flower, crown bud; MRS. R. C. KINGSTON, soft pink or mauve, blossoms of large size, crown bud; PRINCE ALFRED, rosy-carmine, an old variety still worth growing, crown bud; PRINCESS OF WALES, blush, only good when well grown, then it is fine, crown bud; QUEEN OF ENGLAND, blush, a splendid flower when strongly grown, crown bud; ROBERT CANNELL, deep bronzy-red, very fine form, crown buds, late; ROBERT PETFIELD, silvery-mauve, large flower, well incurved, terminal bud; SIR TREVOR LAWRENCE, pure white, a massive flower, of good shape, crown bud; THE EGYPTIAN, deep red, very large, a new variety of promise; WILLIAM TUNNINGTON, reddish-chestnut, must be grown strong, terminal bud.

Reflexed. The true Reflexed Chrysanthemum has usually a moderately large flower, with the florets or petals straight and reflexing towards their points. It is neither so ornamental nor so useful as most of the other classes; and although some of the varieties are well adapted for making a display in the conservatory, they are not much admired. Only those varieties suitable for developing nice sturdy plants, with a floriferous habit, are mentioned. If four buds are retained at the point of each shoot, and all the others are removed, the plant will make a very good display for several weeks.

BOULE DE NEIGE, pure white, valuable for its late flowering; CHEVALIER DOMAGE, deep yellow, a well-known old favourite; CLARA JEAL, pure white, a new and very pleasing variety; CULLINGFORDII, crimson-scarlet, should be grown for its freedom and fine colour; DOROTHY OXBERRY, soft pink, a pleasing colour; FELICITY, creamy-white, wonderfully free-flowering and of good habit;

FIG. 255. FLOWER OF CHRYSANTHEMUM BONNIE DUNDEE.

FIG. 256. FLOWER OF CHRYSANTHEMUM GOLDEN CHRISTINE.

Chrysanthemum—*continued.*

GOLDEN CHRISTINE (Fig. 256), golden-buff, a well-known old favourite, formerly much grown; KING OF CRIMSONS, rich dark crimson, dwarf habit; MISS FLORENCE LUNN, light amaranth, flowers large and very full; PHIDIAS, rose-blush, dwarf, and an abundant blossomer; PROGNE, amaranth, violet-scented, small flower, very free; the WHITE, PINK, and PEACH CHRISTINE varieties are all three well worth growing, being of dwarf habit and free flowering (see Fig. 257).

FIG. 257. FLOWER OF CHRYSANTHEMUM PINK CHRISTINE.

Anemones. These may be divided into three sections—Japanese, Large, and Pompones, the first being the most admired, and also the most extensively cultivated. To have very fine flowers of the first two sections the plants should be carefully disbudded, leaving only one bud to each shoot; but with the Pompone class no disbudding is

FIG. 258. FLOWER OF CHRYSANTHEMUM ROBIN ADAIR.

Chrysanthemum—*continued.*

FIG. 259. FLOWER OF CHRYSANTHEMUM DELAWARE.

either necessary or desirable. The plants of these latter should be pinched or stopped several times during growth to induce a bushy habit, to be covered later with a mass of small flowers.

Japanese. BELINDA, disk rose, guard-petals dark crimson; CINDERELLA, pure white; DUCHESS OF WESTMINSTER, disk pinkish-bronze, guard-petals blush; FABIAN DE MEDIANA, disk

FIG. 260. FLOWER OF CHRYSANTHEMUM MRS. JUDGE BENEDICT.

Chrysanthemum—*continued.*

purple, guard-petals lilac; JAMES WESTON, white; JEANNE MARTY, blush-white, a very fine full flower; MABEL MILLER, white, large and excellent; MADAME CLOS, disk white, guard-petals rose; MARSIA JONES, one of the finest whites; MR. HUGH H. GARDINER, deep rose, very fine; RIDER HAGGARD, deep rose and pink, the largest Japanese Anemone; ROBIN ADAIR (Fig. 258), blush-white, tinged with lilac, an extra good variety; SOUVENIR DE MADAME BLANDINERIES, a handsome crimson; TAM O' SHANTER, rosy-lilac, a splendid flower; W. W. ASTOR, salmon-blush, one of the best.

Large. DELAWARE (Fig. 259), white, very large handsome flowers; DESCARTES, crimson, with very prominent disk, a fine variety; EMPEROR, blush, with paler centre or disk, large and good; EMPRESS, blush, disk lilac, prominent, and of good form; GEO. HAWKINS, a lovely golden-yellow; GLUCK, golden-yellow, a well-known old variety; LADY MARGARET, pure white, of fine shape, a tall grower; MADAME ROBERT OWEN, pure white, large and excellent, dwarf habit; MISS ANNIE LOW, a yellow LADY MARGARET; MISS CATERER, pure white, of splendid form and habit; MRS. C. J. SALTER, buff-orange, pretty and effective; MRS. JUDGE BENEDICT (Fig. 260), pale flesh, with a prominent lemon disk, an excellent variety, height 3ft.; NOUVELLE ALVEOLE, a shade of blush-lilac, fine flowers; ROBIN ADAIR, blush, with a good disk, fine flowers, height 4ft.; STONEACRE GEM, yellow, shading to red, excellent.

Pompones. ASTARTE, amber and gold, dwarf; CALLIOPE, ruby-red, very striking flower; EMILY ROWBOTTOM, creamy-white, fine; ERIC, deep orange-buff; MADAME MONTELS, white, yellow disk; MAGENTA KING, magenta, yellow disk; MR. ASTIE, golden-yellow, dwarf; PERLE, rosy-lilac; REINE DES ANEMONES, white, fine for cutting; VIRGINALE, white, rather large flower, valuable for its lateness.

Pompones. This class, with its small flowers borne in great profusion, should find a place in every garden where Chrysanthemums are grown; for not only are the plants of dwarf habit, and covered with blossom, but the flowers, being small, can be employed for purposes for which the large-flowered classes would be useless. A few of the best of this pretty section are as follow:

AURORE BOREALE, bronze-orange; BOB, very dark crimson; CEDO NULLI, white, golden, and lilac, three very fine varieties; COMTE DE MORNY, bright purple; FLORENCE CARR, deep bronze; HARRY HICKS, soft pink; LA PURITE, pure white, very useful for wreaths, &c.; MARION, deep orange; OUR FRED, blush-pink; PRINCE OF ORANGE, pale orange; ROSINANTE, blush, very fine; SNOWDROP, white, remarkably small flower, pretty; WILLIAM PAYNE, deep orange, dwarf and free.

EARLY-FLOWERING VARIETIES. Though the early-flowering Chrysanthemums have not made the advance in public favour that they should have done, considering their great utility alike for garden decoration and for furnishing cut flowers for home use or for market, there is strong evidence that their merits are beginning to be more fully recognised, and that their culture is extending in all directions. In time, no doubt they will occupy much of the space now devoted to plants which neither produce such a good display in the flower garden nor supply so many cut flowers for so long a period.

In forming a collection of early-flowering Chrysanthemums, it is always advisable to grow two lots of plants of the same varieties, one in pots, and another outside in a nice sunny position. The former will be extremely useful for room or conservatory decoration, and should any of the plants outside prove tender and unable to withstand the rigour of winter, or fail to throw up cuttings for propagating, their stock may be grown from the pot plants, and the risk of losing choice varieties is reduced to a minimum. Unless duplicates are thus grown, it is practically certain that losses will occur amongst the outside plants, and usually most highly-prized varieties are those to disappear.

With all early-flowering varieties the end of February or beginning of March will be quite soon enough to put in cuttings. If inserted earlier they seldom make such good or such floriferous plants as those put in later, which grow on freely without a check. In taking cuttings, it is always best to choose those shoots springing from the soil, avoiding those which may have formed on the stem below where it was cut down; the latter never make such large or vigorous plants as those struck from suckers coming through the soil. In preparing the cuttings, carefully remove a few of the lower leaves, and then insert singly in small pots, properly drained, using a sandy compost of loam and leaf-mould, in equal proportions, thoroughly mixed. Press the soil firmly about the cutting, and immediately afterwards give a good watering, which tends to settle the soil, and to prevent the foliage from flagging. A close cold frame is a very suitable

Chrysanthemum—*continued.*

place to stand the pots in, keeping it quite close until the cuttings are rooted and beginning to grow. Every care should be taken to see that the plants have sufficient water.

As soon as it is seen that the cuttings have taken root, air should be gradually admitted on all favourable occasions in order to keep the plants sturdy and strong. About the first week in April the plants may be shifted into larger pots (say large "sixties"). By the middle of May these pots will be full of roots, and the plants may be either transferred to the pots in which they are intended to flower, or they may be put out in a sunny place, where the soil has been deeply dug and well manured during the past winter. If potted, a compost of three parts fibrous loam and one part spent horse-droppings mixed together, with a little bone-meal added, will prove excellent.

Naturally, some varieties are much taller than others, and in the list appended the average height of each is mentioned, indicating which sorts are best for back and front rows respectively. A fine effect may be produced by a judicious blending of colours; or the beds in large gardens may be planted with one variety only, thus giving a mass of one colour, as is done in many of the large public parks. The plants should be supported by neat stakes early, otherwise many will be broken by the wind, and thus cause unsightly blanks in the beds. If the soil is rich and deep, and the plants are strong and healthy, 2½ft. or 3ft. between each will be a suitable distance; if the soil is poor or shallow, 1ft. less space should be given. On all soils, however, it is advisable to make fresh plantations each year.

Japanese, or **Large-Flowered.** The following varieties have proved most meritorious in a large collection:

ALBERT CHAUSSON, orange-red, very fine in pots or beds, height 2½ft.; ALFRED DROZ, soft yellow, borne in profusion, height 2ft.; BARONNE G. C. DE BRAILLES, pale pink, very large and fine, height 3ft.; COMTESSE FOUCHER DE CARIEL, orange-yellow, excellent and free, height 2ft.; CORAL QUEEN, lovely coral, a charming variety, height 3ft.; CRIMSON QUEEN, deep crimson, a great favourite, and of fine habit, height 2ft.; DE LA BOUÈRE, amaranth, large and fine, height 2ft.; DORCAS, white, bushy habit and free-flowering, height 2ft.; EDIE WRIGHT, pale pink, passing to white with age, excellent in every respect, height 2ft.; EDITH SYRATT, soft pink, wonderfully free and dwarf, height 1½ft.; GASPARD BOUCHARLAT, a lovely orange colour, produced in profusion, height 2ft.; GENERAL HAWKES, crimson-amaranth, very free, height 2ft.; GEORGE WERMIG, rich soft yellow, a well-known old favourite, height 2½ft.; HARVEST HOME, bronzy-red, tipped with gold, very handsome and free, height 2½ft.; LADY FITZWYGRAM, a splendid early white, height 2ft.; MADAME DESGRANGES, white, well known for its excellence, height 2½ft.; MADAME EULALIE MOREL, a beautiful cerise and gold, height 3ft.; MADAME MARIE MASSE, lilac-mauve, one of the best, height 2ft.; MYTCHETT WHITE, snowy white, a magnificent variety, height 1½ft.; PREFET CASSAGNEAU, deep crimson, fine habit, height 2ft.; RYECROFT GLORY, deep orange, most effective, height 1½ft.; SAM BARLOW, a charming salmon-pink, very free, height 3ft.; THE DON, lilac, profuse and early, height 2ft.; VICE-PRESIDENT HARDY, deep red, good habit, height 3½ft.

Pompones. The small compact-flowered Pompone varieties are greatly admired by many, and are extremely useful for cutting purposes or for massing in beds. Amongst the many varieties in commerce, the following may be described as of high merit:

ALICE BUTCHER, red, shaded with orange, excellent, height 2½ft.; ANASTASIO, pale purple, very dwarf and bushy, height 1½ft.; BLANCH COLOMB, ivory-white, free and pretty, height 2ft.; CANARI, yellow, flowers in great abundance, height 1½ft.; EARLY BLUSH, soft blush, very fine variety, height 2ft.; FREDERICK PELE, crimson and gold, makes an effective bed, height 3ft.; GOLDEN FLEECE, straw-yellow, one of the best of its colour, height 2ft.; L'AMI CONDERCHET, primrose, probably the best Pompone, height 1ft.; LONGFELLOW, pure white, splendid for cutting or for beds, height 2½ft.; MADAME JOLIVART, white, tinged with pink, very pretty, height 2ft.; MRS. CULLINGFORD, white, excellent, height 3½ft.; MISS DAVIS, soft pink, a sport from MRS. CULLINGFORD, but dwarfer; M. JULES PAQUET, white, and violet-rose, height 1ft.; MR. SELLEY, a blush-white, very pretty and effective, height 1½ft.; PIERCY'S SEEDLING, deep yellow, wonderfully free, height 2ft.; SILVERSMITH, white, of large size, a most useful variety, height 3ft.; STRATHMEATH, a soft rosy-pink, excellent, height 2ft.; TOREADOR, a rich crimson and gold, height 2½ft.; YELLOW L'AMI CONDERCHET, deep yellow, sport from L'AMI CONDERCHET.

INSECT AND OTHER PESTS. Aphides are amongst the most destructive insects infesting Chrysanthemums, and

Chrysanthemum—*continued.*

they multiply very rapidly. Frequently they are present in incredible numbers, though the "green-flies" at any rate approximate so closely to their surroundings that they are not so readily seen as the "black-fly" (*Aphis rumicis*), which is also troublesome. Under glass, the new vaporising insecticides are the best remedies to employ: they are easily applied, and very effective and cheap. Before using any insecticide it will be well to remove any of the Ladybirds and their larvæ, the leech-like larvæ of Hawk-fly (*Syrphus*), or even the gaily-apparelled, if gauzy-looking, Lace-wing Flies. They are the natural enemies of Aphides, and will consume vast numbers in a short time. Outdoors, a weak solution of carbolic soft-soap will be sufficient to cleanse the plants of "green-fly" and "black-fly," both of which species, as already stated, are at times troublesome. This will be rendered more effective if applied lukewarm.

Earwigs are most destructive at times to Chrysanthemum blossoms, and in a single night will disfigure the best of flowers, rendering them quite unfit for show. They should always be trapped with loosely-rolled tissue-paper, old dusters laid in the vicinity of the plants, or by means of an inverted flower-pot half-filled with hay and stood upon the stakes. It may here be stated that Earwigs, though as a rule vegetarians and destructive to many plants, occasionally forsake such a diet for one of flesh, and then they even render the gardener service by devouring Aphides, Thrips, and other injurious pests.

Occasionally the leaves of Chrysanthemums and closely-allied plants suffer from the attacks of that plague of the Marguerite-grower, *Phytomyza affinis*. This fly deposits its eggs upon the foliage; the larvæ are in due time hatched out, and feed between the two surfaces. Their presence is revealed by a blister-like swelling and by white or light-coloured zigzag tracks over the leaves. Feeding as they do, the pests are difficult to eradicate by means of insecticides; but, by way of prevention, the leaves of the plants may be sprayed with a weak emulsion of paraffin or with a quassia-chip solution; or fumigation will make the leaves distasteful to the perfect insect. The old-fashioned method of squeezing the insects between finger and thumb has much to recommend it. Sometimes plants are so badly attacked that nothing short of removing and burning the infested leaves is of any use.

Thrips are sometimes destructive to the shoots, but they may be destroyed by syringing them with the preparation suggested for Aphides on outside plants.

Ants are injurious to the buds, and will penetrate them if but a beginning has been made. They should be trapped by means of pieces of sponge dipped into a sweet liquid or by some bones containing a little meat. In the latter case the insects should be brushed off into boiling water, while in the former the sponge should be dropped into a vessel of boiling water.

Cockroaches of several kinds attack the blossoms, though on account of their night-feeding propensities they are seldom seen, and less often suspected. Heat, however, being absolutely necessary to the welfare of these insects, it is only where this is applied that Cockroaches are really troublesome. Phosphorus paste or the Ballinkin-rain Ant Destroyer may be employed in keeping down these insects.

Woodlice, like the Cockroaches, will considerably damage the blossoms. As a rule, they are strong in numbers, and once thoroughly established, they are difficult to oust. Vegetable traps, in the form of sliced or hollow potato, may be tried; but usually flower-pots half filled with hay and turned upon their sides are the most effective, as the Woodlice shelter there after their midnight revels, and may easily be shaken out and destroyed. More effective still is the trap where the inside of the pot is smeared with a sugary mixture composed of treacle, foots-sugar, and beer.

Slugs infest the Chrysanthemum, and take toll of the blossoms. They are nocturnal, and should be enticed with bran or brewers' grains, and then collected and destroyed.

Leather-jackets are the destructive larvæ of the Crane-fly, or Daddy Long-legs. They abound in pastures and lands, and therefore they may be readily introduced with the potting-soil. They feed for a long time as larvæ, and would quickly destroy the roots of any Chrysanthemum. The soil should be carefully examined at potting-

Chrysanthemum—*continued.*

time, and if any of the insects are noticed they should be destroyed.

Mildew, though not a formidable fungus disease like Leaf-Rust, described below, is undesirable, and has a debilitating effect upon its host-plant. The Mildew usually found upon Chrysanthemums is due to the presence of a specific fungus, *Oidium chrysanthemi*, a relative of that pest of the Vine, *Oidium Tuckeri*. Powdered sulphur, or better still, spraying with sulphide of potassium of the strength recommended for Leaf-Rust, will be found effectual, especially if combined with plenty of light and air, and fluctuations of temperature are avoided.

Leaf-Spot (*Septoria chrysanthemi*) is a disfiguring and weakening fungus disease characterised by dark brown spots on the foliage. They are at first small, but gradually increase in size, and the leaves fall. Spraying, as before recommended, is the remedy.

The condition of the blossoms popularly described as "damping" is too well known. Frequently it is present with the Mildew attack above noted, the conditions of the atmosphere being favourable for the development of either. Chrysanthemums in foggy towns are more liable to the condition than those grown where fogs are comparatively light. An atmosphere surcharged with moisture is also fatal, and therefore a buoyant one should prevail. Another prolific source of "damping" is due to the use, or rather to the abuse, of stimulants.

CHRYSANTHEMUM LEAF-RUST (*Puccinia hieracii*). Within the last year or so growers of Chrysanthemums have suffered not a little from the ravages of this destructive Rust-fungus. In several cases, practically whole collections have been destroyed, and in a great many more the loss has been extremely heavy. The generic name at once singles the pest out as a near relative of the much-dreaded Hollyhock fungus, and the specific one suggests that it is not the Chrysanthemum alone that it affects, but the Hawkweeds, many of which are among the commonest wayside flowers. It is necessary—indeed, important—to know this, as it to a certain extent accounts for the transference of the Rust by various agencies from weeds to cultivated plants. Nor are the Hawkweeds alone host-plants of the pest. Burdock, Knapweed, Thistle, and Groundsel are quite as commonly infested.

The Rust is found occasionally on the upper-surface as well as upon the under-surface of the leaves, which after a time are found to be covered with a number of brownish spots of varying size. Sometimes such spots are separate, at others they coalesce, until practically the whole leaf is involved; finally the leaf assumes a still more unhealthy hue—first yellow and then brown—and falls. Prior to this latter stage, however, the numberless spores which have formed have been distributed over an extended surface. Then it is that the parasite is readily carried by insect and other agencies into non-infected areas. In fact, a collection which, say a week or so before, presented a healthy appearance and without the slightest trace of fungus, could practically be ruined in that short time. First one plant, then another, become involved, and the collection goes from bad to worse. The actual time occupied by one of the spores in developing, once it has found a congenial resting-place, varies, but from eight to ten days at most would probably cover it.

Here it may be well to state that the first manifestations of the disease to the gardener are usually the formation of the now familiar Rust. Long ere this, however, the insidious pest has been working unseen on the leaf-tissues by means of mycelium. In fact, the "Rust" is the outward and visible sign that one kind of fruit has been matured—that known as uredospores, or summer spores—and it is by means of this that the area of infestation is increased. This is where the value of spraying comes in, as it prevents such spores as fall, or are carried upon the foliage, from germinating.

If spraying with a fungicide be not adopted, then later in the year (towards autumn) other spores are produced. These are named teleutospores. By means of these the plant-disease is usually carried over the winter, though in certain cases it may be continued by means of the summer spores. The grower would therefore be wise to burn such plants before they have arrived at the stage when the winter spores are formed. If this be not done the teleutospores are dispersed in various ways, many falling

Chrysanthemum Leaf-Rust—*continued.*

upon the soil. They will not germinate the same season, but they assuredly will do so in the ensuing spring, commencing again the cycle of life, unless the grower sprays his plants from the earliest times.

There is absolutely no cure when once the Leaf-Rust fungus has asserted itself. It is, however, possible to stay its progress by spraying with sulphide of potassium (a common fungicide with rosarians and others), at the rate of 1oz. to 3galls. of water, used lukewarm. This will destroy the spores before they can enter the foliage. Affected plants should also be isolated. As a precautionary measure, too, growers would be well advised to spray periodically—say, every eight or ten days—throughout the season. Still, notwithstanding the spraying, some of the spores will doubtless find a suitable resting-place. Where, therefore, the disease has been known to exist, very great care should be exercised by the gardener in collecting every leaf and stem from plants which have been infested, and instead of consigning them to the rubbish-heap they should be burned, otherwise next season the chances are that a severer attack will be experienced.

CHRYSANTHEMUM LEAF-SPOT. *See* **Chrysanthemum.**

CHRYSEIS. A synonym of **Eschscholtzia** (which *see*).

CHRYSIPHIALA. Included under **Stenomesson** (which *see*). *C. latifolia*, however, is a synonym of **Urceolina latifolia.**

CHRYSOBAPHUS. A synonym of **Anœctochilus** (which *see*).

CHRYSOBOTRYA. Included under **Ribes** (which *see*).

CHRYSOCEPHALUM. A synonym of **Helichrysum** (which *see*).

CHRYSOCOMA LINOSYRIS. *See* **Aster Linosyris.**

CHRYSOGLOSSUM (from *chrysos*, yellow, and *glossum*, a tongue; in allusion to the colour of the lip). ORD. *Orchideæ*. A small genus (four or five species) of stove, terrestrial Orchids, with the habit of *Tainia*, natives of India and Malaya. Flowers mediocre, shortly pedicellate, disposed in a lax raceme; pollen masses two, free. Pseudo-bulbs narrow or wanting, one-leaved. *C. villosum* is in the Kew Collection. For culture, *see* **Calanthe.**

C. villosum (villous). *fl.* yellow, banded with purple, villous, ¾in. in diameter; lateral sepals decurved; petals curved upwards; mid-lobe of lip panduriform; scape (with raceme) 1ft. to 2ft. long. *l.* solitary, 6in. to 12in. long, broadly elliptic or ovate, villous; petiole 1in. to 2in. long. Perak and Java.

CHRYSOMELIDÆ. *See* **Phyllotreta.**

CHRYSOPA VULGARIS. *See* **Lacewing Flies.**

CHRYSOPHYLLUM. SYNS. *Cainito, Nycteristion.* This genus comprises about sixty species, mostly tropical American, a few being found in Africa, tropical Asia, Australia, and the Sandwich Islands. To those described on p. 325, Vol. I., the following should be added:

C. imperiale (imperial). *fl.* yellowish-green, fascicled at the sides of a branch as thick as the finger, pedicellate; corolla subrotate, five-lobed. April. *fr.* the size of a small Apple, obtusely five-angled. *l.* 3ft. long, 10in. broad, petiolate, obovate-oblong or oblong-oblanceolate, acute or obtuse, deeply serrated. Brazil. (B. M. 6823.) SYN. *Theophrasta imperialis* (I. H. xxi. 184; R. G. 1864, 453).

CHRYSORRHOË. Included under **Verticordia** (which *see*).

CHRYSOSTEMMA. Included under **Coreopsis** (which *see*).

CHRYSOTHAMNUS. A synonym of **Bigelovia** (which *see*).

CHRYSOTHEMIS. A synonym of **Tussacia** (which *see*).

CHRYSOXYLON. A synonym of **Pogonopus** (which *see*).

CHTHAMALIA. A synonym of **Lachnostoma** (which *see*).

CHUSQUEA (said to be the native name of some of the species in the West Indies). SYNS. *Dendragrostis, Rettbergia.* ORD. *Gramineæ*. A genus embracing about thirty species of suffruticose or arborescent, sometimes climbing, American Grasses. Flowers in terminal panicles; spikelets one-flowered, variously paniculate. Leaves often rather small for the tribe (*Bambuseæ*), flat, articulated with the sheaths. *C. abietifolia*, the only species known to cultivation in this country, is an interesting and graceful, stove, climbing Bamboo. It thrives in well-drained loam, and is propagated either by means of imported seeds or by division of the rootstock.

C. abietifolia (Abies-leaved). *fl.* in racemes, terminating the leafy branches; spikelets green and purple, ¼in. to ½in. long, December. *l.* ½in. to ⅔in. long, ⅛in. broad, strict, erect, sessile on the sheath, linear-lanceolate, acuminate. Stems wiry, smooth, terete. Jamaica, 1885. (B. M. 6811.)

CHYLODIA. A synonym of **Wulffia** (which *see*).

CHYSIS. The cultural requirements of these Orchids are a light position in the warm intermediate or Cattleya house, and during the growing season an abundant supply of moisture, both at the roots and in the atmosphere. After growth has become matured less moisture and lighter and more airy conditions should prevail. Full exposure to the autumn sun in a vinery, where the leaves have fallen, suits them admirably. The pots used should be drained to two-thirds their depth with clean broken crocks, and the potting compost may consist of fibrous peat and sphagnum, with a liberal sprinkling of rough sand or broken crocks. The best season to pot is when the young growths commence to emit new roots from their base.

The six or eight species referred to this genus are natives of Mexico and Colombia. To those described on pp. 326-7, Vol. I., the following should be added:

C. aurea maculata (spotted). *fl.*, sepals and petals tawny-yellow, zoned with purple, white at base; side lobes of lip yellow, stained brownish-purple at base, the middle lobe purple with pale markings. Venezuela, 1850. (B. M. 4576.)

C. Bruennowiana (Bruennow's). *fl.* of a pinkish hue, medium-sized. Peru, 1893. This closely resembles *C. aurea* in habit, but is regarded as a distinct species. SYN. *C. Oweniana.*

C. Limminghei (Comte Alfred de Limminghe's). *fl.* 2in. across; sepals and petals white, with a purple blotch at apex; side lobes of lip reddish-purple and yellow inside, pale buff-yellow outside, incurved towards the column, the middle lobe bright purple, streaked with yellow, emarginate; column white above, yellow spotted with red opposite the lip. Tabasco, Mexico, 1857. This is now classed as a distinct species. (B. M. 5265, as a var. of *aurea*; I. H. 1860, t. 240; W. S. O. i., t. 34.)

C. Oweniana (Owen's). A synonym of *C. Bruennowiana.*

C. undulata (wavy). *fl.* ten to twelve in a raceme; sepals and petals of a lively orange-yellow; lip cream-coloured, marked with numerous lines of pink. Pseudo-bulbs 1½ft. high. Native country unknown. A rare but handsome species.

The following are hybrids:

chelsoniensis ..... *bractescens* and *lævis* (Veitch).
langleyensis ..... *bractescens* and *Sedenii* (Veitch).
Sedenii ..... *Limminghei* and *bractescens* (Veitch).

CHYTROGLOSSA (from *chytros*, a well, and *glossa*, a tongue; in allusion to the hollow at the base of the lip). ORD. *Orchideæ*. A small genus (two species) of stove, epiphytal Orchids, with very short stems, natives of Brazil. Flowers mediocre, shortly pedicellate; sepals and petals similar, free, spreading; lip continuous with the base of the column, obscurely three-lobed, with one or two callosities at base; column short; raceme recurved or pendulous. Leaves sub-distichously fascicled, oblong-elliptic or linear, flat. These plants should be grown on blocks, in a hot, damp stove.

C. aurata (golden). *fl.*, sepals green and yellow, petals white, the base of the column and lip spotted with purple; dorsal sepal and petals forming a kind of helmet over the column; raceme glaucous, zigzag. *l.* few, lanceolate, acute, 2in. to 3in. long. 1865. (J. H. S. ser. ii., vol. i., t. 3.)

Chytroglossa—*continued.*

C. Marileoniæ (Marie Léonie's). *fl.* having a three-lobed lip, with a two-starred callus at base. Otherwise resembling *C. aurata.* 1865.

CICATRICE, CICATRIX. The scar left by a falling leaf or other organ.

CICELY, SWEET. *See* **Myrrhis odorata.**

CICENDIA (a name of doubtful derivation). ORD. *Gentianeæ.* A monotypic genus. The species, *C. pusilla*, is a dwarf, much-branched annual, native of Western Europe (Britain), with small, pink, white, or pale yellow flowers; it is of no horticultural value.

CICER (from *kikos*, strength; in allusion to the properties anciently attributed to the seeds). ORD. *Leguminosæ.* A small genus (about seven species) of stove or greenhouse, annual or perennial herbs, natives of the Mediterranean region and West and Central Asia. *C. arietinum* (Chich Pea) is widely cultivated as pulse, but has no horticultural value (B. M. 2274).

CICINDELA CAMPESTRIS. *See* **Tiger Beetles.**

CIDARIA. A genus of Moths, several species of which are hurtful in gardens. The commonest are *C. associata* (*C. dotata*, Gn.) and *C. prunata* (*C. ribesiaria*). The larvæ of the former feed upon Currants, and those of the latter upon both Gooseberries and Currants. The perfect insects of *C. associata* are about 1½in. in wing-expanse, and are flying in July. The fore-wings are pale ochreous yellow, with three reddish-brown zigzag lines—two before and one behind the middle. The hind-wings are much paler. The larvæ are slender, pale green, with a pale yellow stripe on each side; they are feeding during May and June.

C. prunata is rather larger than *C. associata*, but has brown fore-wings, with indistinct darker striæ, and grey hind-wings. It is on the wing in July. The larva is green or brown, with a darker brown white-spotted ring, and some whitish triangular spots bordered with brown. It feeds in May and June.

C. fulvata (Barred Yellow Moth) is a third species, not so common in gardens, but nevertheless destructive to Roses. The Moth itself is about 1in. in wing-expanse; it has bright yellow fore-wings, with basal patch rusty red, and having a wavy edge; there is also a middle reddish band suffused with a darker colour, as well as a yellow costal blotch. The hind-wings are whitish-yellow. The larva is found in May and June; it is pale green, with darker green dorsal lines and yellow stripes at side.

As these are chewing insects, the bushes had better be sprayed with Paris Green (1oz. to 20galls. of water), taking care that in the case of the Gooseberries and the Currants the fruit is not required for culinary purposes until some time after. Or powdered hellebore, if dusted on in the early morning, will be similarly efficacious; but this, too, is a powerful poison, and must be used with care.

CIENFUEGIA. A synonym of **Fugosia** (which *see*).

CIENFUGOSIA. A synonym of **Fugosia** (which *see*).

CIMICIFUGA PALMATA. A synonym of **Trautvetteria palmata** (which *see*).

CIMINALIS. A synonym of **Gentiana** (which *see*).

CINCHONA. Quina; Quino; Quinquina. SYN. *Kinkina.* Thirty-six species are comprised in this genus. To those described on p. 327, Vol. I., the following variety should be added:

C. Calisaya Josephiana (Joseph de Jussieu's). A very distinct variety, with whitish, very fragrant flowers. Bolivia and Peru, 1866. (B. M. 6052.)

C. Condaminea (Condaminea). A synonym of *C. officinalis.*

CINERARIA. SYN. *Xenocarpus.* Of the twenty-five species included in this genus, twenty-two are natives of South and three of tropical Africa. Leaves alternate or radical, often broad and incised-toothed or variously pinnatisect, rarely entire. To the species and varieties described on pp. 329-30, Vol. I., the following should be added. Several plants formerly included here are now referred to **Senecio.**

C. albicans (whitish). *fl.-heads* clear yellow, ¼in. to ⅜in. in diameter; corymb terminal, few-headed. *l.* somewhat reniform or nearly circular in outline, cordate at base, five- to seven-

Cineraria—*continued.*

lobed; lobes equally trilobulate and many-toothed. Stems 1ft. to 1½ft. high, clothed with cottony tomentum. Natal, 1895. Half hardy.

C. aurita (eared). A garden synonym of *Senecio Heritieri.*

C. cruenta. The correct name is *Doronicum cruentum.*

C. gigantea (gigantic). A synonym of *Senecio Smithii.*

C. lanata (woolly). A synonym of *Senecio Heritieri.*

C. longifolia. The correct name is *Senecio brachychætus.*

C. Lynchii (Lynch's). A garden hybrid between *C. multiflora* and *C. cruenta.* 1897.

C. maritima. The correct name is *Senecio Cineraria.*

C. m. aureo-variegata (golden-variegated). *l.* green, margined with creamy-yellow. 1893. A pretty variety. (J. H. xxvi., p. 438, f. 78.)

C. m. candidissima (whitest). In this variety the foliage is remarkably white and compact.

CINNAMODENDRON. A couple of species form this genus, one being a native of the Antilles and the other Brazilian. Bracts three; sepals and petals four or five, sub-equal; cymes few-flowered. For culture, *see* **Canella.**

CINNAMOMUM. *Camphora* is included in this genus by the authors of the "Genera Plantarum." *C. Camphora* is the correct name of *Camphora officinalis.* The following species is worth description:

C. zeylanicum (Cingalese). Cinnamon-tree. *fl* yellowish-white, in terminal racemes. *fr.* berry-like. *l.* opposite, petiolate, ovate-oblong, entire, coriaceous, glabrous, 3in. to 4in. long. *h.* very variable. Ceylon. SYN. *Laurus Cinnamomum.*

CIONIDIUM. *See* **Deparia.**

CIPURA. SYN. *Marica* (of Schreber). *C. martinicensis* is synonymous with *Trimezia martinicensis.*

CIRCUMCISED. Divided in a transverse, circular manner.

CIRRHÆA. *C. saccata* (B. M. 3726) and *C. viridi-purpurea* (B. M. 2978) are included among the Kew collection of Orchids; but, as observed on p. 330, Vol. I., the species of this genus are rarely seen in cultivation.

CIRRHOPETALUM. SYNS. *Hippoglossum, Zygoglossum.* The species of this genus are mostly natives of the East Indies (thirty-eight are described in Hooker's "Flora of British India") or the Malayan Archipelago; one is found in the Mascarene Islands, another in China, and a third in Australia. To those described on pp. 330-1, Vol. I., the following should be added:

C. Amesianum (Hon. F. L. Ames's). *fl.* rather large, six to ten in a nodding spike; lateral sepals yellowish-white, shaded with rosy-purple at the base, united; dorsal sepal and petals yellow, fringed with reddish-brown; lip reddish-brown; scapes nodding. *l.* broad. Pseudo-bulbs quadrangular. Tropical Asia. (L. vii., t. 314.)

C. appendiculatum (having an appendage). *fl.* solitary, about 8in. long; upper sepal white, with three purple lines, and bearing at the apex a long, slender, purple plume; petals white, with one purple line, and a brush-like plume at the end of each; lip of two shades of bright purple, thick, tongue-like, and the long, lower sepals whitish with purplish marks, and united (or so closely placed as to appear to be so), each finishing up in a slender point Bengal, 1898. A most remarkable species. (G. C. 1898, ii. pp. 391, 415, f. 118.)

C. Blepharistes (eyelid-like). *fl.*, lateral sepals pale yellowish-green, with faint red nerves, coherent, 1in. long; petals yellow, tipped with red; raceme short, erect, dense-flowered. *l.* 2in. to 3in. long, oblong, very thick. Pseudo-bulbs 1½in. to 3in. long, oblong. Khasia, &c.

C. brevipes (short-stalked). *fl.* rose-pink, three to four in an umbel; lateral sepals free, 1in. long; scape ½in. to 1in. long. *l.* 2in. long, linear-oblong. Pseudo-bulbs erect, 1in. to 1½in. long. Rhizome long and slender. Sikkim Himalaya.

C. cæspitosum (tufted). *fl.* pale ochreous-yellow, cellular or papillose; lateral sepals ⅜in. long; umbel few-flowered. April. *l.* 4in. to 6in. long, linear- or oblong-lanceolate. Pseudo-bulbs ovoid. Khasia, &c., 1837.

C. Collettii (Collett's). *fl.* dark purple and yellow; dorsal sepal ⅜in. long; lateral ones 4in. to 5in. long, with filiform tips; umbel many-flowered; scape 3in. to 6in. long, very robust. *l.* 1in. to 1½in. long, sessile ovate to elliptic-oblong, thick. Pseudo-bulbs very small. Rhizome very stout. Eastern Birma, 1891. The largest and most beautiful of the Indian species. (B. M. 7193.)

Cirrhopetalum—*continued.*

C. compactum (compact). *fl.* pale straw-yellow, small, sub-umbellate, nodding; lateral sepals about ¼in. long. September. *l.* 1in. to 1¼in. long, elliptic-oblong, fleshy, sessile. Pseudo-bulbs ½in. long. Tenasserim, 1895.

C. cornutum (horned). *fl.* arranged in a radiating umbel; lateral sepals reddish-brown, 1½in. long, convex, coherent; dorsal sepal and petals green, blotched with purplish-brown; scape long and slender. *l.* 6in. to 10in. long, linear-oblong. Pseudo-bulbs 1in. to 5in. long, ovoid or columnar. Sikkim and Khasia, 1852. A pretty and curious species. (B. M. 4753.)

C. Curtisii (Curtis's). *fl.* white, pink, and yellow, small, disposed in an umbel; scape 4in. long. *l.* linear-oblong, 4in. long. Pseudo-bulbs ovoid, ½in. long. Rhizome flexuous. Malacca, 1897. Allied to *C. Cumingii*. (B. M. 7554.)

C. elegantulum (somewhat elegant). This is described as a species "too small to be showy, though the flowers are pretty enough, being striped with maroon-purple on a pale ground." Madras, 1891.

C. fimbriatum (fringed). *fl.* green, with long red cilia to the petals; lateral sepals 1in. to 1½in. long; umbels many-flowered. April. Pseudo-bulbs globose, smooth, leafless when flowering. Bombay, 1838. (B. M. 4391.)

C. Gamblei (Gamble's). *fl.* yellow, streaked and dotted with red; lateral sepals ½in. long; scape 1in. to 2in. long, very slender. *l.* 1in. to 2in. long, linear-oblong or -lanceolate. Pseudo-bulbs ½in. long, ovoid. Nilghiri Hills.

C. gamosepalum (with united sepals). *fl.*, dorsal sepal and petals bright red, the lateral ones speckled with purple, ¾in. long and at first coherent, at length widely divergent; scape slender, 4in. long. *l.* 2in. to 5in. long, linear-oblong or oblanceolate. Pseudo-bulbs 1in. to 1½in. long. Tenasserim, &c.

C. gracillimum (very slender). *fl.* reddish-purple, in shape like those of *C. vaginatum*; lateral sepals 1½in. long; scape slender, 6in. to 7in. long. *l.* 2½in. long, oblong, attenuated at base. Pseudo-bulbs ¾in. long, tetragonal-ovoid, one-leaved. Rhizome creeping. Birma (?).

C. grandiflorum (large-flowered). *fl.* purple; sepals acuminate, the lateral ones 2in. long, the dorsal one cymbiform, ciliated; scape as long as the leaves, stout. *l.* 3in. to 5in. long, linear-oblong, shortly petiolate. Pseudo-bulbs conical. Ceylon, 1895.

C. graveolens (strongly-scented). *fl.* strongly scented; sepals and petals yellowish-green, speckled with red; lip reddish-brown, changing to deep purple; raceme 7in. across, about thirteen-flowered; scape 6in. high. *l.* 1ft. long, 5in. broad. New Guinea, 1896.

C. guttulatum (slightly striped). *fl.*, sepals yellowish or greenish, speckled with purple, spreading, the lateral ones ½in. to ¾in. long; lip short; umbel few-flowered; scape 6in. to 10in. long, sprinkled with purple. *l.* 6in. to 10in. long. Pseudo-bulbs 1in. to 2in. long, ovoid. Sub-tropical Himalaya, 1837. (B. M. 4267.) SYN. *Bulbophyllum umbellatum* (B. R. 1844, t. 44).

C. Lendyanum (Lendy's). *fl.* whitish, with a greenish-yellow hue; lateral sepals free, twice as long as the ligulate, acuminate upper one; petals ligulate, acuminate; lip compressed, bicarinate on the narrow upper side; raceme umbellate. *l.* cuneate-oblong, acute, minutely bilobed, purple beneath. Pseudo-bulbs pyriform-tetragonal, reddish. 1887.

C. Macræi (Macrae's). *fl.* between umbellate and racemose; sepals pale yellow and scarlet, the lateral ones 3in. long, coherent, with long, filiform tips; scape 6in. long, very slender. April. *l.* 3in. to 5in. long, oblong, petiolate. Pseudo-bulbs scarcely as large as nutmegs. Ceylon, 1839. (B. M. 4422.)

C. maculosum (spotted). *fl.* pale yellowish-green, unspotted [*sic*], two to five in an umbel; lateral sepals ½in. to ¾in. long; scape stout, 2in. to 3in. long. *l.* 5in. to 6in. long, linear, notched. Rhizome slender. Western Himalaya, 1841.

C. Makoyanum (Makoy's). *fl.* pale yellow, dotted with red, 1½in. long, twelve to fourteen in a star-like umbel; scape very slender, erect, reddish-brown. January. *l.* oblong-oblanceolate. Pseudo-bulbs sparse, narrow-pitcher-shaped. Rhizome robust, creeping. East Indies (?), 1892. (B. M. 7259.)

C. Mastersianum (Dr. Masters'). *fl.* deep yellow, 1½in. long, with the upper half of the lateral sepals brown and the lip brownish-purple; umbels six- to eight-flowered, borne on purplish, drooping scapes. *l.* 4in. to 5in. long, 1in. broad. Pseudo-bulbs ovoid-quadrangular, one-leaved. Dutch Indies, 1890. (L. vi., t. 255.)

C. Medusæ. The correct name is *Bulbophyllum Medusæ*.

C. mysorense (Mysore). *fl.* almost white, except the lip, which is purple; lateral sepals ½in. long; scape 3in. to 4in. long. September. *l.* 3½in. long, linear-oblong, attenuated at base. Pseudo-bulbs ¾in. to 1in. long, tetragonal-ovoid, one-leaved, distant. Hills of Mysore, 1891. Allied to *C. maculosum*.

C. nodosum (having prominent nodes). *fl.* densely speckled with reddish-brown on a darker ground, sub-racemose, 1½in.

Cirrhopetalum—*continued.*

long; scape 3½in. long, six- or seven-flowered. *l.* 5½in. long, linear-oblong, narrowed at base. Pseudo-bulbs distant, the intervals on the rhizome showing several thickened nodes. Southern India, 1892. Allied to *C. Macræi*.

C. Obrienianum (O'Brien's). *fl.* yellow and maroon, small, borne on a scape 9in. long. *l.* oblong, 2¼in. long. Pseudo-bulbs ovoid, ½in. long. Borneo, 1893. Allied to *C. Makoyanum*.

C. ornatissimum (very ornate). *fl.* pale yellow, streaked and stained with purple, about the size of those of *C. Thouarsii*;

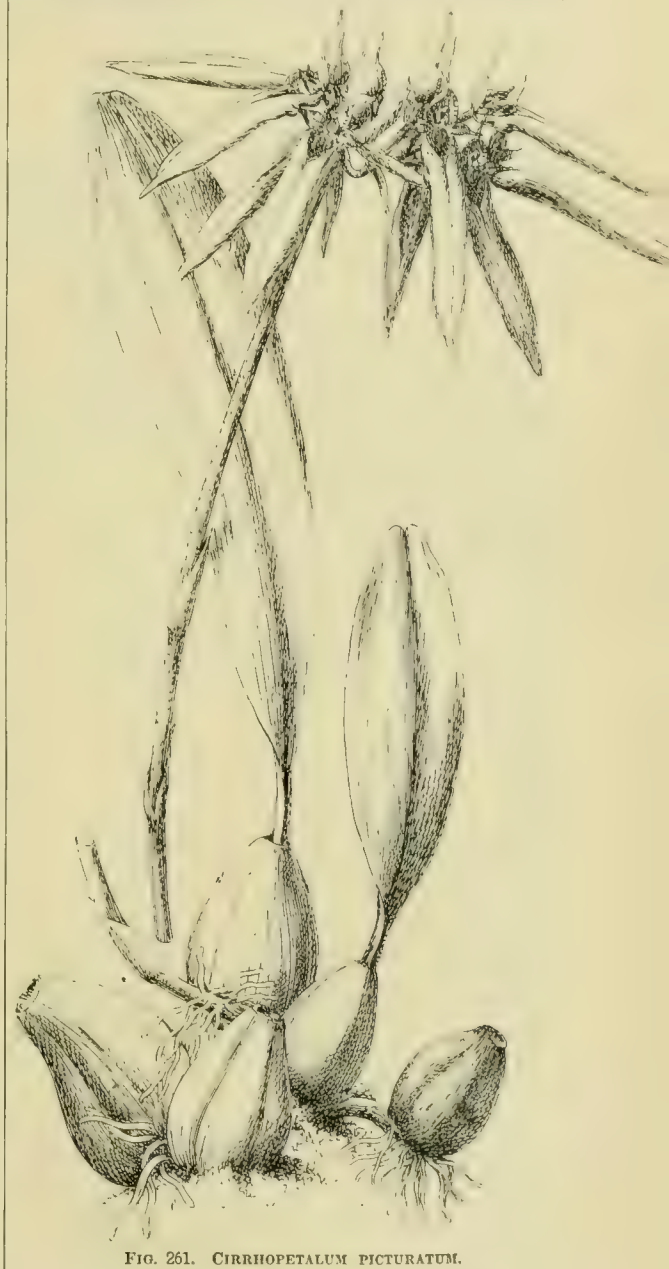

FIG. 261. CIRRHOPETALUM PICTURATUM.

dorsal sepal fringed at apex, the lateral ones prolonged into slender tails; lip deep purple, reflexed, with a curved claw; umbel four- or five-flowered; scape short. *l.* oblong, 4in. to 5in. long. Pseudo-bulbs ovoid, 1in. to 1½in. long. Sikkim Himalaya, 1889. (B. M. 7229; W. O. A., t. 369.)

Cirrhopetalum—*continued.*

C. picturatum (adorned). *fl.* 2in. or more in length; upper sepals ½in. long, with a terminal, purple thread ½in. long; lateral sepals connivent in a pale, dirty green, convex blade; petals very small; umbel about ten-flowered; scape green, speckled with purple, 8in. to 10in. long; sheaths speckled red. *l.* solitary, 3in. to 6in. long, 1½in. broad, linear-oblong. Pseudo-bulbs tufted. Moulmein, 1885. See Fig. 261. (B. M. 6802.)

C. pulchrum (beautiful). *fl.*, dorsal sepal purple, dotted with fuscous-purple, the lateral ones connate in a yellow, purple-blotched, linear-oblong, obtuse lamina, 1½in. long; petals purple, falcate; lip purple, linear-oblong, recurved; pedicels ½in. long; umbel about seven-flowered; scape erect, 4in. to 5in. long. *l.* oblong, obtuse and emarginate at apex, narrowed at base, thick. Halmahera, 1886.

C. refractum (bent back). A synonym of *C. Wallichii.*

C. robustum (robust). *fl.* 2½in. long; sepals and petals greenish-yellow, tinged with purple; lip deep reddish-purple; scape very stout, bearing an eleven-flowered umbel 7½in. across. *l.* thick and leathery, 13in. long, 4in. broad. Pseudo-bulbs large, ovate, angled. New Guinea, 1893. Probably the largest species known. (B. M. 7557; G. C. 1895, ii., p. 771, f. 116.)

C. Rothschildianum (Hon. W. Rothschild's). *fl.* bright crimson-purple, blotched with yellow on the sepals. Pseudo-bulbs ovate or pyriform. Darjeeling, 1895. A new species, closely allied to *C. Collettii.* (G. C. 1895, xviii., p. 608, f. 102.)

C. setiferum (bristle-bearing). *fl.* umbellate, 2in. long; sepals and petals bristly; scape slender, 9in. to 10in. long, four- to six-flowered. August. *l.* 9in. to 10in. long, narrow-oblong, obtuse. Pseudo-bulbs 1in. long, 1in. to 2in. distant. Himalayas, 1891. Allied to *C. picturatum.*

C. stragularium (curtained). *fl.*, middle sepal spotted purple, purple at top, elliptic, cucullate, the lateral ones sulphur, blotched and spotted purple; petals yellowish, spotted purple, brownish-purple at apex; lip numerously spotted with blackish-purple, curved, with two divaricate angles near the base, convolute. *l.* petiolate, cuneate-oblong, blunt, 6in. to 7in. long. 1887. This "may be the same as *C. pulchrum*" (H. G. Reichenbach).

C. Thwaitesii (Thwaites'). *fl.* pale straw-coloured; lateral sepals ½in. long, lanceolate, widely spreading, twice as long as the ovate dorsal one; petals acute. Ceylon (at 4000ft. to 7000ft. elevation). According to Hooker, there is some confusion regarding this species.

C. vaginatum (sheathed). *fl.* pale yellow, 1in. or more in length; dorsal sepal many times longer than the lateral ones; lip two-ridged; scape 2in. to 3in. long, laxly sheathed. *l.* 2in. to 4in. long, oblong, emarginate. Pseudo-bulbs ½in. to 1in. long, conical. Rhizome very stout. Penang, &c., 1843.

C. Wallichii (Wallich's). *fl.* reddish-brown; lateral sepals 1in. to 1½in. long, three or four times as long as the dorsal one; umbels few-flowered; scape equalling or exceeding the leaves. *l.* 2in. to 4in. long, elliptic-oblong. Pseudo-bulbs ¾in. to 1in. long, sub-globose, ovoid or elongated. Temperate Himalaya, 1837. SYN. *C. refractum.*

C. Wendlandianum (Wendland's). *fl.* of a wine-purple colour; sepals ciliated with a few trembling, clavate hairs, and having tails 6in. to 7in. long. British Birma, 1891. Something in the way of *C. Collettii.* (R. X. O., t. 243.)

C. Whiteanum (White's). *fl.* light straw-yellow, with a bright yellow lip. Moluccas (?), 1895. This species is allied to *C. vaginatum,* but has pseudo-bulbs and leaves scarcely half as large.

C. Wightii (Wight's). *fl.* ochreous-green; sepals having a marginal line of red specks, the lateral ones ¾in. long; umbels six- to eight-flowered; scape shorter or longer than the leaf, speckled with red. *l.* 1½in. to 2½in. long, elliptic or linear-oblong. Pseudo-bulbs ovoid. Rhizome stout. Ceylon.

The following species are grown at Kew, but are rarely met with elsewhere: *C. concinnum, C. delitescens, C. mundulum, C. proliferum.*

CISSUS. To the species described on p. 331, Vol. I., the following should now be added. *See also* **Ampelopsis** and **Vitis.**

C. incisa (cut). *fl.* in a somewhat corymbose or compoundly umbellate panicle. *fr.* black, shining, as large as small peas. *l.* thick, pale green, glabrous, the lowest three-lobed, the upper ones trifolioliate; leaflets 1in. to 2in. long, sometimes two- or three-lobed. Stem woody. *h.* 4ft. to 5ft. United States.

C. i. Rocheana (Roche's). *fr.* more globose than in the type. Central Africa. (R. H. 1884, p. 272.)

C. mexicana (Mexican). *fr.* red or white, large, and of a fine flavour. *l.* something like those of the common Vine. Stems annual. Sinaloa, Mexico, 1888.

Cissus—*continued.*

C. velutinus (velvety). *fl.* of an intense coral-red; peduncle at least twice as long as in *C. discolor;* cyme larger and laxer *l.* green, broadly veined with white above, blood-red beneath. Habit as *C. discolor.* Habitat unknown. (B. M. 5207.)

CISTELLA. A synonym of **Geodorum** (which *see*).

CISTUS. Including *Halimium.* About a score species are sufficiently distinct to rank as such: they are all natives of Europe, North Africa, and the Asiatic shore of the Mediterranean.

C. corbariensis. *See* **C. salvifolius corbariensis.**

C. florentinus. *See* **C. monspeliensis florentinus.**

C. guttatus (striped). A synonym of *Helianthemum gutta'um.*

C. tauricus (Taurian). This is one of the varieties of *C. creticus.*

CISTUS, GROUND. *See* **Rhodothamnus Chamæcistus.**

CITRIOBATUS (from *Citros,* a Citron, and *batos,* a thorn; the plant is known in Australia as the Orange Thorn). ORD. *Pittosporeæ.* A small genus (two species) of greenhouse, evergreen, rigid, much-branched, Australian shrubs, with small, solitary flowers, and insignificant, entire or toothed leaves. Both species have been introduced, but they are of little horticultural value.

CITRONELLA. A synonym of **Villaresia** (which *see*).

CITRUS. This genus embraces, according to Hooker, about seven species, natives of tropical Asia and Australia, and several of them broadly cultivated over the tropical regions of the globe. Calyx cup-shaped or urceolate, three- to five-cleft; petals four to eight, linear-oblong, thick, imbricated; stamens twenty to sixty. Fruit globose or oblong, fleshy, many-celled. To the species, &c., described on p. 335, Vol. I., the following varieties should be added:

C. Aurantium Bergamia. Bergamot Orange. *fl.* small, very sweet-scented. *fr.* pale yellow, globose or pear-shaped; pulp acidulous, with a pleasant aroma. (B. M. 7194.)

C. A. Bigaradia. The correct name of *B. vulgaris.*

C. Bergamia. A variety of *C. Aurantium.*

C. Bigaradia. A synonym of *C. vulgaris.*

C. buxifolia (Box-leaved), of gardens. A synonym of *Severinia buxifolia.*

C. Daidai (Daidai). A variety of the Mandarin Orange (*C. nobilis*). 1839.

C. Limetta and **C. Limonum** are varieties of *C. medica.*

C. Lumia (Lumia). Sweet Lemon. *fl.* tinged with red. *fr.* ovoid-oblong, with a long mamilla; rind having convex vesicles. *l.* having a simply-margined petiole. A sub-variety of *C. medica Limetta.*

C. medica Riversii (Rivers'). Bijou Lemon. *fl.* white, small. *fr.* small, globose. *l.* elliptic, serrated, on short, wingless petioles. 1885. (B. M. 6807.)

C. sinensis (Chinese). Chinese Orange. *fl.* very white. *fr.* about as large as a Plum, a little flattened; pulp bitter, acidulous. A variety of *C. Aurantium.*

C. triptera (three-winged). A garden synonym of *C. trifoliata.*

CLADANTHUS (from *klados,* a branch, and *anthos,* a flower; the flowers are produced at the ends of the branches). ORD. *Compositæ.* A monotypic genus. The species, *C. proliferus,* a half-hardy, strong-smelling annual, native of the South of Spain and Northern Africa, has been introduced, but is of no particular horticultural value.

CLADIUM (from *klados,* a twig). ORD. *Cyperaceæ.* A genus embracing about a score species of stove, greenhouse or hardy Sedges, found in all except cold climates. Flowers bisexual; glumes few, concave; spikelets terete, usually panicled or cymose. *C. germanicum* is useful for naturalising in boggy situations.

C. germanicum (German). *fl.*, spikelets ¼in. long, crowded in pedicelled heads ½in. in diameter; cymes axillary and terminal, corymbose, the branches 1in. to 3in. long. July and August. *l.* 2ft. to 4ft. long, ¼in. in diameter, rigid, keeled. Stems 2ft. to 5ft. high, terete or obscurely trigonal. Europe (Britain), North Africa, &c. SYN. *C. Mariscus.*

C. Mariscus (Mariscus). A synonym of *C. germanicum.*

CLADIUS PADI. *See* **Rose Sawflies.**

CLADIUS PYRI is the name scientists have bestowed upon a most destructive species of Sawfly infesting the leaves of both Pear and Plum, and, like many other members of the same family, it is unfortunately double-brooded, appearing in spring and autumn. The perfect insects are on the wing towards the end of April, and the eggs are laid on the under-surfaces of the leaves of the food-plant. They hatch out in rather more than a month, and the young larvæ at once commence to feed upon the leaves. Unlike many Sawflies—that infesting the Cob-nut, for instance—they are seldom observed either when feeding or when at rest, for in the latter condition they remain curled up in the under-sides of the leaves of their food-plant. There is, however, ample evidence of their presence, as the epidermis of the leaves attacked is entirely removed, while a little later large holes are made.

As soon as these larvæ are detected a sheet should be procured, and the branches of the trees lightly tapped, as the insects will fall to the ground on the slightest alarm. Syringing such trees with soapsuds will also make it unpleasant for any that remain, and also cause the insects to drop to the ground, a sheet having been arranged for their reception. From this they may be easily collected and despatched. If allowed to remain, the larvæ, when full-fed, spin a cocoon in the soil, and in that pupate, the perfect insects emerging as before noted. The remedies recommended under **Gooseberry and Currant Sawfly** will also be found useful.

CLADOBIUM. A synonym of **Scaphyglottis** (which *see*).

FIG. 262. FLOWERS OF CLARKIA ELEGANS FLORE-PLENO.

CLADOSPORIUM DENDRITICUM. *See* **Apple and Pear Scab** and **Pear Fungi.**

CLADOSPORIUM FULVUM. *See* **Tomato Leaf-Rust.**

CLADOSTYLES. A synonym of **Evolvulus** (which *see*).

CLAIRISIA. A synonym of **Anredera** (which *see*).

CLANDESTINA. Included under **Lathræa** (which *see*). *C. rectiflora* is now known as *L. Clandestina.*

CLAPPERTONIA. A synonym of **Honckenya** (which *see*).

CLARCKIA. *See* **Clarkia.**

CLARIONEA. A synonym of **Perezia** (which *see*).

CLARKIA. Also spelt *Clarckia.* Including *Phæostoma.* Four species, natives of North America, form this genus. These very effective annuals are very largely employed for borders. Old kinds like *C. elegans* have been improved by the florist, and we now have forms that for effect surpass it easily—Purple King, Salmon Queen, Tom Thumb Rose, and White Queen.

C. elegans flore-pleno. There are some lovely double-flowered forms, white, pink, and violet. They are more ornamental than the singles (see Fig. 262).

CLASS. In botany this term is used for a group of related natural orders.

CLASSIFICATION. *See* **Botany.**

CLAUSENA. *C. Wampi* is the correct name of *Cookia punctata.*

CLAVICEPS PURPUREA. *See* **Ergot Fungus.**

CLAVIFORM. The same as **Clavate** (which *see*).

CLAVIJA. SYNS. *Horta, Zacintha* (of Vellozo). About twenty-five species, all tropical American, are here included. To those described on p. 336, Vol. I., the following should be added :

C. Ernstii (Ernst's). *fl.* pendulous, ¾in. long; corolla fleshy, the disk apricot-colour; racemes 2in. to 4in. long, drooping, many-flowered. July. *l.* clustered at the ends of the branches, on long petioles, coriaceous, 12in. to 16in. long, 4in. to 6in. broad, pale beneath, elliptic-oblong, oblong-lanceolate, or oblanceolate, acute or sub-acute, entire. Trunk (in native specimens) 4ft. to 5ft. high. Caraccas, 1879. (B. M. 6928.)

C. cauliflora (SYN. *Theophrasta antioquensis*) has also been introduced.

CLAY. The bringing of heavy Clay land into a good state of cultivation needs very careful management. The object should be to ridge up the ground in winter as rough as possible, and to expose as great a surface to the action of frost and wind as can be; the addition of strawy-manure, road-scrapings, decayed vegetable matter, burnt refuse, or anything that will render the Clay more porous and friable will be of great service. Burning is a very expensive operation, and it is doubtful whether it would not be more profitable to drain and improve the soil by the addition of other things, than to burn the surface.

CLAY-COLOURED WEEVIL. *See* **Weevils.**

CLAYING. This consists in the addition of Clay to a light, porous soil, to make it heavier and more retentive of moisture, and to improve its staple generally. It is also occasionally used for lining a pond or lake to make it retain water which would otherwise filter away through the bottom and sides. In some parts this is termed "puddling."

CLAYTONIA. About twenty-five species form this genus. To those described on p. 336, Vol. I., the following should be added :

C. alsinoides (Alsine-like). *fl.* white, pedicellate, solitary or racemose; petals having two sharp teeth. March to June. *l.*, radical ones petiolate, ovate, acuminate; upper ones opposite, mucronate. Colombia, 1794. A form of *C. sibirica.* (B. M. 1309.)

CLEARWING MOTHS. *See* **Sesia.**

CLEISOSTOMA. SYN. *Pomatocalpa.* Including *Echioglossum.* This genus comprises, according to the "Index Kewensis," upwards of forty species, mostly natives of the East Indies, the Malayan Archipelago, and tropical Australia. To those described on p. 337, Vol. I., the following should be added:

C. brevipes (short-footed). *fl.* ⅜in. in diameter; sepals and petals orange-yellow, with two purple bands; lip pale yellow; spike 1in. to 1½in. long, dense-flowered. *l.* 4in. long, distichous, uniform, linear-lanceolate, acute, fleshy. Stems tufted, 8in. to 12in. long. Sikkim Himalaya.

C. crassifolium (thick-leaved). *fl.* sea-green, ½in. in diameter, with a rosy lip, produced in nodding panicles from the axils of the leaves. *l.* 8in. to 10in. long, closely set, thick, leathery, much recurved, resembling those of a Vanda. India, 1850. (L. iii., t. 139; L. J. F. 397; P. F. G. iii. 29.)

C. Guibertii (Guibert's). *fl.* pale whitish-yellow, with cinnamon rings; sepals and petals cuneate-oblong, obtuse; lip pandurate; column short; panicle many-flowered. Habitat not recorded, 1862. (L., t. 9.)

C. ringens (gaping). *fl.* ochreous, having the middle lobe of the lip purple and an orange spot on the side lobes; spur very large, broad, cylindrical; raceme few-flowered. *l.* oblong, emarginate, 3in. to 4in. long, 1½in. broad. Philippines, 1888. A pretty little species.

C. Wendlandorum (Wendland's). *fl.* yellow, minute, papillose; raceme or panicle 4in. to 6in. long. *l.* 6in. to 10in. long, 1in. to 1½in. broad, broadly lorate, coriaceous, bilobed. Stems 1in. to 1½in. long, very stout. Tenasserim, &c.

C. Zollingerianum (Zollinger's). A new species, "of Vanda-like habit, but with very short spikes of only a single flower, which is 1in. across and white with red-brown spots" (G. C.). Sunda Islands, 1897.

CLEISTES. Included under **Pogonia** (which *see*).

CLEISTOCACTUS. Included under **Cereus** (which *see*).

CLEITRIA. A synonym of **Venidium** (which *see*).

CLEMATIS. Including *Viorna* and *Viticella.* *Atragene* (*see* Vol. I., p. 143) is also merged hereunder by Bentham and Hooker. About 100 species are included in this genus; they are mostly dispersed over temperate regions, and are rarely found within the tropics. To the species and varieties described on pp. 338-40, Vol. I., the following should be added:

C. Addisoni (Addison's). *fl.*, sepals dark violet-purple, except at the acute, reflexed tips, which are yellow. Alleghany Mountains, 1896. This hardy species is closely allied to *C. Viorna.* (G. & F. 1896, p. 324, f. 43.)

C. alpina (alpine). The correct name of *Atragene alpina.*

C. angustifolia (narrow-leaved). *fl.* yellowish-white, not very numerous, scented, long-pedicellate, disposed in very loose panicles at the tips of the branches; sepals four, truncate, the borders recurved. June and July. *l.*, leaflets four or five, lanceolate, acute, glabrous, long-petiolulate. Austria. Allied to *C. Flammula.*

C. apiifolia (Apium-leaved). *fl.* dull white, with six styles, paniculate. August and September. *l.* ternately cleft; segments ovate, acuminate, incised-toothed. *h.* 10ft. Japan. A strong, hardy climber.

C. barbellata (slightly-bearded). *fl.* dull purple, large; sepals oblong, acuminate, pubescent on both sides, the margins villous; anthers softly bearded on the back; pedicels naked. May. *l.* once ternately divided; leaflets ovate-lanceolate, acute, toothed or lobed. Western Temperate Himalayas. A woody, greenhouse climber. (B. M. 4794.) SYN. *C. nepaulensis.*

C. brevicaudata (short-tailed). *fl.* white, small; peduncles spreading, shorter than the leaves, crowded in panicles. *l.* pinnate; leaflets ovate-lanceolate, acuminate, deeply and sharply serrated, and covered with appressed hairs. China and Japan, 1888. Hardy. SYN. *C. Pieroti.*

C. cærulea. The correct name is *C. patens.*

C. californica (Californian). A variety of *C. ligusticifolia.*

C. coccinea (scarlet). A form of *C. Viorna.*

C. Colensoi (Colenso's). *fl.* greenish-yellow, very sweet-scented, 1½in. across; sepals silky; peduncles and pedicels slender. *l.* generally biternate or trifoliolate with the leaflets three-lobed or tripartite; leaflets ½in. to ¼in. long, ovate-cordate. New Zealand, 1844 and 1889. A slender, greenhouse climber. SYN. *C. hexasepala* (B. R. xxxii., t. 44).

C. connata (connate). *fl.* pale yellow; sepals oblong, subacute, not ribbed, pubescent outside, densely tomentose inside; panicles many-flowered. Autumn. *l.* pinnate; leaflets three to seven, distant, 2in. to 4in. long, broadly ovate-cordate, coarsely serrated or almost three-lobed. Himalayas. A large, woody, hardy climber.

Clematis—*continued.*

C. Davidiana (David's). SYN. *C. mongolica* (of gardens). *See under* **C. tubulosa.**

C. divaricata (divaricate). A synonym of *C. eriostemon.*

C. Douglasii (David Douglas's). *fl.* very deep purple inside, pearl outside, nodding; sepals 1½in. long, oblong, erect, spreading, much longer than the stamens. *l.* hairy, twice or thrice pinnatifid; segments linear, rather obtuse. Stem herbaceous, erect, simple, strongly striated, one-flowered. *h.* 1ft. North America, 1889. Hardy.

C. eriostemon (woolly-stamened). *fl.* bluish-violet; sepals oblong-deltoid, acuminate and revolute at apex, the margins undulated; peduncles three-flowered. Summer. *l.* usually pinnate; segments two or three pairs, thick, dark green, oval, the lateral ones entire, the terminal ones irregularly three-lobed. Tendrils wanting. *h.* 3ft. to 3½ft. Probably North America. (R. H. 1852, p. 341.) SYNS. *C. divaricata* (R. H. 1856, p. 341), *C. Hendersoni* (of gardens).

C. Fremontii (Fremont's). *fl.* purple, terminal, nodding; sepals thick, 1in. long, narrow-lanceolate, recurved at tip. *l.* three or four pairs, simple, coriaceous, sparingly villous, sessile, broadly ovate, 2in. to 4in. long, entire or few-toothed. Stems stout, erect, clustered, 6in. to 12in. high, usually branched. Kansas.

C. fusca (fuscous). *fl.* reddish-brown, campanulate, thickly covered with brownish wool. *fr.* forming a thick, globular head of plumose tails about 1in. across. Stems prostrate or climbing to a height of 6ft. or 8ft. China and Japan. A hardy perennial or under-shrub. SYN. *C. kamtschatica.*

C. graveolens (strongly-scented). A synonym of *C. orientalis.*

C. hakonensis (Hakon). *fl.* violet or violet-purple, spreading, 4½in. to 7in. in diameter; sepals four to six, elliptic or ovate-elliptic, narrowed or rounded and mucronate at apex. July to October. *l.* pinnate; leaflets five to seven, ovate, acuminate, rounded at base, very rarely three-lobed, dark green and glabrous above, villous beneath. Japan, 1860. A vigorous twiner. *C. Jackmanni* (of gardens) is one of the varieties of this species.

C. Hendersoni (Henderson's). A form of *C. reticulata.*

C. Hendersoni, of gardens. A synonym of *C. eriostemon.*

C. heracleæfolia (Heracleum-leaved). *fl.* purplish-blue, somewhat resembling those of a Hyacinth in shape; corymbs borne on short, erect peduncles, which, as well as the branches, are velvety-grey. *l.* pinnatisect; segments ovate-lanceolate, broadly incised-toothed, the ultimate ones three-lobed. *h.* 2ft. China. Hardy. SYN. *C. tubulosa.*

C. h. Hookerii (Hooker's). *fl.* lilac, tubular, ⅜in. long, pedicellate, disposed in axillary clusters. *l.* large, pinnately trifoliolate; leaflets elliptic, acute, dentate. North China, 1885. An ornamental, hardy shrub. (B. M. 6801, under name of *C. tubulosa Hookerii.*) *C. tubulosa* is now regarded as a synonym of *C. heracleæfolia.*

C. hexasepala (six-sepaled). A synonym of *C. Colensoi.*

C. Hookeri (Hooker's). A form of *C. tubulosa.*

C. Jackmanni (Jackmann's). A form of *C. hakonensis.* See p. 340, Vol. I.

C. kamtschatica (Kamtschatkan). A synonym of *C. fusca.*

C. ligusticifolia (Ligusticum-leaved). *fl.* white, fragrant, ⅜in. across, dicœcious, borne in paniculate corymbs. *l.* pinnate and ternate; leaflets oblong, acute, mostly lanceolate-cuneate, incisely toothed and trifid. *h.* 30ft. Rocky Mountains. A somewhat pubescent, hardy, more or less shrubby species.

C. l. californica (Californian). This differs from the type in having smaller, somewhat tomentose leaves. 1840.

C. mongolica (Mongol). A garden synonym of *C. Davidiana.*

C. montana. This is one of the most beautiful of spring-flowering subjects (see Fig. 263), but it requires plenty of space.

C. nepaulensis (Nepaul). A synonym of *C. barbellata.*

C. patens (spreading). The correct name of *C. cærulea.*

C. Pieroti (Pierot's). A synonym of *C. brevicaudata.*

C. Pitcheri. *C. Sargenti* is a form of this species.

C. P. lasiostylis (having a woolly style). *fl.* having the recurved portion of the sepals deep purplish-blue. *fr.* of a richer red and larger than in the type.

C. Pitcheri-coccinea (hybrid). A garden hybrid, intermediate in character between the two parents indicated by the name. 1893.

C. recta flore-pleno (double-flowered). *fl.* greenish-white, double, produced in elegant clusters. 1890.

C. reticulata (reticulated). *fl.* dull greenish and purplish, solitary, pendulous, on long peduncles; sepals connivent, recurved at the tips. September. *l.* leathery, prominently reticulated; upper ones simple, elliptic; lower ones pinnate, with

Clematis—*continued.*

seven to nine variable leaflets. Southern United States, 1880. A rambling, hardy or nearly hardy climber. (B. M. 6574.)

C. r. Hendersoni (Henderson's). *fl.* deep bluish-purple, sweet-scented, over 2in. across; sepals wrinkled. June to September. *h.* 8ft. to 10ft.

FIG. 263. CLEMATIS MONTANA.

C. rhodochlora (reddish-green). *fl.* about the size of those of *C. Viticella*; two smaller sepals vinous-red above, paler towards the base, whitish flushed with red beneath; larger sepals nearly double the size of the smaller ones, green, quite foliaceous. *l.* simple, broadly oval or sub-cordate, shortly stalked. 1887. Garden variety.

FIG. 264. FLOWER AND BUD OF CLEMATIS COUNTESS OF LOVELACE.

C. Robertsiana (Roberts's). *fl.* citron-yellow, nodding, 3in. to 5in. in diameter, terminal, solitary, on long peduncles; sepals four, lanceolate. *l.* on rather long petioles, biternately cut; leaflets ovate-lanceolate, 1in. to 2½in. long, mucronate-serrated. Branches slender, 4ft. to 5ft. long. Afghanistan. A sarmentose, hardy shrub.

Clematis—*continued.*

C. Sargenti (Sargent's). This is merely a small-flowered form of *C. Pitcheri*. North America, 1888.

C. Stanleyi (Lord Derby's). *fl.* rosy-white to purple, 2½in. across, cup-shaped, axillary; sepals spreading, broadly-obovate; peduncles one-flowered, longer than the leaves; panicle leafy. *l.* densely set, bi- or tri-pinnately parted, being cut into slender shreds. South and tropical Africa, 1890. A tall, stout, much-branched, greenhouse shrub, clothed in all parts with pale, silky hairs. (B. M. 7166; G. & F. iii., f. 65; G. C. 1890, viii., p. 326, f. 66; Gn. 1891, p. 789.)

C. stans (erect). *fl.* opal-blue, sub-verticillately clustered, pendulous; whorls disposed in a contracted, terminal panicle; sepals linear, acuminate, recurved. September. *l.* trifoliolate; leaflets obliquely roundish-ovate, acute, deeply toothed or somewhat lobed, wrinkled, the upper ones narrower. Stems erect, herbaceous, softly pubescent. *h.* 2ft. to 3ft. Japan. Hardy. (B. M. 6810.)

C. Suksdorffii (Suksdorff's). This little-known, hardy species of the *Flammula* section "resembles in habit and foliage the widely-distributed and variable *C. ligusticifolia*." North-West United States, 1896. (G. & F. 1896, p. 255, f. 36.)

C. texensis (Texan). A synonym of *C. Viorna coccinea*.

C. verticillaris is the correct name of *Atragene americana*.

C. Viorna coccinea. SYN. *C. texensis.* The garden variety *luteola* has the flowers yellow inside; in *parviflora* they are reddish inside and smaller. 1888. (R. H. 1888, p. 348.)

Varieties. Many new varieties have been added since those enumerated in Vol. I. appeared, but the following selections include the best:

ALBA MAGNA, pure white, with purplish-brown anthers, a lovely variety, free, and hardy; BARILLET DESCHAMPS, large double flowers of a mauve colour, with yellow stamens; BEAUTY OF WORCESTER, bluish-violet, with conspicuous white stamens, very beautiful, hardy, and a continuous blossomer from July to October; BELLE OF WOKING, silvery-grey, large double flowers; COUNTESS OF LOVELACE, bluish-lilac (Fig. 264); DUCHESS OF TECK, pure white, shaded with mauve on first opening; EDOUARD DESPOSSE, deep mauve, with red anthers, large, free, and fine; GLOIRE DE ST. JULIEN, white, flushed with mauve, large, and free; LA FRANCE, deep violet-purple, remarkably free and good; PRINCESS BEATRICE, silvery-lilac, of great size and substance, very fine, June to October; REINE BLANCHE, light mauve, excellent for bedding; SMITH'S SNOW-WHITE JACKMANII, pure white, constant blossomer from July to October.

CLEOME. Bentham and Hooker include *Peritoma* (p. 30, Vol. III.) under this genus. Several species formerly included here are now referred to **Polanisia.**

CLEOPHORA. A synonym of **Latania** (which *see*).

CLERODENDRON. SYN. *Agricolæa.* Including *Cyclonema.* This genus comprises about seventy species, most of them broadly dispersed over the warmer regions of the globe; a few are natives of America (mostly in the West Indies or Colombia), and one is broadly diffused over the maritime regions of tropical America.

The hardy varieties of *Clerodendron* flourish in ordinary garden soil, but the best results are obtained when they are grown in a compost of rough peat and fibrous loam. A sunny spot sheltered from east winds and late spring frosts should be selected. During the growing season, and especially if the soil is naturally dry, copious supplies of water should be given to the plants. *C. trichotomum* may be propagated by division of the roots, the thick, fleshy portions of which should be cut into short lengths and placed in pans of light soil in heat.

To those described on pp. 341-2, Vol. I., the following should be added. They require stove treatment.

C. Balfouri (Balfour's). A variety of *C. Thomsonæ.*

C. cephalanthum (flowers in heads). *fl.* disposed in dense, terminal heads; calyx purplish, large, five-lobed; corolla creamy-

Clerodendron—*continued.*

white, with a narrow tube 3in. to 4in. long and spreading segments; stamens much exserted. *l.* large, ovate, dark green; petioles hardening and forming stout hooks. Stems brown. Zanzibar, 1888. Climber.

C. delectum (chosen). *fl.* showy, freely produced in large, dichotomous cymes; calyx pure white; corolla of a deep, rich magenta-rose. 1885. A handsome garden variety, raised from *C. Thomsonæ Balfouri.*

C. grandiflorum (large-flowered). The correct name of *Ægiphila grandiflora.*

C. illustre (bright). *fl.*, calyx reddish-scarlet, sub-globose; corolla bright scarlet, the tube ¾in. long, the limb eight to nine lines in diameter; panicle branches and pedicels red. *l.* cordate, acute, 7in. to 8in. long, 6in. to 6½in. broad, repand-toothed, glabrous or nearly so above, scaly beneath. Celebes. A showy plant, producing its large panicles of flowers when only 1½ft. high.

C. macrosiphon (long-tubed). *fl.* forming a small, sub-sessile, terminal, reduced cyme; calyx ¼in. long; corolla white, the tube 4in. to 4½in. long, ⅓in. in diameter, hairy, erect, slightly curved; limb one-sided, 1½in. in diameter, five-lobed to the middle. May. *l.* 2in. to 3in. long, oblanceolate or elliptic-lanceolate, acuminate, coarsely and irregularly toothed or almost lobulate, the base gradually narrowed into a petiole. Zanzibar, 1881. A slender, erect shrub. (B. M. 6695.) SYN. *Cyclonema macrosiphon.*

C. Minahassæ (Minahassa). *fl.* yellowish-white, in broad, terminal, cymose panicles; anthers purple, exserted. *fr.* very ornamental, the calyx growing out so as to resemble a red flower 3in. across, with a round, blue berry in the centre. *l.* opposite, obovate, serrated. Stems square. Celebes, 1886. An ornamental shrub.

C. nutans (drooping). *fl.* white, scented, slightly ascending, ternate; calyx reddish-purple; corolla lobes obovate, obtuse, almost equal, flat; stamens longer than the corolla; panicles oblong, loosely pendulous. December. *l.* ternate or opposite, long-acuminate, entire, attenuated at base, very shortly petiolate. *h.* 2ft. to 4ft. Sylhet, &c., 1830. Shrub. (B. M. 3049.)

C. Rumphianum (Rumphius'). *fl.* at first flesh-coloured, deepening to red and crimson, long-tubed, in terminal panicles; stamens red, exserted. *l.* large, roundish-ovate, dark green. Java, 1887. A handsome shrub.

C. scandens (climbing). A synonym of *C. umbellatum.*

C. sinuatum (sinuate). *fl.* shortly pedicellate, disposed in an ample, capitate, compact panicle; corolla pure white, salver-shaped, the slender tube thrice as long as the calyx. February. *l.* petiolate, ovate or ovate-oblong, sub-cordate at base, acuminate at apex, lightly sinuate or angled. Branches copious, tetragonal, slender. *h.* 3ft. Sierra Leone, 1846. A pubescent shrub. (B. M. 4255.)

C. Thomsonæ Balfouri (Balfour's). *fl.* light crimson; calyx rather larger than in the parent. 1885.

C. umbellatum (umbelled). *fl.* few, in a terminal panicle; corolla whitish, reddish at the throat, the tube slender, 1in. long, the limb segments rather large, acute. July. *l.* oval, entire, 3in. long, 1in. broad, coriaceous, petiolate, acute, shining above, yellowish beneath. Stems twining, four-angled, highly glabrous, striated. *h.* 12ft. Western Tropical Africa, 1822. SYN. *C. scandens* (B. M. 4354).

C. viscosum is identical with *C. infortunatum.*

CLETHRA. This genus embraces about twenty-five species, natives of North and South America, Madeira, Japan, and the Malayan Archipelago. Leaves sparse, persistent or rarely deciduous, petiolate, entire, serrated, or toothed. To the species described on p. 342, Vol. I., the following should be added:

C. barbinervis (bearded on the nerves). *fl.* white, in a terminal, elongated, paniculate raceme; rachis, peduncle, and calyx rusty-pubescent *l.* petiolate, obovate or obovate-elliptic, acute, cuneate at base, argutely serrated, glabrous above, the under-surface bristly-pubescent on the primary veins and bearded in the axils of the veins. Japan, 1870. Hardy, deciduous.

C. canescens (hoary). *fl.* white, small, disposed in large, branching panicles, slightly fragrant. *l.* deep green, lanceolate. Java, 1896. A strong-growing shrub.

C. secundiflora (side-flowering). *fl.*, calyx segments obtuse, silky-pubescent; inflorescence side-flowering; pedicels and peduncles tomentose. *l.* oblong-lanceolate, denticulate, entire at base, shortly acuminate, glabrous above, below (as well as the petioles) hairy-pubescent. Habitat not recorded, 1877.

CLETHROPSIS. Included under **Alnus** (which *see*).

CLEYERA. Of the six species included hereunder, two are Indian or Japanese, and the rest are found in Mexico or in the Antilles. To those described on p. 183, Vol. I., the following should be added:

C. Fortunei (Fortune's). *fl.* about ½in. in diameter, solitary or fascicled in the axils or on nodes; calyx lobes reddish-brown;

Cleyera—*continued.*

petals pale yellow. September. *l.* 4in. to 6in. long, elliptic- or linear-lanceolate, bright green, variegated with golden-yellow and scarlet towards the margins. Japan (?), 1861. (B. M. 7434; G. C. 1895, ii., p. 10, f. 1.)

CLIANTHUS. *Donia* (of G. Don) is synonymous with this genus. *C. carneus* is synonymous with *Streblorhiza speciosus.*

CLIDANTHUS. *See* **Chlidanthus.**

CLIDEMIA. SYN. *Staphidium* (for the most part). *C. vittata* is the only species calling for mention here. For culture, *see* **Melastoma.**

C. vittata (striped).* *l.* elliptic, 8in. to 12in. long, 8in. broad, bullate and of an intense green above, with a very distinct silvery central stripe, beneath reddish-tomentose; petioles cylindrical, sulcate above, 2in. long, powdered. Stem and branches terete, robust, softly reddish-tomentose. Peru, 1873. A very ornamental plant. (I. H. n. s., xxii., t. 219.)

CLIFF BRAKE FERN. *See* **Pellæa.**

CLIFTONIA LIGUSTRINA. According to Bentham and Hooker, this is the correct name of *Mylocarium ligustrinum.*

CLIMBING CUCUMBER. *See* **Cyclanthera pedata.**

CLIMBING HYDRANGEA. *See* **Schizophragma hydrangeoides.**

CLINANTHUS. The original spelling of *Clitanthus*, now included under **Stenomesson** (which *see*).

CLINGSTONE. A term applied to Peaches and similar fruits, the flesh of which is not easily separable from the stone.

CLINOSTYLIS. A synonym of **Gloriosa** (which *see*).

CLINTONIA. SYN. *Xeniatrum.* Eight species are included in this genus: two are found on the Himalayas, in Siberia, and in Japan, and the remainder are North American. Flowers in terminal umbels or racemes, rarely solitary; perianth funnel-shaped, deciduous, with six sub-equal segments; stamens six, inserted at the base of the segments. Leaves sub-radical, narrow, ribbed.

C. pulchella (rather pretty). A synonym of *Downingia pulchella.*

CLIOCOCCA TENUIFOLIA. Included under **Linum** (which *see*).

CLIPPING HEDGES. Deciduous Hedges may with advantage be clipped once or twice during the growing season; if this is done with Beech Hedges they retain their foliage all winter, and make an excellent screen. Box Hedges may be clipped in the early autumn or spring. Holly Hedge, Laurels, and similar large-leaved plants should be trimmed with a knife.

CLITANTHUS [originally spelt *Clinanthus.*] Included under **Stenomesson** (which *see*).

CLITORIA. SYN. *Nauchea.* About twenty-seven species, scattered over the warmer parts of the globe, form this genus. Standard spoon-shaped, very large; wings and the incurved keel much shorter.

C. braziliana. The correct name is *Centrosema brasilianum.*

C. Broussonetii (Broussonet's). A synonym of *Cologania Broussonetii.*

C. multiflora (many-flowered). A synonym of *Vilmorinia multiflora.*

C. polyphylla (many-leaved). A synonym of *Barbiera polyphylla.*

C. virginiana (Virginian). A synonym of *Centrosema virginianum.*

CLIVEUCHARIS PULCHRA. A name given by M. E. Rodigas to a hybrid raised in M. Van Houtte's nursery out of a *Clivia* by the pollen of *Eucharis amazonica.*

CLIVIA. *Imantophyllum* is included by modern botanists under this genus, but for horticultural purposes it has been kept distinct in this work. Flowers bright reddish-yellow, scentless, many in an umbel; perianth funnel-shaped, erect or rather curved, the tube short, the

Clivia—*continued.*

segments ascending, sub-equal, obtuse; stamens inserted at the throat. Leaves numerous, distichous, persistent. Bulb imperfect, consisting only of the leaf-bases.

Varieties. ACQUISITION, orange-scarlet; ADMIRATION, a combination of creamy-white and orange-scarlet; AMBROISE VERSCHAFFELT, orange-red; CRUENTA, orange-red; DISTINCTION, orange-red, with white base; FAVOURITE, light orange-yellow, with paler throat; LADY WOLVERTON, orange-yellow; MDLLE. MARIE VAN HOUTTE, orange-scarlet, with deep yellow centre; METEOR, orange-scarlet; OPTIMA, orange-scarlet, banded with yellow, very large flowers; PRESIDENT, bright orange; STANSTEAD BEAUTY, soft orange; SUPERBUM, orange-red.

CLOT BUR. *See* **Xanthium.**

CLOVE. A small bulb, springing from the axils of the scales of a larger bulb; *e.g.*, a Clove of Garlic.

CLOVER, CALVARY. *See* **Medicago Echinus.**

CLUBBING and **CLUB-FOOT.** A disease of Cabbage and other *Cruciferæ* due to one of the so-called "Slime Fungi," *Plasmodiophora brassicæ*. *See* **Finger and Toes.**

CLUB GRASS. *See* **Scirpus.**

CLURAS. Although *C. miniata* is still much grown, yet some of the garden varieties surpass it for general excellence. Some of the best of these are Acquisition, Admiration, Distinction, Favourite, Lady Wolverton, Mdlle. Marie Van Houtte, Optime, President H. Rohan, and Van Houttei. Those who do not want named varieties will find in the seedlings some extremely beautiful kinds.

CLUSIA. About sixty species, all tropical or subtropical American, are included in this genus. Flowers dicœcious or polygamous, borne at the tips of the branches; sepals four to six; petals four to nine. To the species described on p. 344, Vol. I., the following should be added:

C. venosa (veined). *fl.* white or purplish, shortly pedicellate; petals four, about ¾in. long; peduncles three- to five-flowered. *fr.* reddish, berry-like, ovoid, with resinous pulp. *l.* 3in. to 4in. long, rounded or almost truncate at the top, veined on both sides, sub-sessile. *h.* 30ft. West Indies, 1733.

CLUSIACEÆ. Lindley's name for the **Guttiferæ** (which *see*).

CLUSTER. A popular term for bunches of Grapes, Currants, flowers, &c., but having no definite significance.

CLUSTER CUPS. *See* **Æcidium.**

CLUTIA. *See* **Cluytia.**

CLYNHYMENIA. A synonym of **Cryptarrhena** (which *see*).

CLYPEA. A synonym of **Stephania** (which *see*).

CLYTIA is also spelt *Clutia*. SYN. *Altora*.

CNEMIDIA. A synonym of **Tropidia** (which *see*).

CNICUS. Horse Thistle; Plumed Thistle. Most of the species are found in temperate Asia, Europe, North Africa, and America, a few being broadly dispersed. To those described on p. 345, Vol. I., the following should be added. *See also* **Chamæpeuce** (which is included hereunder by Bentham and Hooker).

C. oleraceus (pot-herb). *fl.-heads* whitish or yellowish-white; involucral scales linear-lanceolate, acute, almost unarmed. July. *l.* amplexicaul-cordate, spiny-ciliated, and, as well as the branches and stem, glabrous; lower ones pinnatifid; upper ones ovate, acute. *h.* 3ft. Europe, 1570. SYN. *Cirsium oleraceum*.

C. rhizocephalus (rooting-headed). *fl.-heads* yellowish, stemless. *l.* very spiny, hairy. Caucasus, 1897. SYN. *Cirsium rhizocephalum*.

C. Velenovskyi (Velonovsky's). *fl.-heads* red, beautiful, large, and numerous. *l.* during the first year very much like those of *Chamæpeuce diacantha*. Stems 4½ft. high. 1896. A hardy biennial. SYN. *Cirsium Velenovskyi*.

C. Provosti has also been introduced.

CNICUS (of Gærtner). A synonym of **Carbenia** (which *see*).

CNIDIUM. A synonym of **Selinum** (which *see*).

COAL. When within reasonable distance of the Welsh collieries, Anthracite Coal is probably the most economical fuel to use. It produces great heat with very little attention, is clean, smokeless, and, in addition, burns much longer than ordinary Coals.

COAL-ASHES. For heavy or tenacious soils these, if screened through a fine sieve before applying to the land, are valuable; they also act as gentle fertilisers, as they contain several forms of plant-food. On light land, Coal-Ashes are not advisable, as they would render it still lighter.

COBAMBA. A synonym of **Canscora** (which *see*).

COCCANTHERA. A synonym of **Codonanthe** (which *see*).

COCCINELLIDÆ. *See* **Beetles.**

COCCINIA. According to Bentham and Hooker, this is a synonym of **Cephalandra** (which *see*).

COCCOCYPSELUM [also spelt *Coccocipselum*]. SYNS. *Condalia*, *Lipostoma*. About sixteen species, confined to tropical America, are included in this genus. Berries blue, small, ovoid, two-celled, sometimes two-parted, many-seeded. To the species described on p. 346, Vol. I., the following should be added:

C. buxifolium (Box-leaved). A synonym of *Fernelia buxifolia*.

C. discolor (two-coloured). This species only differs from *C. campanuliflorum* in its fruit, which is a berry of an intense blue, crowned by the calyx. Brazil, 1882.

C. hirsutum (hairy). *fl.* sessile, six to eight in a head; corolla pale violet. *fr.* dark violet, ellipsoid, ⅜in. long, hairy, crowned with the subulate calyx-teeth. *l.* rather long-stalked, roundish-ovate, convex above, tinged with purple beneath. Stems prostrate, at length ascending. Central America, &c., 1860. Plant clothed with spreading hairs. (B. M. 7278.) SYN. *C. repens*, of Morren (B. H. 1866, p. 194, t. xiii., xiv., f. 3 to 5).

C. repens (of Morren). A synonym of *C. hirsutum*.

C. Tontanea (Tontanea). *fl.* white or blue; anthers shortly exserted; heads axillary, pedunculate, three- to five-flowered. *fr.* pretty. *l.* ovate, somewhat acute, hairy-pubescent. Cayenne, &c.

COCCOLOBA. Nearly eighty species of trees or shrubs (sometimes tall-climbing), all American, and mostly tropical, are included in this genus. Flowers shortly pedicellate, spicate-racemose; racemes simple or panicled, terminal or axillary. Leaves alternate, entire. To the species described on p. 346, Vol. I., the following should be added:

C. macrophylla (large-leaved). A synonym of *C. rugosa*.

C. platyclada (flat-branched). A synonym of *Muehlenbeckia platyclada*.

C. rugosa (wrinkled). *fl.* bright red, in a very dense, terminal, sub-sessile, erect raceme, 2ft. or more in length. July. *l.* distant, alternate, 1ft. or more in length, cordate-ovate, sessile, strongly nerved, wrinkled. Stem erect, simple or scarcely divided, 20ft. to 30ft. high, leafy from below to the top. Probably South America. SYN. *C. macrophylla* (B. M. 4536).

COCCOTORUS SCUTELLARIS. *See* **Plum Insect Pests.**

COCCULIDIUM. A synonym of **Cocculus** (which *see*).

COCCULUS. SYNS. *Cebatha*, *Cocculidium*, *Epibaterium*, *Leæba*, *Wendlandia* (of Willdenow). This genus includes about ten species, inhabiting the warmer parts of North America, Africa, and Asia.

COCCUS VITIS. *See* **Vine Scale Insects.**

COCHLEARIA. Includes *Armoracia* and **Ionopsidium** (which *see*), according to Bentham and Hooker.

COCHLIODA (from *kochlion*, a little snail; in reference to the curiously-shaped callus). ORD. *Orchideæ*. A genus embracing about ten species of stove or greenhouse, evergreen, epiphytal Orchids, natives of the Andes. Flowers often red, disposed in loose racemes, pedicellate; sepals equal, spreading, free, or the lateral ones more or less connate; petals nearly similar; claw of the lip erect, the lamina spreading, the lateral lobes round and often reflexed, the middle one narrow, entire or emarginate, not exceeding the sepals; column erect, often slightly incurved; scapes one or two, springing from under the pseudo-bulbs. Leaves oblong or narrow, coriaceous, contracted into the

Cochlioda—*continued.*

petioles. Pseudo-bulbs one- or two-leaved. The species here described should be grown in baskets suspended from the roof of the cool-house. Peat and moss form the most suitable compost; and abundance of water during the growing season is essential. Propagation may be effected by division of the pseudo-bulbs.

C. miniata (scarlet). This is supposed to be a natural hybrid between *C. Noezliana* and *C. vulcanica*. (L. 1897, t. 562.)

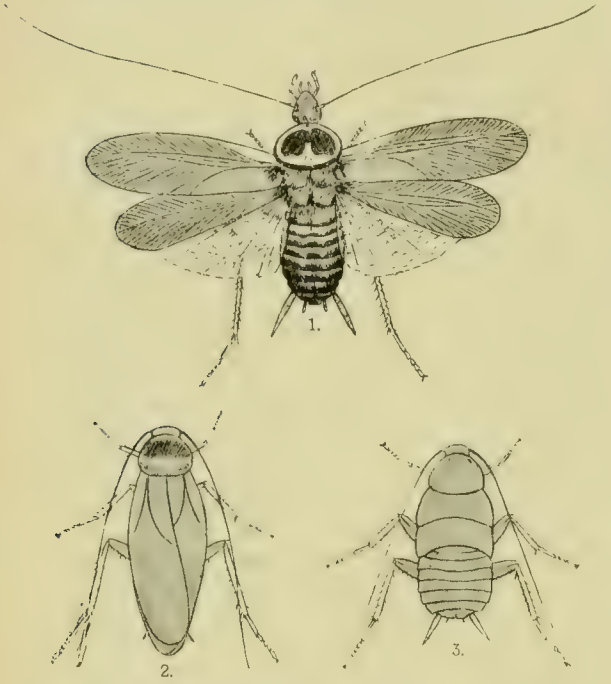

FIG. 265. PERIPLANETA AUSTRALASIÆ. 1, Imago (wings expanded); 2, Imago (wings closed); 3, Immature.

C. Noezliana (John Noezli's). *fl.* orange-scarlet, about 1in. across, with the disk of the lip yellow; lateral sepals narrower and longer than the dorsal one and petals; lip three-lobed, the middle lobe bluntly-obcordate; column triquetrous, dark; peduncles nodding or pendulous, racemose, many-flowered. *l.* linear-oblong, acute, 4in. to 6in. long. Pseudo-bulbs 1½in. to 2in. long, one-leaved. South America, 1891. (L. v., t. 266.) SYN. *Odontoglossum Noezlianum.* There is a form *aurantiaca*, with yellower flowers than in the type. 1896.

C. rosea (rosy). *fl.* wholly rosy-carmine, except the white tip of the column, about 1in. across; sepals and petals oblong-elliptic; lip cuneate at base, the small lateral lobes inclosing the disk, which bears a four-lobed callus, the middle one longer, linear, dilated at the end; racemes drooping, twelve- to twenty-flowered. Winter. *l.* ligulate-oblong. Pseudo-bulbs green, tinted violet, ovate, two-edged. Peru, 1851. SYNS. *Mesospinidium roseum, Odontoglossum roseum* (B. M. 6084; I. H. ser. iii. 66).

C. sanguinea (bloody). *fl.* numerous, bright rose-coloured, waxy in appearance; racemes slender, drooping, slightly branched. Summer and autumn. *l.* two, cuneate-ligulate. Pseudo-bulbs oval, compressed, banded with mottled brown. Peru and Ecuador, 1867. SYN. *Mesospinidium sanguineum* (B. M. 5627).

C. stricta (erect). *fl.* rose-coloured, numerous, erect, smaller than those of *C. rosea* (which they otherwise resemble); peduncle slender, erect. *l.* narrow, acute. Pseudo-bulbs ovate, compressed, bronzy-green. Colombia, 1897.

C. vulcanica (volcanic). *fl.* about 2in. across; sepals and petals dark rose; lip bright rose in front, paler on the disk, where there is a four-keeled callus; the side lobes roundish, the middle one emarginate; racemes unilateral, erect, twelve- to twenty-flowered; peduncle slender, erect. *l* oblong, keeled, 3in. to 5in. long. Pseudo-bulbs ovoid, compressed, more or less two-edged. Eastern Peru, 1872. SYN. *Mesospinidium vulcanicum* (B. M. 6001).

C. v. grandiflora (large-flowered). *fl.* deep rose-coloured, in racemose spikes, larger than in the type. 1893

COCHLOSPERMEÆ. Included under **Bixineæ** (which *see*).

COCHLOSPERMUM. *Azeredia, Maximiliana,* and *Wittelsbachia* are synonymous with this genus.

COCKCHAFERS (*Melolontha vulgaris*). These well-known Beetles seem to be on the increase, or perhaps their depredations are oftener brought home. As stated in Vol. I. they are most undesirable insects in the garden and park; but they are equally objectionable in the orchard and on the farm. As Beetles they feed upon the foliage of nearly all our deciduous shade-trees, as well as upon various fruit trees; while as grubs they are notoriously destructive to grass roots, corn roots, the commoner field crops grown for their roots, nursery beds containing seedlings, and even upon Strawberry-roots. On the Continent, more particularly in France and Germany, the Fir plantations suffer from their ravages, and, with all the insecticides available, man is largely dependent upon the birds and the bats for preserving the requisite balance, especially in the case of grass land.

In addition to the methods for their destruction recorded in Vol. I., gardeners and farmers should try beating the trees in infested districts over tarred boards. This is best done early in the day, when the pests may be found on the under-surfaces of the foliage. They are readily dislodged and should be collected and destroyed.

COCKLE BUR. *See* **Xanthium.**

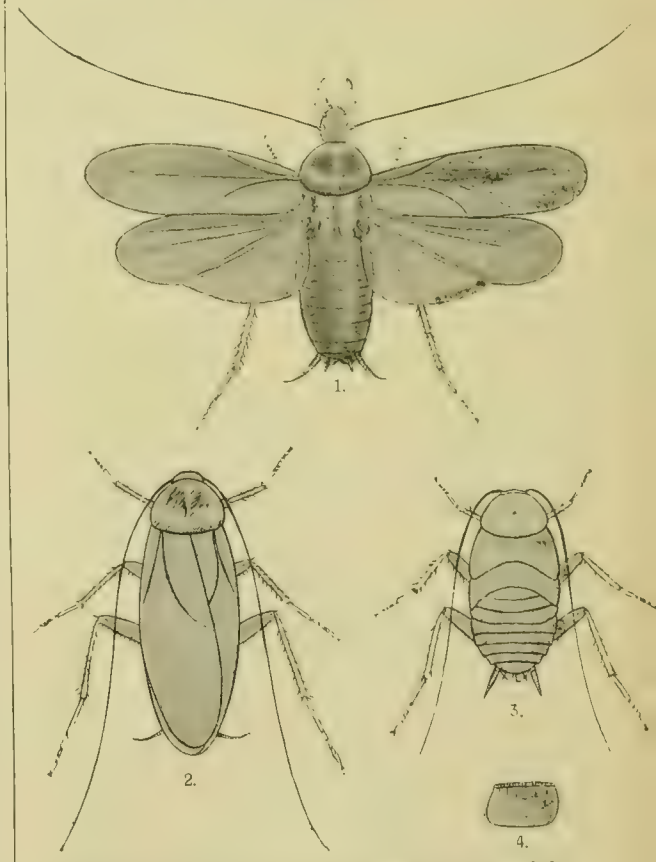

FIG. 266. PERIPLANETA AMERICANA. 1, Imago (wings expanded) 2, Imago (wings closed); 3, Immature; 4, Ootheca (egg-case).

COCKROACHES are Orthopterous insects, doing much damage to fruits under glass, choice flowers (like Orchids), the fronds of Ferns, and many other plants. In vineries they are exceedingly troublesome at times, feeding upon

Cockroaches—*continued.*

the shoots, stems, and footstalks. Twenty years ago the only species that could be characterised as a pest was the Common Cockroach, *Stylophaga* (*Periplaneta*) *orientalis*, which holds its midnight revels in kitchens. More recently, owing to an interchange of commerce, several other species have established themselves in goodly numbers, the heated structures found in gardens generally affording them the necessary warmth. At Kew and many other places where plants are constantly being received from abroad, numbers are taken. In the Palm House and in the forcing-pits at Kew, *P. australasiæ* is reported as doing much damage by attacking young shoots and axillary buds.

The newcomers are: *Periplaneta australasiæ*, already noted (Fig. 265); *P. americana* (Fig. 266); *Phyllodromia germanica* (Fig. 267), the Croton Bug of America;

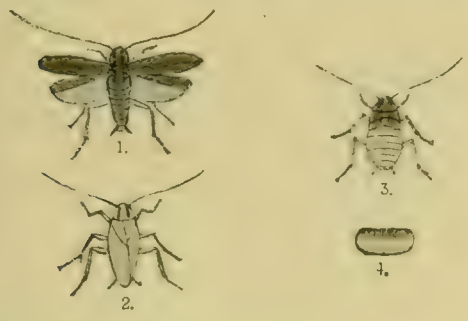

FIG. 267. PHYLLODROMIA GERMANICA. 1, Imago (wings expanded); 2, Imago (wings closed); 3, Immature; 4, Ootheca.

Rhyparobia (*Panchlora*) *maderæ* (Fig. 268); and *Leucophæa surinamensis* (Fig. 269). The first three are the commonest, the last two being but occasionally met with. First as to

Cockroaches—*continued.*

Cockroaches generally take a long time to arrive at maturity—five years, but *P. germanica* is an exception, arriving at maturity in about nine months. They are very difficult to exterminate once they have established themselves, so well are their ootheca (egg-cases) protected.

In addition to the insecticides mentioned in Vol. I., Snow's Magic Paste may be named. We have found this very effective.

FIG. 269. LEUCOPHÆA SURINAMENSIS (showing mature and immature insect).

COCKSCOMB. This name is applied to *Erythrina Crista-galli* and *Rhinanthus Crista-galli*, as well as to the genus *Celosia*.

COCKSPUR FLOWER. *See* **Plectranthus.**

COCKSPUR, WEST INDIAN. *See* **Pisonia aculeata.**

COCKTAIL BEETLES. *See* **Staphylinidæ.**

COCOA PLANT. *See* **Theobroma Cacao.**

COCOA ROOTS. A common name for the roots of *Caladium bicolor* and some other species of that genus.

COCO DE MER. *See* **Lodoicea.**

COCOS. Including *Glaziova*. Upwards of thirty species have been described, natives of tropical and sub-tropical America. Spadices erect, at length drooping; lower spathe

FIG. 268. RHYPAROBIA (PANCHLORA) MADERÆ (showing insect with expanded and unexpanded wings).

P. australasiæ: This is larger than *S. orientalis*, and has perfect wings in both sexes, whereas our kitchen pest is only winged in the case of the males. In colour it is a red-brown, with a yellow streak along the costal margin of the fore-wing at the basal half; the *pronotum* is almost black, but has a yellow margin. *P. americana* is also fully winged (see Fig. 266), and is minus the yellow markings found upon *P. australasiæ*; it is also larger. *P. germanica* is the smallest of the Cockroaches named above, being only about half the size of *S. orientalis*. It is variable as to colour, but usually some shade of light brown, and is winged in both sexes. So far, *P. germanica* has not invaded our plant-houses to the extent of the other two species; but inasmuch as Cockroaches generally are practically omnivorous, they must all be regarded as undesirable visitors.

the shorter, cleft at apex, the upper one fusiform or clavate, woody, sulcate at back. To the species described on pp. 348-9, Vol. I., the following should be added. *See also* **Syagrus** (which is included by botanists under *Cocos*) and **Acrocomia.**

C. Blumenavi (Blumenhaav's). A synonym of *C. eriospatha.*

C. butyracea (buttery). *fl.*, spadices as long as the spathe; branchlets simple, thickly clustered, 1ft. long, deflexed; spathe cylindrical-oblong, attenuated at both ends, 4ft. to 6ft. long. *l.* pinnate; pinnæ simple. Colombia, 1850. Plant unarmed.

C. capitata (headed). *fl.*, spadix long-pedunculate, the branches 4in. to 5in. long; spathe narrow-fusiform, 1½ft. to 2ft. long, sulcate. *l.* spreading, 6ft. or more in length, forming a dense head; pinnæ straight, sub-erect, complicate, linear, acuminate, rigid, glaucous beneath. Caudex thick, 10ft. to 12ft. high. Minas Geraes.

Cocos—*continued.*

C. Datil (native name). *fl.*, spadix 4ft. or more in length, with as many as 300 branches, and borne on a peduncle 16in. long; spathe incurved, beaked. *l.* 12ft. to 16ft. long; pinnæ linear, acuminate; sheath about 16in. long. Caudex tall, 4in. to 12in. in diameter, naked, narrowly-annulate. Argentine, 1889.

C. criospatha (woolly-spathed). *fl.*, spadix thick, contracted; rachis 8in. to 10in. long; branches sixty to ninety; spathe thick and woody above, ending in a long point, pale fuscous within, softly fuscous-woolly outside. *l.* longer than in *C. capitata*, pectinate, glaucescent; lower segments 1½ft. to 2ft. long, elongated, linear, very long-acuminate, the upper ones narrow-linear, all rigid. Caudex dwarf or tall. Brazil, 1889. SYN. *C. Blumenavi.*

FIG. 270. COCOS WEDDELIANA.

C. flexuosa (bending). *fl.*, spadix 1½ft. to 2ft. long, long-pedunculate; spathe 1½ft. long, woody, glabrous, deeply sulcate, fusiform, shortly beaked. *l.* somewhat crisped, about 6ft. long, lightly arcuate-spreading; segments seventy to ninety on each side, linear, acuminate-cuspidate, densely aggregated in twos or threes, the central ones 10in. to 14in. long. Caudex usually tall, rarely dwarf, flexuous, squamate with the persistent bases of the two-edged petioles. Brazil.

C. graminifolia (Grass-leaved). *fl.*, spadix 20in. to 28in. long; lower spathe very short, the upper one very narrow, fusiform, obtusely beaked; peduncle long, slender, compressed. *l.* slender, erecto-arcuate, crisped, 3ft. long; segments thirty to forty on each side, 8in. to 10in. long, about ¼in. broad, acuminate. Plant almost stemless. Brazil.

C. leiospatha (smooth-spathed). *fl.*, spadix 1½ft. or less in length, slender; spathe slightly woody, smooth on both surfaces.

Cocos—*continued.*

l. glaucous, 3ft. long, shortly petiolate; segments equidistant, linear, acuminate. Caudex dwarf, thick, naked below, with a densely-congested mass of persistent petioles towards the top. Brazil.

C. Marie Rose. A garden name for *C. Procopiana.*

C. Normanbyi (Normanby's). A synonym of *Ptychosperma Normanbyi.*

C. odorata (scented). *fl.*, spathe cylindrical, elongated, apiculate. *fr.* drupe-like, sub-globular, yellowish-green or pink, pulpy, scented. *l.* arched; leaflets in threes or fives, linear-lanceolate, conduplicate, acute, coriaceous, glaucescent beneath; petioles spiny. Stem short. South America, before 1893. (R. H. 1893, p. 346, *f.* 110.)

C. oleracea (pot-herb). *fl.*, spadix 1½ft. to 2ft. long, at first erect, then spreading or nodding; spathe 1½ft. to 2ft. long, longitudinally sulcate, tomentose outside when young. *l.* dense, 6ft. to 8ft. long; pinnæ linear, somewhat falcate, acute, obliquely adnate, slightly crisped, glaucous beneath. Caudex 60ft. to 80ft. high. Brazil, 1846. The buds are used economically by the natives.

C. petræa (rock-loving). *fl.*, spadix variable in size, usually about 1ft. long, the rachis simple or very rarely divided into two or three branches; lower spathe shortly two-winged, the upper one woody, fusiform-rostrate. *l.* few, slender, 1½ft. to 3ft. or more in length, shortly petiolate; segments aggregated in twos or threes, solitary towards the apex, linear, acuminate. Plant usually almost stemless. Brazil, Bolivia, &c., 1889.

C. Procopiana (Marianna Procopio Ferriera's). *fl.*, spadix 16in. long; spathe thickened, woody, narrow-fusiform. *l.* fifteen to twenty crowded in a dense head; segments usually in threes or fours, crisped, spreading, the lower ones 2ft. long and scarcely ⅛in. broad, the upper ones shortened. Caudex about 15ft. high. Brazil. SYN. *C. Marie Rose* (of gardens).

C. Pynaerti (Pynaert's). A seedling variety of *C. Weddeliana.*

C. Weddeliana Pynaerti (Pynaert's). *l.* gracefully arched; pinnules rather broader and more closely placed than in the species, which is shown in Fig. 270.

C. Yatay (native name). *fl.*, spadices 4½ft. long, drooping; lower spathe 2ft. long, coriaceous, the upper one 4½ft. long, longitudinally dehiscent above the middle. *l.* much crowded, 6ft. to 10ft. long, revolute-spreading, long-sheathing; segments fifty to sixty on each side, at length equidistant, linear, acuminate, the middle ones 3ft. long and ¼in. broad, the uppermost ones filiform; petioles spiny-serrated. Caudex 12ft. to 15ft. high and more than 1ft. in diameter, densely squamate with the petiole-bases above. Brazil.

The following species have also been introduced, but are at present very rare in cultivation: *C. Bonneti, C. insignis, C. odorata, C. Yurumaguas.*

CODAMBA. A synonym of **Canscora** (which *see*).

CODAZZIA. A synonym of **Delostoma** (which *see*).

CODIÆUM. According to the authors of the "Genera Plantarum," the number of distinct species is only four, and they are found in the South Pacific Islands, Australia, and the Malayan Archipelago. The garden varieties, however, are very numerous. To those described on pp. 350-5, Vol. I., the following should be added:

C. appendiculatum (having an appendage). *l.* having a terminal lobe borne on a filiform production of the midrib. Polynesia, 1875.

C. aureo-lineatum (golden-lined). *l.* green, with the exception of the margins and a line from the midrib, which are yellow. Fiji, 1878.

C. aureo-marmoratum (gold-marbled). *l.* 1ft. long, 3in. broad, dark olive-green, marbled with yellow. 1884.

C. aureo-punctatum (gold-dotted). *l.* linear, obtuse, bright green, dotted and spotted with yellow. 1883. A small form.

C. Austinianum (Austin's). *l.* erect, 6in. to 9in. long, 2in. broad, blotched and margined with creamy-white and suffused with pink, the margins undulated. 1883. A compact form, of dwarf, branching habit.

C. Beauty. *l.* lanceolate, green, variegated golden-yellow, the ground-colour eventually becoming a deep bronze, while the yellow variegations change into a rich rosy-crimson. South Pacific, 1887.

C. Bismarcki (Bismarck's) *l.* of a deep green, veined and blotched with yellow. Polynesia, 1876.

C. Bragæanum (José Terceiro Da Silva Braga's). *l.* pendulous, linear-lanceolate, 1½ft. to 1¾ft. long; many of the young ones pale yellow, marbled and mottled light green; others green, spotted golden-yellow; mature ones deep olive-green, spotted and speckled bright yellow, the midribs crimson. 1882.

Codiæum—*continued.*

C. Broomfieldii (Broomfield's). *l.* 9in. to 10in. long, 2in. to 2½in. wide, dark green, lined, spotted, blotched, and margined yellow, and having a central band of the same colour; midrib tinted red. 1887.

C. Bruce Findlay. *l.* large, oblong-ovate, freely variegated with yellow on the lines of the midrib and principal veins. 1882. A bold and handsome plant.

C. caudatum-tortile (twisted-tailed). *l.* pendulous, twisted, some of them deep olive-green, with a yellow central band and a crimson midrib; others almost wholly yellow, becoming suffused with crimson; others variously blotched and spotted. 1883. A graceful form.

C. contortum (twisted). *l.* ovate, acuminate, recurved, 6in. to 8in. long, having the cross-veins and margins sulphur-yellow on an olive-green ground. 1884. This plant resembles *C. volutum.*

C. cornigerum (horn-bearing). *l.* banded with orange-yellow. Polynesia, 1873.

C. Crœsus. *l.* oblong-lanceolate, bright green, blotched with yellow. 1883.

C. cronstadtii (Kronstadt). *l.* of medium size, lanceolate, twisted, curled, and crisped, tapering to a sharp point, deep, glossy green, variegated with light golden-yellow. 1882. An interesting plant.

C. Dayspring. *l.* oblong-elliptic, orange-yellow, edged dark green, the yellow parts becoming tinged with red on the older leaves. 1882.

C. Delight. *l.* oblong, acute, 6in. to 8in. long, 1¼in. to 2in. broad, when young bright yellow, margined green, the midrib and primary veins creamy, the central variegation changing with maturity to clear ivory-white, a few dots of the same colour being scattered along the margin. Antipodes, 1888.

C. eminens (eminent). *l.* broadly lanceolate, tapering, glossy green, the midrib and part of the lateral veins white. 1883. Habit dense.

C. excurrens (excurrent). *l.* oblong, stalked; midrib excurrent like a small horn near the apex of the leaf, which is variegated with greenish-yellow. 1884.

C. Exquisite. *l.* 6in. to 9in. long, 2in. broad, obovate, acuminate, arching, pale green, marbled and margined primrose and yellow.

C. Eyrei (Eyre's). *l.* long and narrow, twisted, recurved, freely variegated with yellow; petioles and young branches red. 1883.

C. formosum (handsome). *l.* green, spotted yellow, which afterwards changes to crimson; centre and principal veins yellow, becoming, with the margin, a bright magenta-purple; leafstalks crimson.

C. Goednoughtii (Goednought's). *l.* clear green, variegated with yellow. Santa Cruz, 1876.

C. Golden Queen. *l.* 8in. to 10in. long, 3in. broad, ovate, acuminate, deep green, spotted with gold, the centre wholly golden; petioles rose-colour.

C. heroicum (heroic). *l.* green, freely marked deep yellow, the veins, and often the half, or even the whole, leaf-surface, being yellow, occasionally flushed or lined rosy-crimson.

C. Jubilee. *l.* 10in. to 14in. long, 2in. broad, lanceolate, acuminate, with a broad, central stripe, cross veins, and a narrow margin of golden-yellow, which colour changes with maturity to a fiery-crimson. 1887.

C. Junius. *l.* long, narrow, varying in outline, the lower half lemon-yellow, becoming suffused crimson with age, the remaining portion bronzy-green; petioles and stems bright orange-scarlet. 1888.

C. Katharina. *l.* 9in. to 12in. long, 2in. broad, spiral, closely set, splashed and marbled crimson and scarlet. 1887.

C. lineare (linear). *l.* 4in. to 6in. long, linear, usually obtuse, but sometimes narrowed to the point, dark green, with a yellow midrib and a few lateral blotches of the same colour, occasionally almost wholly yellow.

C. Magnificent. *l.* ovate-lanceolate, 6in. to 8in. long, 2½in. broad, when young having a central variegation of golden-yellow; with maturity the margins become deep olive-green, while the midrib and primary veins, with a narrow band on each side the midrib, assume a bright carmine. 1888.

C. Monarch. *l.* oblong, acute, 1ft. long, 2½in. broad, dark green, spotted bright yellow. Antipodes, 1888.

C. Mrs. Swan. *l.* 6in. to 9in. long, 1½in. broad, lanceolate, acuminate, arching, the centre irregularly marked with golden-yellow, the margin of dark green spotted with golden-yellow; petioles and stem crimson.

C. musaicum (mosaic). *l.* oblong lanceolate, acuminate, wavy, crimson, with one or two series of irregular, green blotches on each side of the midrib; in the young leaves the crimson is replaced by a creamy colour, affording a very handsome variegation. 1883. SYN. *Croton musaicus* (R. H. 1882, 240).

C. Nestor. *l.* lanceolate, bright green, variegated with yellow and whitish, the variegation forming a broad, central stripe, the midrib bright magenta-crimson. Polynesia, 1887. A form of *C. medium variegatum.* See Fig. 271.

Codiæum—*continued.*

C. ornatum (adorned). *l.* green, blotched yellow, and with a narrow central band and long parallel veins of creamy-yellow, the yellow parts becoming crimson; occasionally the lines and blotches are rosy-pink, and the midrib is of a deep rosy-crimson

C. Phillipsii (Phillips'). *l.* linear-lanceolate, 8in. to 10in. long, ¾in. broad, the base rich golden-yellow, this colour extending half-way through, and continuing along the centre nearly the whole length. 1886.

C. picturatum (painted). *l.* blotched with red and yellow. New Hebrides, 1876.

C. Prince Henry. *l.* 1ft. to 1¼ft. long, 3in. broad, recurved, the midrib crimson and gold, furrowed, with a narrow margin, occasionally spotted on a dark, bronzy-green ground; markings changing with maturity to a deep blood-red.

C. Princess of Waldeck. *l.* broadly lanceolate, about 4in. long, the central portion of a bright, clear yellow, with a broad and distinct margin of deep green. 1882. A handsome variety.

C. recurvatum (recurved). *l.* recurved, lanceolate, acuminate, marked with yellow along the crimson midrib and lateral veins. 1883.

C. reginæ (Queen's). *l.* olive-green, with orange, yellow, and crimson markings. Polynesia, 1878.

C. ruberrimum (very red). This is one of the narrow, drooping-leaved forms, with the usual crimson and creamy variegation. 1884.

C. rubro-lineatum (red-lined). *l.* spreading, oblong-lanceolate, 1in. to 1½in. long, when first expanded pale yellow and green, many of them tinged rose, but deepening with age to golden-yellow or olive-green, the midrib and nerves, and in many cases the margin also, becoming crimson. 1882. A fine plant.

C. Russelli (Russell's). A seedling form of *C. pictum.* 1893. (J. H. xxvii., p. 493, f. 71, under the name of *Croton Russelli.*)

C. Sceptre. *l.* ribbon-like, dark bottle-green, spotted with fiery orange and yellow; midrib crimson. 1884.

FIG. 271. UPPER PORTION OF BRANCH OF CODIÆUM NESTOR.

C. Sunshine. *l.* 9in. to 10in. long, about 2in. wide, dark bronzy-green, when young blotched with yellow, which gradually changes into rosy-crimson, eventually becoming blood-red. South Sea Islands, 1887.

C. Thomsoni (Thomson's). One of the many seedling forms of *C. pictum.* 1893.

C. torquatum (chain-bearing). *l.* green, with yellow spots that change to red, broken up into chain-like segments. Polynesia, 1878.

C. Torrigianianum (Marchesi Torrigiani's). *l.* plain, about 1in. broad, at first ribbed and veined with yellow, subsequently assuming a high crimson tint along the midrib, margins, and transverse arching veins, the intermediate spaces being green; petioles and stem red. 1884. A handsome plant, in the way of *Queen Victoria.*

C. Van Oosterzeei (Van Oosterzee's). *l.* narrow-linear-lanceolate, acuminate, green, spotted with yellow. 1883. A small but distinct and ornamental shrub. (I. H. 1883, 502.)

C. Victory. *l.* 1ft. long, 2½in. broad, deep olive-green, with crimson veins and midrib, from which latter extends, in an arcuate manner, a coloration of reddish-crimson, the deep green between the primary veins being broken up in an irregular manner by the same bright colour; young ones orange-yellow, suffused crimson. 1888.

Codiæum—*continued.*

C. vittatum (striped). *l.* green, marked with a broad band of creamy-yellow, which runs out laterally along the bases of the distant primary veins; petiole (as well as the midrib in older leaves) bright ruby-red. 1887.

C. Wigmannii (Wigmann's). *l.* 8in. to 10in. long, ¼in. broad, irregular in form, rich green, blotched with yellow. 1886. A good decorative plant for the table.

CODLIN MOTH. *See* **Apple** or **Codlin Grub.**

CODONANTHE (from *kodon*, a bell, and *anthos*, a flower; in allusion to the shape of the corolla). SYNS. *Coccanthera*, *Hypocyrta* (in part). ORD. *Gesneraceæ*. A small genus (five species) of stove, herbaceous plants, found creeping or climbing over rocks and trees in Brazil and Guiana. Flowers whitish, solitary in the axils, shortly pedicellate; calyx free, with five linear segments; corolla tube declinate or decurved, the throat rather broad, the limb oblique, with five spreading lobes. Leaves opposite, entire, often rather small and slightly fleshy. For culture of *C. gracilis*, the only species introduced, *see* **Gesnera.**

C. gracilis (slender). *fl.* creamy-white, spotted with orange on the under-side of the tube within; peduncles short, red, single or in pairs, one-flowered. June. *l.* opposite, thick, fleshy, ovate, dark green above, pale and often blotched with red beneath. Stem branched, terete, purplish-brown, rooting from below the insertion of the leaves. Organ Mountains, 1850. SYN. *Hypocyrta gracilis* (B. M. 4531).

CODONIUM. A synonym of **Schœpfia** (which *see*).

CODONOPHORA. A synonym of **Paliavana** (which *see*).

CODONOPSIS. This genus includes about a dozen species, natives of the Himalayas, Yunan, Mandschuria, and Japan. To those described on p. 356, Vol. I., the following should be added:

C. clematidea is probably only a form of *C. ovata.*

C. lanceolata (lanceolate). *fl.* forming a short, simple raceme; corolla pale lilac outside, violet inside, the segments ovate-deltoid. *l.* on the stems alternate, those on the branchlets approximating, shortly petiolate, oblong-lanceolate, 1in. to 2in. long, entire or remotely crenulate. Stems twining, 2ft. to 3ft. long, purplish. China (cultivated in Japan), 1861. Tuberous-rooted. SYN. *Campanumœa lanceolata* (F. d. S. 927).

C. ovata (ovate). *fl.* pale blue; corolla broadly campanulate, 1in. to 1½in. long; peduncles 3in. to 6in. long, terminal. *l.* ovate, ¼in. to ⅜in. long, alternate and opposite, obtuse or acute, hairy on both surfaces; petioles ¼in. to ⅜in. long. Stems 6in. to 12in. long, decumbent, then erect. Himalayas, 1856. Half-hardy perennial. (G. C. 1856, p. 468.)

CŒLANTHA. A synonym of **Gentiana** (which *see*).

CŒLEBOGYNE. Included under **Alchornea** (which *see*).

CŒLIA. SYN. *Bothriochilus.* Of this genus there are about half-a-dozen species, natives of the West Indies, Central America, and Mexico. To those described on p. 356, Vol. I., the following should be added:

C. bella (beautiful). *fl.* three or four, erect, 2in. long; perianth yellowish-white, with rose-purple tips to the segments, and having an orange mid-lobe to the lip, tubular below, funnel-shaped above; scape 2in. to 4in. long, clothed with brown sheaths. Autumn to December. *l.* several, 6in. to 10in. long, elongate-ensiform, acuminate. Pseudo-bulbs 1½in. to 2in. long, globose or ovoid. Ile St. Catherine, 1832. (B. M. 6628; W. O. A. ii. 51.) SYNS. *Bifrenaria bella* (L. J. F. iii., 325), *Bothriochilus bellus.*

C. Mooreana, a garden form, is also in cultivation.

CŒLIOPSIS. *C. hyacinthosma* thrives under cool-house treatment.

CŒLOGLOSSUM. Included under **Habenaria** (which *see*).

CŒLOGYNE. SYNS. *Acanthoglossum*, *Chelonanthera* (in part). This genus embraces about fifty species, broadly dispersed over the East Indies and the Malayan Archipelago, one extending as far as South China.

The majority of the dwarf-growing section of Cœlogynes are best grown in pots or pans. The taller and more robust-growing varieties, such as *C. Dayana*, *C. Massangeana*, *C. tomentosa*, and the more recently introduced *C. Veitchii*, with its charming pendulous spikes of pure white flowers, are certainly better accommodated in baskets, which may be suspended near the roof-glass. The

Cœlogyne—*continued.*

plants under these conditions are brought nearer the light, which greatly assists them in maturing their growths, and thus induces them to flower more freely. Moreover, when the flowers are expanded, the baskets are more easily removed to positions in which to display their racemes of flower to the best advantage. The usual mixture of peat and sphagnum is the best potting material.

C. pandurata does best when placed on a block or teak raft, arranged horizontally on the stages, or suspended from the roof. A small quantity of fibrous peat and living sphagnum should be packed carefully and firmly around the base of the plant, to retain the desirable moisture at the roots. It requires a hot, humid atmosphere at all seasons of the year.

To those described on pp. 356-8, Vol. I., the following should be added:

C. Balfouriana (Balfour's). *fl.* coloured cinnabar, orange, and white, disposed in long, arched spikes. 1896. Described as a free-flowering and distinct species, but habitat not recorded.

C. birmanica (Birma). *fl.* having a shortly-toothed front border to the lip, and a nearly entire border round the anther; along the crests are several brown spots on a white ground. Birma, 1883. Probably only a trifling variety of *C. præcox.*

C. borneensis (Bornean). *fl.* small; sepals and petals whitish; lip marked with reddish-brown; raceme about 5in. long. *l.* obovate. Pseudo-bulbs ovoid, two-leaved. Borneo, 1893.

C. carinata (keeled). *fl.*, sepals and petals whitish-green, 1in. long; lip spotted with brown, three-lobed; scape 4in. to 8in. long, six-flowered. *l.* oblong-lanceolate, 5in. long. Pseudo-bulbs four-angled, 2in. long, two-leaved. New Guinea, 1895.

C. Clarkii (Clark's). *fl.*, sepals and petals light brown; lip of a yellowish-brown, margined with brown. Habitat not recorded, 1893.

C. concolor (one-coloured). *fl.*, sepals and petals dark rose; lip dark rose, with yellow blotches, in which are several brownish-crimson spots, elegantly fringed, the crest pale yellow. *l.* (and pseudo-bulbs) as in *C. præcox.* India. SYN. *Pleione concolor*

C. coronaria (crowned). A synonym of *Trichosma suavis.*

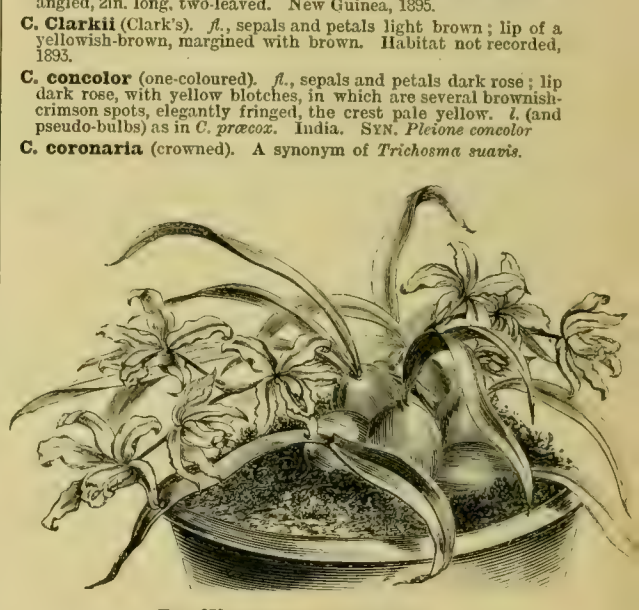

FIG. 272. CŒLOGYNE CRISTATA.

C. cristata. The habit of this beautiful and easily-grown species is shown in Fig. 272.

C. c. alba (white). *fl.* wholly white. Winter and spring. India. (L., t. 173; W. O. A. ii. 54.) SYN. *C. c. hololeuca.* See Fig. 273.

C. c. citrina (citron-colour). *fl.* having the centre of the lip stained delicate lemon-colour. Nepaul. SYN. *C. c. Lemoniana.*

C. c. hololeuca (wholly white). A synonym of *C. c. alba.*

C. c. Lemoniana (Lemon's). A synonym of *C. c. citrina.*

C. c. major (larger). *fl.* larger than in the type, with much broader and stouter sepals and petals. India.

C. c. maxima (greatest). A large-flowered variety, with unusually broad sepals and petals, and shallow side lobes to the lip. 1886.

C. cuprea (coppery). *fl.* somewhat resembling those of *C. speciosa*, but reduced in size, drooping; stalks bearing five to eight bracts. *l.* oblong. Pseudo-bulbs long, Onion-like. 1892.

C. Dayana (Day's). *fl.* light ochreous; sepals and petals ligulate, acute; lip broad, three-lobed, the side lobes striped dark brown, wavy, the middle lobe reniform, crenulate, with a dark brown

Cœlogyne—*continued.*

crescent, two keels running from the base of the lip to the base of the middle lobe, where they divide into six; inflorescence long, lax, many-flowered. *l.* stalked, oblong, acuminate. Pseudo-bulbs long, narrow, fusiform. Borneo, 1884. (G. C. n. s., xxvi., p. 44; W. O. A. vi. 247.)

C. elata (tall).* *fl.* medium-sized; sepals and petals white, narrowish; lip white, with a forked, yellow band in the centre, and two orange-striped crests on the disk; racemes erect, springing with the leaves from the apex of the pseudo-bulbs. *l.* sword-shaped, striated. Pseudo-bulbs tall, oblong, angled. Tongoo, Darjeeling (8000ft. to 9000ft.), 1837. (B. M. 5001.)

C. elegans (elegant). A synonym of *C. Huettneriana.*

C. fimbriata (fringed). *fl.*, sepals yellowish-green or brownish, ovate-lanceolate, ¾in. long; petals filiform; lip yellow, streaked with reddish-brown, the mid-lobe fringed, scape 1in. to 2in. long, one-flowered. October and November. *l.* sessile, 2in. to 5in. long, lanceolate. Pseudo-bulbs ovoid-oblong, ¾in. to 1½in. long. Khasia and China. (B. R. 868.)

C. flavida (yellowish). *fl.* yellow, ½in. across, sub-erect; scape slender, eight- to ten-flowered. Spring. *l.* 3in. to 6in. long, petiolate, narrow-lanceolate, acuminate. Pseudo-bulbs 1in. to 2in. long, distant, on a slender, scaly rhizome. Sikkim Himalaya, &c., 1838.

FIG. 273. CŒLOGYNE CRISTATA ALBA.

C. flexuosa (flexuous). *fl.* white, with a slight yellow stain across the middle of the lip, extended as a narrow line on either side of the disk to near the base, at which point the lip is very sharply constricted, producing a narrow, transverse channel underneath. Java, 1892.

C. Foërstermanni (Foërstermann's.) *fl.* white, with some yellowish-brown on the disk of the lip; sepals and petals ligulate, acute; lip trifid, the lateral laciniæ rounded, the middle one rounded and apiculate; peduncles sometimes forty-flowered. *l.* cartilaginous, ribbed, 1½ft. long, 3in. or more wide, on very short petioles. Sunda Islands, 1887.

C. fuliginosa (sooty). *fl.* expanding one at a time, 2in. across; sepals and petals brownish-white, with a rosy tinge; lip similarly coloured, the mid-lobe deep reddish-brown; racemes shorter than the leaves, two- or three-flowered. *l.* broadly lanceolate, 5in. to 7in. long. Pseudo-bulbs 2in. to 3in. long. Northern India, 1838. (B. M. 4440; L. J. F., t. 7.)

C. glandulosa (glandular). *fl.* pure white, 1¼in. in diameter, disposed in a nodding raceme; front lobe of the lip ovate, marked on the disk with yellow lines. *l.* oblong-lanceolate. Pseudo-bulbs ovate, sulcate. Nilghiri Mountains, 1882.

C. graminifolia (Grass-leaved).* *fl.* nearly 2in. across the petals; sepals white, narrowly oblong-lanceolate, acute; petals similar, but rather narrower; lip three-lobed, the lateral lobes white, streaked purple, oblong, the middle one orange-yellow, with three purple ridges; raceme two- to four-flowered; scape 1in. to 2in. long. January. *l.* two, Grass-like, 1ft. to 1½ft. long. Pseudo-bulbs 1in. to 1½in. long. Moulmein, 1883. (B. M. 7006.)

C. Hookeriana brachyglossa (short-lipped). *fl.*, lip white, with light sulphur on the disk, and with several reddish-brown spots, open, not at all abruptly convolute, yet the upright sides of the lip show lobes. 1887.

Cœlogyne—*continued.*

C. Huettneriana (Huettner's). *fl.* white, eight to ten in a raceme; lip toothed, with a rounded-ovate mid-lobe; bracts 1in. long, cymbiform; scape 7in. long. *l.* petiolate, oblong-lanceolate. Pseudo-bulbs fusiform, much wrinkled. Tenasserim. SYN. *C. elegans.*

C. humilis albata (white-clothed). In this variety the sepals and petals are snowy-white, and the lip is white, with light mauve-purple, radiating lines of small, confluent spots, and with an orange spot on each side of the anterior part.

C. javanica (Javanese). *fl.* yellowish-green, with a white lip and column; lip fringed and bearded; column petaloid; scape one-flowered, with leafless membranous sheaths often piercing the dead leaves. Pseudo-bulbs spherical. *h.* 2in. to 4in. Java.

C. lactea (milky). *fl.*, sepals and petals creamy-white, faintly tinged yellow; side laciniæ of lip light ochre, veined brown, mid-laciniæ bright yellow at base. *l.* 7in. to 8in. long, very thick, cuneate-oblong, acute, petiolate. Pseudo-bulbs light green, plump, short, wrinkled. Birma, 1883.

C. lamellata (lamellate). *fl.*, whitish-green; sepals and petals oblong-lanceolate, keeled, 1¼in. long; lip three-lobed, corrugated; scape erect, three-flowered. New Hebrides, 1895.

C. lentiginosa (freckled). *fl.* 1¼in. in diameter; sepals and petals pale green or straw-coloured; side-lobes of lip margined with brown, the large mid-lobe white with orange blotches; broadly clawed; raceme (including the scape) 4in. to 5in. long, sheathed up to the flowers, which number five to eight. *l.* linear-oblong, 6in. to 8in. long. Pseudo-bulbs 3in. to 4in. long, obtusely four-angled. Tenasserim, 1847. (B. M. 5958.)

C. Lowii (Low's). A synonym of *C. asperata.*

C. lurida (lurid). *fl.*, sepals and petals greenish-yellow, tinged with purple; lip white and purplish, three-lobed. Origin not recorded. 1896. (L. 1896, t. 532.)

C. maculata alba (white). A variety having white flowers. 1893.

C. m. Arthuriana (Arthur Veitch's). *fl.* smaller than in the type, having purple lines on the petals, and a continuous purple band around the front margin of the lip. 1881.

C. m. virginea (virgin-white). *fl.*, lip tinted with light sulphur, the nearly evanescent, purple lines in the middle very few. 1887.

FIG. 274. CŒLOGYNE MASSANGEANA.

C. Massangeana. A flower of this fine Malayan species is shown in Fig. 274.

C. Mayeriana (Mayer's). *fl.* having green sepals and petals, and a green and black lip, resembling those of *C pandurata.* Tropical Asia, 1894.

C. Micholitzii (Micholitz's). A provisional name for what is described as a new introduction from "the East." In habit it resembles *C. barbata*, and is said to have "scapes 2ft. high, bearing large, pure white flowers." 1895.

C. Mossiæ (Mrs. Moss's). *fl.* pure white, 1¼in. across, with a yellow, crescent-shaped mark on the lip; raceme 6in. long, about six-flowered. *l.* 6in. long. Pseudo-bulbs 1¼in. long, ovate, two-leaved. Nilghiri Mountains, 1894. Allied to *C. nervosa.* (G. C. 1894, xv., p. 400, f. 49.)

C. nervosa (nerved). *fl.*, sepals and petals white, acute, the former 1in. to 1¼in. long; lip white and yellowish-brown; bracts very large; scape erect, sheathed up to the few flowers. *l.* oblong-lanceolate, 4in. to 6in. long. Pseudo-bulbs, 2in. to 3in. long, ovoid, curved. Nilghiri Mountains.

C. ochracea (ochreous). *fl.* white, very fragrant, produced in erect racemes of about seven or eight; lip having two horseshoe-shaped blotches on the disk, which are bright ochreous-yellow, bordered orange. *l.* two or three, lanceolate. Pseudo-bulbs small, oblong. North-east India, 1844. (B. M. 4661; B. R. 1846, 69; L. J. F. 342.)

Cœlogyne—*continued.*

C. peltastes (half-moon-like). *fl.* resembling those of *C. pandurata*, except in the lip, which is creamy-white with yellowish-brown markings. Pseudo-bulbs crescent-shaped, rather wide and flat, concave, forming receptacles for water. Borneo, 1880. (L. vi., t. 258.)

C. præcox (early). The correct name of the plant described on p. 358, Vol. I., as *C. Wallichiana.*

C. p. tenera (slender). *fl.* pale lilac and yellow, having a few purple-mauve blotches on the lip. 1883.

C. prolifera (proliferous). *fl.* greenish-yellow, small; scape long, slender, many-flowered. *l.* 3in. to 7in. long, petiolate, lanceolate. Pseudo-bulbs 1½in. to 2½in. long, distant, ovoid or oblong, compressed. Tropical Himalayas, 1837.

C. pulchella (rather pretty). *fl.* pure white, with the exception of a brown blotch on the disk of the lip and a smaller one at the base; scapes terminal, slender, bearing several flowers. *l.* rather thick, oblong-lanceolate. Pseudo-bulbs ovoid-oblong, two-leaved. 1898.

C. purpurascens (purplish). *fl.* nearly white, small; scape 3in. to 4in. long, one- to three-flowered. *l.* 1in. to 4in. long, ½in. to ½in. broad, coriaceous, often purplish. Pseudo-bulbs very slender, one-leaved. Ceylon.

C. rigida (rigid). *fl.* yellow, with three red ridges on the disk of the lip; sepals ½in. long; scape (with the drooping raceme) 6in. to 8in. long, rigid. *l.* petiolate, elliptic-lanceolate, 4in. to 6in. long. Pseudo-bulbs 3in. to 5in. long, narrow-oblong. Tenasserim, 1837

C. Rochusseni (Rochussen's). *fl.* pedicellate, pendulous; sepals keeled, acuminate; petals smaller; raceme very long, flexuous. *l.* elliptic, lanceolate, or oblong-lanceolate. Pseudo-bulbs ovate or oblong, angled, two-leaved. Java.

C. Rossiana (Ross's). *fl.*, sepals and petals creamy-white, ligulate, acute; lip mostly ochre, the disk, broad claw, and top of the mid-lacinia white; column white, with a brown mid-line in front; bracts linear, acuminate. *l.* two, long-petiolate, cuneate-oblong-lanceolate, acute, more than 1ft. long and 1½in. broad. Pseudo-bulbs 2in. to 3in. long, nearly obpyriform. Birma, 1884. (B. M. 7172.)

C. Rumphii (Rumphius'). *fl.* disposed in a spike 6in. long; sepals and petals apple-green, the former lanceolate, the latter linear; lip pandurate, the side lobes spotted with red, the middle one pure white. *l.* 1ft. long, obovate. Pseudo-bulbs oblong. Amboyna, re-introduced 1896.

C. salmonicolor (salmon-coloured). *fl.* salmon-coloured, solitary, the three-lobed lip being somewhat tessellated with brown. *l.* solitary, cuneate-oblong, acuminate, undulated, green at base, coppery elsewhere. Pseudo-bulbs tetragonal, pear-shaped. Java or Sumatra, 1883. Allied to *C. speciosa*, but smaller.

C. Sanderæ (Mrs. Sander's). *fl.* white, 2in. across, with a yellow blotch on the lip and a fringe of long, brown hairs on the three parallel keels; scapes erect. *l.* ovate-lanceolate. Pseudo-bulbs ovate, tapering, 3in. to 4in. long. Upper Birma, 1893. Allied to *C. barbata.* (G. C. 1893, xiii., pp. 336, 360, f. 52; J. H. 1893, xxvi., p. 313, f. 59; R. t. 56.)

C. Sanderiana (Sander's).* *fl.* snow-white, large and showy; sepals ligulate, acute; petals lanceolate, acute, dilated above; side laciniæ of the lip marked with three brown stripes, the anterior lacinia yellow, with a few white marks, and having yellow crests; peduncles sometimes nine-flowered. *l.* petiolate, cuneate-oblong, acute, chartaceous. Pseudo-bulbs fusiform-cylindrical, two-leaved. Sunda Isles, 1887.

C. sparsa (sparse). *fl.* white; lip three-lobed, having a brown spot in front of the keels, some smaller ones on the side lobes, and a yellow one at the base; peduncle one- to four-flowered. *l.* cuneate-oblong, acute, glaucous, 3in. to 4in. long, 1in. broad. Pseudo-bulbs glaucous, fusiform. Philippines, 1883. A charming, dwarf plant.

C. stellaris (star-like). *fl.*, sepals and petals green; lip white, marked with brown lines on the side lobes. Pseudo-bulbs tetragonal. Borneo, 1886.

C. Swaniana (J. M. Swan's). *fl.* 2in. across; sepals white, 1in. long; petals white, narrower; lip pale brown, darker round the margins and tips of the lobes; column yellow; raceme 1ft. long, many-flowered. May and June. *l.* two, 6in. to 8in. long, elliptic-lanceolate; petioles 2in. to 3in. long. Pseudo-bulbs 3½in. to 4in. long, obtusely four- to six-angled. Philippine Islands, 1892. (B. M. 7602; R., ser. ii., t. 92.)

C. tenuis (slender). *fl.* of a light buff tint, small. Borneo, 1893. This species is allied to *C. borneënsis*, but differs in having slender scapes, one-leaved pseudo-bulbs, &c.

C. testacea (brick-coloured). *fl.* 1½in. across; sepals and petals pale brown; side lobes of lip dark brown, margined with white, narrow, the mid-lobe broad; column white; raceme many-flowered, pendulous. *l.* 6in. to 8in. long, lanceolate, petiolate. Pseudo-bulbs 3in. to 5in. long, narrow-ovoid. Singapore, 1842.

C. thuniana (Thunia-like). A synonym of *C. uniflora.*

C. tomentosa (downy). *fl.* 2in. to 2½in. in diameter; sepals and petals light orange-red; lip white, streaked with red on the inner side, obovate in outline, the mid-lobe three-keeled; racemes pendulous, the rachis and pedicels roughly tomentose. *l.* 9in. to 12in. long, variable. Pseudo-bulbs elongated-ovoid, 2in. to 3in. long. Borneo, 1873.

C. uniflora (one-flowered). *fl.* white or flesh-coloured; sepals 1in. long; lip having three to seven orange spots; scape ½in. to 1in. long, one- or two-flowered. *l.* 3in. to 6in. long, erect, narrow-lanceolate. Pseudo-bulbs 1in. to 2in. long, ovoid, crowded. India. (R. X. O. i., t. 46.) SYN. *C. thuniana.*

C. Veitchii (Veitch's). *fl.* pure white, about 1in. in diameter; racemes drooping, 2ft. long, many-flowered. *l.* lanceolate, 6in. long. Pseudo-bulbs fusiform, 4in. long. New Guinea, 1895.

C. ventricosa (big-bellied). A synonym of *Pholidota ventricosa.*

C. virginalis (virgin-white). A provisional name for an imported plant described as having pure white flowers in the way of *C. cristata*, and deliciously fragrant. Habitat not recorded, 1896.

The following are also in cultivation at Kew: *C. asperata sumatrana*, *C. conferta*, and *C. Lauterbachiana.*

CŒLOSTYLIS. A synonym of **Spigelia** (which *see*).

COETANEOUS. Contemporary; of the same age.

COFFEA. About a score species, natives of tropical Asia and Africa and the Mascarene Islands, form this genus. Flowers white. Fruit globose or oblong, dry or fleshy, two-stoned. To the species described on p. 358, Vol. I., the following should be added:

C. arabica (Arabian). This is partly synonymous with *C. liberica*, and partly with *C. stenophylla.*

C. stenophylla (narrow-leaved). *fl.* ⅓in. long, one to three together, sub-sessile, in axillary clusters. *fr.* ½in. long, black when ripe. *l.* elliptic-oblong or obovate, caudate-acuminate, 1½in. to 5½in. long; petioles very short. Stem about 10ft. high, 13in. in diameter near the base. Upper Guinea, 1896. "One of the two indigenous West African species, which, in point of commercial value, may prove a formidable rival to the Arabian." (B. M. 7475.)

COHORT. In botany, this term is used for a group of natural orders within a class. *See* **Class.**

COIX. SYN. *Lithagrostis.* Three or four species are included in this genus. Spikelets unisexual, monœcious, spicate, the upper ones mostly males, the females one or two at the base of the spike; glumes four.

COKE. An excellent fuel for nearly all kinds of hot-water boilers, and in the neighbourhood of gasworks may be cheaply purchased. Probably it is next to Anthracite for heating, economy, and cleanliness, being practically smokeless, and requiring little attention.

COLA. Kola Nut-tree. SYNS. *Lunanea*, *Siphoniopsis.* Half-a-dozen tropical African species compose this genus. Flowers fascicled in the axils, shortly cymose, or sub-paniculate; calyx usually five-cleft; petals wanting. Leaves entire or lobed.

COLAX HARRISONIÆ. A synonym of **Bifrenaria Harrisoniæ** (which *see*).

COLCHICUM. About thirty species, natives of Europe, West and Central Asia, and North Africa, are here included. To those described on p. 359, Vol. I., the following should be added:

C. agrippinum (Wild Olive-like). *fl.*, two to four to a spathe; perianth tube whitish, 2in. to 4in. long, the limb of a beautiful lilac-purple tessellated with white, 1½in. to 2½in. long. Autumn. *l.* three or four, vernal, sub-erect, lanceolate, 6in. to 9in. long. Corm ovoid, 1in. to 1½in. thick. Origin unknown. An old favourite in English gardens. SYN. *C. tessellatum.*

C. alpinum parvulum (rather small). *fl.* pale lilac, smaller, and leaves narrower than in the type. Italy, &c., 1834.

C. Bornmülleri (Bornmüller's). This closely resembles *C. speciosum*, of which it is perhaps merely a geographical form. May. Orient, 1892.

C. byzantinum cilicicum (Cilician). *fl.* as large as those of *C. speciosum.* Asia Minor, 1896. A handsome variety.

C. candidum (white). A synonym of *C. lætum.*

C. caucasicum (Caucasian). A synonym of *Merendera caucasica.*

C. cilicicum (Cilician). A form of *C. byzantinum.*

C. crociflorum (Crocus-flowered) (B. M. 2673.) A synonym of *C. autumnale.*

C. Decaisnei (Decaisne's). *fl.* pale rosy-purple, large; perianth tube much longer than the elongated, elliptic segments (which are 1½in. to 2in. long); stamens rather shorter than the perianth.

Colchicum—*continued.*

l. 6in. to 8in. long, 1in. to 1½in. broad, lanceolate, attenuated above. Orient, 1892.

C. fasciculare (fascicled). *fl.* white, numerous, fascicled; perianth tube two-and-a-half times longer than the limb, the segments nearly 1½in. long, narrow-elliptic-lanceolate. February. *l.* five to seven, lanceolate, 6in. long, six to ten lines broad. Syria, &c., 1896. According to J. G. Baker, this is merely a form of *C. montanum.*

C. lætum (pleasing). *fl.* often pale lilac (or white, flushed with pale rose), many to a spathe; perianth tube 2in. to 6in. long, the limb 2in. to 2½in. long, the segments ½in. to ¾in. broad. Autumn. *l.* four to six, lingulate, sub-erect, sometimes 1ft. long and 1in. to 2in. broad. Leafy stem at length 5in. to 6in. long. Corm 1½in. to 2in. thick. Tauria, 1897. SYN. *C. candidum.*

C. latifolium (broad-leaved). A synonym of *C. Sibthorpii.*

C. montanum (of Linnæus). A synonym of *Merendera Bulbocodium.*

C. montanum Ritchii (Ritch's). *fl.* pink or rarely white; filaments crested at base. Asia Minor, 1897.

C. Parkinsoni is a form of *C. variegatum.*

C. parvulum (rather small). A form of *C. alpinum.*

C. procurrens (running). *fl.* one to a spathe; perianth tube pale, 4in. long, the segments bright lilac, 1in. long. Autumn. *l.* appearing in spring, three to a sheath, linear, ½in. broad, dull glaucous-green. Smyrna. SYN. *Merendera sobolifera* (of gardens).

C. Ritchii (Ritch's). A form of *C. montanum.*

C. Sibthorpii (Sibthorp's). *fl.* three or four in a spathe, tessellated with lilac-purple; perianth tube often 6in. long, the limb 1½in. to 2in. long. Autumn. *l.* four or five, broadly strap-shaped, appearing in spring. Corm 1½in. to 2in. thick. Greece and Armenia, 1890. SYN. *C. latifolium.*

C. tessellatum (tessellated). A synonym of *C. agrippinum.*

C. Troodii (Trood's). *fl.* numerous; perianth white, 1½in. in diameter, the segments narrow-oblong. Autumn. *l.* appearing in spring, 6in. to 12in. long, ⅜in. to 1in. broad, strap-shaped, obtuse, dark green. Corm depressed-globose. Cyprus, 1886. (B. M. 6901.)

COLEA. Nine or ten species, natives of the Mascarene Islands, are included in this genus. To those described on p. 360, Vol. I., the following should be added:

C. mauritiana (Mauritian). *fl.* dark rose, shortly pedicellate, fascicled on the stems; corolla glabrous. *l.* oblong, warted. *l.*, leaflets in whorls of three, almost sessile, elliptic-lanceolate, acuminate. Mauritius.

COLEBROOKIA. Sir J. D. Hooker regards this as a monotypic genus, *C. ternifolia* not being specifically distinct from *C. oppositifolia.*

COLENSOA (named in honour of the Rev. W. Colenso, who assisted Hooker in the investigation of the botany of New Zealand). ORD. *Campanulaceæ.* A monotypic genus. The species is a glabrous, erect herb, suffrutescent at base. It will thrive in sandy loam, and would probably succeed in the open air, in a warm, sheltered place. Propagated by seeds or by cuttings.

C. physaloides (Physalis-like). *fl.* very pale bluish, 1½in. long, bilabiate, the upper lip divided into two linear lobes; stamens free of the corolla tube, the filaments scarcely connate; racemes short, terminal, leafless, few-flowered. Summer. *fr.* a violet, globose berry, crowned by the linear, green calyx teeth. *l.* alternate, petiolate, elliptic-ovate, acute, doubly serrated, 4in. to 6in. long. *h.* 2ft. to 3ft. New Zealand, 1886. (B. M. 6864.)

COLEOPHORA HEMEROBIELLA. *See* **Pear Insects.**

COLEOPHYLLUM. A synonym of **Chlidanthus** (which *see*).

COLEOSPADIX (from *koleos*, a sheath, and *spadix*; in allusion to the inflorescence). ORD. *Palmæ.* A monotypic genus. The species, *C. oninensis*, is in the Kew Collection, but is not in general cultivation.

COLEOSPORIUM. Included under **Peridermium** (which *see*).

COLEUS. About fifty species are included in this genus, natives of tropical Asia, Africa, and (one) Australia. It differs from *Plectanthus* only in the filaments being combined below into a sheath around the style. To the

Coleus—*continued.*

species and varieties described on p. 361, Vol. I., the following (all perennials) should be added:

C. Gibsonii (Gibson's). An ornamental plant, having the leaves blotched and veined with purplish-crimson. Native country uncertain, 1866. (F. M., t. 338.)

C. Penzigii (Penzig's). *fl.*, lower lip bright violet, ¼in. long, the upper one smaller, reflexed; whorls simple, eight-flowered, forming a lax raceme 6in. to 8in. long. Autumn. *l.* ovate, 2in. to 3in. long, crenate, pubescent, narrowed suddenly to a winged petiole. Stems clothed with spreading hairs. Mountains of Abyssinia (?), 1893. Perennial.

C. spicatus (spiked). *fl.* ¼in. long; whorls in a dense, cylindric, spike-like, villous thyrse, 8in. long. *l.* sub-sessile, obovate, ovate, or orbicular, 3¼in. long, glabrous, fleshy, entire or crenate. Stem very stout, villous or glabrate, 6in. to 12in. high, simple or branched. South Deccan. Perhaps the typical species is not in cultivation.

C. s. Rondinella (Rondinella). *fl.* blue, disposed in racemes. *l.* fleshy. *h.* 8in. Abyssinia, 1896. A bushy herbaceous plant. (R. G. 1896, p. 358, f. 62.)

C. thyrsoideus (thyrsoid). *fl.* blue, shortly pedicellate; corolla about ¼in. long, the mouth bilabiate; raceme about 3in. broad, the branchlets sub-erect or spreading. February. *l.*, lower ones 7in. long, ovate-cordate, acuminate, coarsely lobulate and crenate; petioles 2in. or more in length; upper leaves smaller, with more deeply-cleft margins. Stem, petioles, and inflorescence pubescent. *h.* 2ft. to 3ft. British Central Africa, 1897. (B. M. 7672.)

COLIC ROOT. *See* **Aletris farinosa.**

COLLABIUM (from *collum*, a neck, and *labium*, a lip; in allusion to the basal part of the lip encircling the column). ORD. *Orchideæ.* A small genus (two species) of stove, terrestrial Orchids, natives of India, Java, and Borneo. Flowers in a long raceme on a tall scape; lateral sepals adnate to the trumpet-shaped foot of the long, incurved column, to which the short lip is also jointed; pollinia two. Leaf plicate. *C. simplex* is the better known species. *C. nebulosum* is in the Kew Collection. For culture *see* **Catasetum.**

C. simplex (undivided). *fl.*, sepals and petals greenish-yellow, with purple and brown blotches; lip white; column white, purple at base; peduncle tumid at base, racemose at apex. *l.* oblong, acute, wavy, green, with darker blotches. Borneo, 1881.

COLLADONIA (of Sprengel). A synonym of **Palicourea** (which *see*).

COLLÆA. Included under **Galactia** (which *see*).

COLLANIA (of Herbert). Included under **Bomarea** (which *see*).

COLLANIA (of Schultes). A synonym of **Urceolina** (which *see*), the correct name of *C. urceolata* being *U. pendula.*

COLLAR. The line of junction between a stem and a root.

COLLATERAL. Side by side.

COLLEMBOLA, or SPRINGTAILS. These are minute insects belonging to the *Aptera*, and are often found in damp spots in the garden. Two out of the three families into which the Sub-Order *Collembola* is divided are capable of leaping; but the remaining one, *Lipuridæ*, does not possess the power of doing so. Like *Aptera* generally, these insects feed upon both animal and vegetable refuse; they cannot be regarded as destructive. Species of *Lipuridæ* are sometimes found in Mushroom-houses, and may be found working up in minute heaps between the bricks, when these are employed.

COLLETOTRICHUM LINDEMUTHIANUM. *See* **Bean Anthracnose.**

COLLYRIS. A synonym of **Dischidia** (which *see*).

COLOCASIA. The five species of this genus are indigenous to tropical America, one being cultivated in all warm regions. To those described on pp. 362-3, Vol. I., the following should be added:

C. Devansayana (Devansaye's). *l.* ample, erect, peltate, ovate, acute, cordate-sagittate at base, highly glabrous, green, the sinus large, triangular; primary veins three or four on both sides, produced on the lower surface, brown; petioles elongated, terete, sheathing at base, coppery-brown. Caudex short and thick. New Guinea, 1886. (I. H. 1886, 601.)

C. esculenta and **C. nymphæifolia** are varieties of *C. antiquorum.*

C. odorata. The correct name is *Alocasia odora.*

COLOCYNTH. *See* **Citrullus Colocynthis.**

COLOPHONIA. A synonym of **Canarium** (which *see*).

COLORADO BEETLE. *See* **Potato Beetle,** Vol. III.

COLPOON-TREE. *See* **Elæodendron.**

COLQUHOUNIA. Three or four species, all natives of India, compose this genus. To the information given on p. 363, Vol. I., the following should be added:

C. tomentosa (R. H. 1873, p. 131) is synonymous with *C. coccinea.*

C. vestita (clothed). According to Sir J. D. Hooker, this is merely a woolly variety of *C. coccinea.*

COLUMBINE, FEATHERED or **TUFTED.** *See* **Thalictrum aquilegifolium.**

COLURIA. *Laxmannia* (of Fischer) is identical with this monotypic genus.

COLUTEA. Eight or ten species have been described, but probably not more than half of them are distinct as such; they are found in Central and Southern Europe and in temperate and sub-tropical Asia. To those described on p. 364, Vol. I., the following should be added. *See also* **Sutherlandia** and **Swainsona.**

C. arborescens melanocalyx (dark-calyxed). A variety having the calyx and pedicles clothed with dark hairs. Asia Minor, 1892.

C. frutescens (shrubby). A synonym of *Sutherlandia frutescens.*

C. longialata (long-winged). This species, which is probably a native of Asia Minor or the Balkan Peninsula, is closely related to *C. arborescens.* 1896.

COLVILLEA (named in honour of Sir Charles Colville, Governor of the Mauritius). ORD. *Leguminosæ.* A monotypic genus. This species is a stove, unarmed tree, thriving in any fairly good compost. Propagation is effected by cuttings, inserted in sand, under a bell-glass, in heat; or by seeds when these are to be had.

C. racemosa (racemose). *fl.* bright scarlet, showy, much crowded; racemes axillary and terminal, 1½ft. long, simple or branched. April and May. *l.* alternate, remote, spreading, oblong-ovate, 3ft. long, bipinnate, the lower ones reflexed; pinnæ twenty to thirty pairs, opposite, 4in. long, with twenty to twenty-eight pairs of linear leaflets ½in. long. *h.* 40ft. to 50ft. Mauritius. (B. M. 3325-6.)

COMANTHOSPHACE. ORD. *Labiatæ.* A genus embracing four species of greenhouse or hardy undershrubs, natives of Japan. *C. japonica* (B. M. 7463), a small plant with hoary branches and inflorescence, is grown at Kew, but is of no particular horticultural value.

COMAROUNA ODORATA. A synonym of **Dipteryx odorata** (which *see*).

COMARUM. This genus is included by Bentham and Hooker under **Potentilla** (which *see*), the correct name of *C. palustre* being *P. Comarum.*

COMATOGLOSSUM. A synonym of **Talisia** (which *see*).

COMB FERN. *See* **Schizæa.**

COMBRETUM. *Poivrea* should be included here, according to Bentham and Hooker. The genus embraces about 120 species, common in tropical America, Africa, and Asia, and in South Africa, but not in Australia or Polynesia.

C. coccineum (scarlet). The correct name of *Poivrea coccinea.*

C. comosum (crowded). *fl.* of a beautiful intense scarlet, crowded on the elongated spikes, which form a compound panicle; bracts lanceolate. May to August. *l.* opposite, oblong, acute, entire, glabrous when adult, sub-cordate at base, shortly petiolate. Branchlets pubescent. *h.* 20ft. Sierra Leone, 1822. (B. R. 1165.) SYN. *Poivrea intermedia.*

C. nanum (dwarf). *fl.* white; petals narrow-obovate, far exceeding the sepals; raceme often sub-terminal and solitary, 6in. to 7in. long; peduncle 1in. to 2in. long. *l.* opposite or alternate, typically 4in. by 3½in., but often smaller and narrower, varying from round-obovate to lanceolate, glabrous. Branches 6in. to 18in. long. India, 1825. Plant decumbent.

COMMELINA. SYNS. *Ananthopus, Erxlebia, Hedwigia.* About ninety species of this genus have been described; they are all tropical or sub-tropical. Flowers blue, yellowish, or rarely white, rather small, in usually bifid cymes, emerging one at a time from a terminal, complicate or funnel-shaped or cucullate spathe, those of the upper branch of the cyme small, deciduous, those of the lower fertile; sepals three, membranous, the two inner often connate at base; petals longer, one larger and often clawed; stamens three perfect and two or three imperfect. Leaves ovate, lanceolate, or linear. To the species described on p. 365, Vol. I., the following should be added:

C. nudiflora (naked-flowered). *fl.* of a showy cobalt-blue. Argentina, 1897. A compact-growing species. SYN. *C. Sellowiana.*

C. pallida (pale). *fl.* blue; spathes oblong, acuminate, folded in two, pubescent. *l.* almost petiolate, oblong, acute, pubescent on both sides; sheaths violaceous, ciliated. Stem erect, branched, pubescent. Mexico. SYN. *C. rubens.*

C. rubens (reddish). A synonym of *C. pallida.*

C. Sellowiana (Sellow's). A synonym of *C. nudiflora.*

C. tuberosa (tuberous). *fl.* sky-blue; spathes ovate-cordate, long-acuminate, corduplicate, ciliated. June and July. *l.* oblong-lanceolate, acute; sheaths pubescent and ciliated. Roots tuberous. Mexico, 1732. Half-hardy perennial.

COMMERSONIA (named in honour of Philibert Commerson, who died in 1727). ORD. *Sterculiaceæ.* A genus embracing about eight species of stove trees or shrubs, natives of tropical Asia and Australia, and closely allied to *Rulingia. C. platyphylla* (B. M. 1813) has been introduced, but is probably not now cultivated.

COMMIA. A synonym of **Excœcaria** (which *see*).

COMMIANTHUS. A synonym of **Retiniphyllum** (which *see*).

COMMIPHORA. A synonym of **Balsamodendron** (which *see*).

COMMON SWIFT MOTH (*Hepialus lupulinus*). Few insects are better known, at least by sight, than the commoner species of this genus, by reason of the peculiar oscillating, hovering flight which characterises the males. The majority of gardeners and farmers, however, do not appear to be aware of the destructive propensities at least of the insect here described. It is the commonest of the five species found in this country, and is quite as destructive as its near relative, the Ghost Moth (*H. Humuli*). As with that insect, the caterpillars of the Common Swift principally attack grass in meadows, lawns, and cricket-grounds, though they frequently forsake such food for Lettuce, Mint, Parsley, Cauliflowers, Brussels Sprouts, and other winter vegetables, as well as Strawberries.

The Moths are on the wing from the end of May until well into June. There is nothing conspicuous about their colouring, and though they are of fairly large size (1¾in. to 1¾in. in wing expanse), they would readily escape observation were it not for the irregular flight of the males at twilight when in search of their mates. The females are less frequently seen, preferring to lie hidden amongst the food-plants, where by an odour they exhale they attract the males. Pairing having taken place, the eggs are laid, and this act is accomplished while the insects are on the wing and flying steadily along. These Moths are somewhat variable as to colour, though usually brown or reddish-brown, with a whitish stripe from the tip to the inner margin, and another running from the base, while above the stripe is an elongated spot.

The caterpillars are slender, yellowish-white, and about 1in. long, and may be found from July at the roots of their food-plants, which quickly show signs of being preyed upon. They are very sensitive to the touch. The larvæ have sixteen feet—six claw-feet, eight sucker-feet, and a pair situate at the hinder extremity of the body. They feed from July or August until spring, though they are somewhat susceptible to frosts. When full-fed they approach the surface of the soil, and become pupæ in loosely-constructed silken cocoons. In this condition they are very restless, and may be observed wriggling about in their cocoons. They are yellowish-brown.

To deal with these pests is somewhat difficult, feeding, as they do, beneath the roots. In the case of grass, however,

1. Helle[illegible] [illegible]. 2. H. [illegible]. 3. H. viridi[illegible].

Common Swift Moth—*continued.*

applications of lime and soot (one part of the former to two parts of the latter) in spring would be of service. In gardens wood-ashes and soot scattered freely round the infested plants, and then hoed in, would render the ground undesirable. Insectivorous birds, again, would destroy large numbers if the soil round the plants could be hoed in spring as the larvæ were about to change into pupæ. *See also* **Otter Moth**, Vol. II.

COMMON YELLOW UNDERWING. *See* **Tryphæna.**

COMOSE. Growing in tufts; bearing a tuft.

COMPARETTIA. This genus embraces six species, natives of the Andes of South America. Sepals erecto-patent, the dorsal one free, the lateral ones connate, produced at base into a long, slender spur which is free of the petals; lip continuous with the base of the column, produced at base into two long, linear spurs, the lateral lobes rather broad, erect, the middle one spreading, very broad. To the species described on p. 366, Vol. I., the following should be added:

C. rosea is a form of *C. falcata.*

C. speciosa (showy).* *fl.* large and numerous; sepals and petals light orange, with a cinnabar glow; lip cinnabar, orange at base, the front lobe sub-quadrate and emarginate, about 1¼in. wide, with a very short claw and a small keel between the basal auricles; spur minutely pilose, upwards of 1½in. long; racemes loose. Ecuador. A beautiful species. (W. O. A. v., t. 233.)

COMPASS PLANT. *See* **Silphium laciniatum.**

COMPLANATE. Flattened vertically to a level surface above and below.

COMPLETE. Furnished with calyx, corolla, stamens, and pistils.

COMPSANTHUS. A synonym of **Tricyrtis** (which *see*).

COMPSOA. A synonym of **Tricyrtis** (which *see*).

COMPTONIA. Bentham and Hooker include this genus under **Myrica** (which *see*), the correct name being *M. asplenifolia.*

CONANTHERA. SYN. *Cumingia.* Three or four species, all Chilian, are included in this genus.

CONCHIUM. A synonym of **Hakea** (which *see*).

CONCHOCHILUS. A synonym of **Appendicula** (which *see*).

CONCHOPHYLLUM. A synonym of **Dischidia** (which *see*).

CONDALIA (named in honour of Condal, a Spanish botanist). ORD. *Rhamneæ.* A genus embracing half-a-dozen species of greenhouse or hardy, deciduous, rigid, spiny, American shrubs, with small, axillary flowers, and alternate, sub-sessile leaves. *C. microphylla* has been introduced, but is of no particular horticultural value.

CONDALIA (of Ruiz and Pavon). A synonym of **Coccocypselum** (which *see*).

CONDAMINEA (named in honour of De la Condamin, a celebrated traveller). ORD. *Rubiaceæ.* A small genus (two or three species) of stove shrubs or small trees, natives of Bolivia, Peru, and Colombia. Flowers rather large, in trichotomously corymbose cymes. Leaves large, shortly petiolate; stipules large, bipartite. *C. tinctoria* has been introduced, but is probably not now in cultivation.

CONE. *See also* **Strobile.**

CONGENERS. Plants of the same genus.

CONGESTED. Packed or arranged very closely together.

CONGLOMERATE. Clustered.

CONIANDRA. A synonym of **Kedrostis** (which *see*).

CONIOGRAMME. *See* **Gymnogramme.**

CONIUM ARRACACHA. A synonym of **Arracacha esculenta** (which *see*).

CONNECTIVE. That part of an anther which connects its two lobes; a continuation of the filament.

CONOCARPUS. A synonym of **Leucadendron** (which *see*).

CONOCLINIUM. A synonym of **Eupatorium** (which *see*).

CONOPHALLUS. Included under **Amorphophallus** (which *see*).

CONOPHARYNGIA. Included under **Tabernæmontana** (which *see*).

CONOSTEPHIOPSIS. A synonym of **Conostephium** (which *see*).

CONOSTYLIS (from *konos*, a cone, and *stylos*, a style; the style is conical at the bottom). ORD. *Hæmodoraceæ.* A genus embracing thirty-two species of greenhouse, herbaceous perennials, confined to Australia. Flowers usually dull yellow, more or less plumose-tomentose outside, in a terminal head, rarely lengthening out into a shortly dichotomous cyme. Leaves in distichous or crowded tufts on a short rhizome or on a tufted or branched stem. Several of the species have been introduced, but they are not in general cultivation.

CONOTRACHELUS NENUPHAR. *See* **Plum Insect Pests.**

CONOTRICHIA. A synonym of **Manettia** (which *see*).

CONVALLARIA. To the species described on p. 368, Vol. I., the following variety should be added. Several plants formerly known by this generic name are now referred to **Maianthemum** and **Polygonatum.**

C. majalis prolificans (prolific). An abnormal garden form, having the perianth more or less deeply divided and the lobes spreading. 1889. (R. G. 1292.)

CONVOLVULUS. Including *Rhodorhiza.* Sepals subequal, or the outer ones rarely broader; limb of the corolla plicate, five-angled or rarely five-lobed; peduncles axillary, one-flowered, or rarely cymosely many-flowered. To the species described on pp. 368-70, Vol. I., the following should be added. Several plants formerly classed hereunder are now referred to **Calystegia, Hewittia** (*see* **Palmia**), and **Ipomœa.**

C. californicus (Californian). *fl.*, corolla white, cream, or flesh-coloured, broadly funnel-shaped, 1½in. to 2in. long; peduncles shorter than the petioles. *l.* about 1in. long, varying from ovate or rounded-obovate to deltoid or sub-cordate and obtuse, or the later ones somewhat sagittate or hastate and acute, light green; petioles slender. Stems short and erect. Western California, 1888. Plant pubescent, half-hardy.

C. chrysorhizus (golden-rooted). A form of *Ipomœa Batatas.*

C. floridus (many-flowered). *fl.* white, or sometimes washed with pale rose, very numerous, in a terminal thyrse; corolla thrice exceeding the calyx, hairy outside. June to August. *l.* linear, undulated, attenuated to the petioles, obtuse and mucronulate, 3in. to 4in. long. Stems woody; branches canescent or pruinose. *h.* 6ft. Canary Islands, 1799. Greenhouse. SYN. *Rhodorhiza florida* (R. H. 1892, p. 156).

C. macrostegius (having a large covering). *fl.*, corolla pale yellow or cream-coloured, short and broad; peduncles 6in. to 8in. long, bearing two or three flowers within the ample bracts (1in. or more in length) and lateral flowers similarly bracteate. *l.* 4in. long and a little narrower. Lower California, 1895. Half-hardy under-shrub.

C. mechoacana (Mechoacan). A synonym of *Ipomœa Jalapa.*

CONYZA. *Eschenbachia* is synonymous with this genus.

CONYZA (of Schultes "Bipontinus"), in part. Synonymous with **Pluchea** (which *see*).

COOKIA (of Gmelin). A synonym of **Pimelea** (which *see*).

COOPERIA. Including *Sceptranthus.* This genus differs from *Zephyranthes* only in its stamens and in its long perianth-tube.

COPAI-YÉ WOOD. *See* **Vochysia guianensis.**

COPAL. *See* **Rhus Copallina.**

COPERNICIA. Syns. *Cryosophila* (of Blume), *Crysophila* (of Bentham and Hooker). The species are natives of Colombia, the West Indies, and Brazil. *C. nana* (Syn. *Crysophila nana*) has been introduced, but is not in general cultivation.

COPRINUS COMATUS, or **SHAGGY-CAP MUSHROOM.** This is a common and delicious Mushroom, frequently found in gardens in immense clusters, though oftener seen on paths and roads in newly-made districts. *C. comatus* should be eaten in the young stage, while the gills are whitish or purplish, for when

Fig. 275. Coprinus comatus.

specimens have assumed a black colour they are fit only for ketchup. This Mushroom is very distinctive (see Fig. 275), being of cylindrical form, with a snowy-white cap covered with woolly scales. It may be found throughout summer and autumn.

COPRIS LUNARIS. *See* **Unicorn Beetle.**

COPROSMA. Syn. *Marquisia.* Flowers regular, hermaphrodite or unisexual; corolla four- to nine-lobed, -toothed, or -parted. Fruit ovoid or globose, fleshy, with two or rarely four stones. Leaves opposite, ovate, oblong, rounded, or linear. The following is the typical form of the species to which the varieties given on p. 371, Vol. I., belong:

C. Baueriana (Bauer's). *fl.* ¼in. to ⅓in. long, capitate. *fr.* broadly ovoid, ¼in. to ⅓in. long. *l.* ½in. to 1½in. long, broadly oblong-obovate, rarely smaller and oblong-lanceolate, with recurved margins, pale below. New Zealand, 1866. A small tree or shrub.

COPTIS. About half-a-dozen species, natives of the North Temperate Zone, are included hereunder. Flowers whitish; sepals five or six, regular, petaloid, deciduous; petals five or six, small, hooded or linear; carpels numerous; scapes leafless, one- to three-flowered. Leaves radical, ternately dissected.

CORALLOBOTRYS (from *korallion*, coral, especially red coral, and *botrys*, a cluster; in allusion to the colour and shape of the inflorescence). Ord. *Vacciniaceæ.* A monotypic genus. The species is a greenhouse, epiphytal shrub, requiring similar culture to the epiphytal species of *Vaccinium.*

acuminata (taper-pointed).* *fl.* bright coral-red, corymbose; calyx lobes five; corolla ½in. long, globose-campanulate, with five recurved teeth; peduncle ½in. to ¾in. long. *l.* alternate, petiolate, lanceolate, acuminate, 5in. to 10in. long, obtusely serrated, cuneate at base; petioles ¼in. to ⅜in. long. Branches thick. *h.* 2ft. to 4ft. Khasia. Syn. *Epigynium acuminatum* (B. M. 5010).

CORCHORUS. *Mærlensia* is synonymous with this genus.

CORDIA. The species are broadly dispersed over the warmer regions of the globe, and are very plentiful in America. To those described on p. 372, Vol. I., the following variety should be added:

C. Greggii Palmeri (Gregg's, Palmer's variety).* *fl.* white, fragrant, in size and form resembling those of *C. Sebestena*, borne in terminal clusters. *l.* small, pubescent, toothed. *h.* 5ft. to 10ft. North Mexico, 1839. A showy shrub. (G. & F. 1889, ii., p. 233, f. 106.)

C. ipomœæflora (Ipomœa-flowered). *fl.* white or yellowish-white, loosely paniculate, resembling those of *C. superba*, but 1½in. in diameter. Summer. *l.* much confined to the branchlets, obovate-lanceolate, 12in. to 16in. long, 5in. broad, acute or acuminate, coarsely serrate-toothed. *h.* 12ft. to 14ft. Habitat unknown. Tree. (B. M. 5027.)

C. officinalis (officinal). A synonym of *C. Myxa.*

C. ulmifolia (Elm-leaved). *fl.* glomerate; peduncles axillary, adnate to the petiole at the base, or racemose. *l.* 2in. to 4in. long, ovate or ovate-lanceolate, acuminate, sharply serrulated above the base, scabrous above, velvety or pubescent beneath. Branchlets pubescent or velvety. *h.* 6ft. to 15ft. West Indies. Shrub.

CORDIERA. A synonym of **Alibertia** (which *see*).

CORDYLINE. Syn. *Tætsia.* The species are found in the East Indies, the Malayan Archipelago, Australia, New Zealand, and the South Pacific Islands, one being a native of Brazil. To the species and varieties described on pp. 372-5, Vol. I., the following should be added. There are many other garden forms of *C. terminalis.*

C. argenteo-striata (silvery-striated).* *l.* linear-lanceolate, bright green, striated and occasionally margined creamy-white, the bright green also relieved with streaks of silvery-grey. South Sea Islands, 1888. A form of *C. australis*, useful for table-decoration.

C. augustifolia (fine-leaved).* *l.* linear-lanceolate, arching, about 1½ft. long, 1in. broad, dark green, marked and margined with crimson and rose-colour. 1883. A good table-plant.

C. australis Doucetii (Doucet's). *l.* edged and striped with white. (I. H. xxxv., t. 40, under name of *C. indivisa Doucetiana.*)

C. a. rubra (red). *l.* bronzy, broader and more erect than in the type. 1892. Habit more compact.

C. a. Russellii (Russell's). *l.* dull brown, with a yellow midrib. 1897.

C. a. variegata (variegated). *l.* marked with longitudinal bands of creamy-white. 1881. A pretty form.

There is another variety, *lentiginosa* (I. H., t. 35).

C. Bartetii (Bartet's).* *l.* elliptic, reddish-bronze, bordered with red in the adult state; when young, brilliant red, flaked with brownish. 1886. A beautiful, garden variety.

C. Broomfieldii (Broomfield's). *l.* 1½ft. long, 2in. broad, green, margined and striped with white. Stem short, jointed, 1in. thick. South Sea Islands (?), 1896. (G. C. 1896, xx., p. 666, f. 115.)

C. Claudia. *l.* bronzy-green, flaked and margined with crimson. 1884.

C. cuprea (coppery). *l.* of a coppery brown, shaded with green; petioles salmon-rose. 1893. Probably a form of *C. terminalis.*

C. Diana. *l.* long-lanceolate, recurved, olive-green, margined, flaked, and striped with crimson-pink. 1883.

C. excellens (excellent).* *l.* bronzy, variegated with bright rosy-red, broad, oblong, drooping. 1885. A hybrid form of *C. terminalis.*

C. indivisa Dallieréana (Dallière's). An ornamental seedling variety, having the leaves striped with yellow. 1890. (I. H. xxxvii., t. 114.)

C. i. Doucetiana (Doucet's). A synonym of *C. australis Doucetii.*

C. Laingi (Laing's).* *l.* 8in. to 10in. long, 2in. to 2½in. broad; youngest ones pale green, with broad bands and margins of creamy-white, faintly tinged rose; older ones of a deeper green, bordered with crimson and white. 1882. A free-growing hybrid, useful for decorative purposes, as it bears changes of temperature better than many other kinds.

C. macrantha (large-flowered). A synonym of *Brocchinia cordylinoides.*

C. madagascariensis (Madagascar). *l.* green, long and narrow, acuminate, arching. Madagascar, 1884. A distinct form, of graceful habit.

C. norwoodiensis (Norwood). *l.* banded yellow, green, and crimson, the last-named colour being chiefly confined to the marginal portion; petioles bright carmine. 1885.

C. picturata (decorated). *l.* rich olive-green, flaked and striped with pink and crimson. 1883. An attractive form.

C. placida (placid). *l.* long, narrow-lanceolate, recurved, undulated, variegated with creamy-white. 1883.

C. Plutus. *l.* bronzy-green, flaked and margined with crimson 1884. An ornamental variety.

Cordyline—*continued.*

C. Rigoutsi (Rigouts'). This is a variegated seedling raised from *C. australis*. (I. H. 1896, p. 24, t. 50, under name of *Dracæna Rigoutsi*.)

C. Rumphii (Rumphius'). A synonym of *Dracæna Hookeriana*.

C. Thomsoniana (Thomson's).* A fine, bold, erect plant, having a head of long, bright green leaves. West Coast of Africa, 1882. A seedling from *C. terminalis*. (F. M. n. s. 441.)

C. venosa (veined). *l.* oblong-ovate, acuminate, many-ribbed, yellow-green, blotched and reticulated with dark green. Borneo, 1883. A pretty, dwarf form.

C. Williamsii (Williams'). *l.* large, oblong-lanceolate, acute, spreading and recurved, dull green, irregularly striped with chocolate, white, rose, cinnamon, and yellow. Polynesia, 1883. A distinct plant.

CORE. A popular name for the bony endocarp of a pome, containing the seeds.

COREMA. *Euleucum* and *Oakesia* (of Tuckerman) are synonymous with this genus.

FIG. 276. COREOPSIS GRANDIFLORA.

COREOPSIS. Tickseed. Including *Agarista* (of De Candolle), *Calliopsis*, *Chrysostemma*, and *Diplosastera*. Of this genus about fifty-five species are known, natives of North and South America, tropical Africa, and the Sandwich Islands. To those described on pp. 376-8, Vol. I., the following should be added. *See also* **Leptosyne** (which is kept distinct by Dr. Asa Gray).

C. abyssinica (Abyssinian).* *fl.-heads* of a rich yellow, about 1in. in diameter, freely produced; ray florets ¼in. broad; inner involucral scales coloured, hispid. *l.* thick, pinnatisect; lateral leaflets three pairs, lanceolate or linear-lanceolate, deeply toothed or almost pinnati-partite; terminal one larger. Stem erect, 2ft. or more in height, corymbose. Abyssinia, 1895. Annual.

C. aristosa mutica (beardless). *fl.-heads* bright deep yellow, without awns. *l.* turning bronzy. *h.* 3ft. United States, 1893. (R. G. 1893, p. 439.)

C. Atkinsoniana (Atkinson's). *fl.-heads* orange-yellow, spotted with brown in the centre; pappus none or minute. Autumn. *l.* all once or twice pinnately divided; lobes linear or nearly so. Stem 2ft. to 4ft. high. North America. Annual or perennial. (B. R. 1376.) SYN. *Calliopsis Atkinsoniana*.

C. ferulæfolia (Ferula-leaved). A synonym of *Bidens ferulæfolia*.

Coreopsis—*continued.*

C. japonica (Japanese). *fl.-heads* canary-yellow. *l.* linear-lanceolate. Japan, 1895. A compact-growing species.

C. longipes (long-footed). A synonym of *C. grandiflora*. See Fig. 276.

C. palmata (palmate). *fl.-heads* orange-yellow, large; ray florets obovate-oblong; involucral bracts all united at the base. July to October. *l.* palmately three-cleft, cuneiform in outline, sessile, the undivided basal portion little wider than the rather broadly linear lobes. *h.* 1ft. to 2ft. North America, 1823. Plant glabrous, rigid. Perennial. SYN. *C. præcox* (R. H. ser. ii., iv., p. 265).

C. parviflora (small-flowered). A synonym of *Cosmos sulphureus*.

C. præcox (early). A synonym of *C. palmata*.

CORETHROGYNE (from *korethron*, a broom, and *gyne*, a female; in allusion to the brush-like tuft of bristles on the style-appendages). ORD. *Compositæ*. A small genus (three species) of rather low and Aster-like, hardy perennials, cottony-tomentose when young, confined to California. Flower-heads large and showy, solitary, terminal; ray florets violet-blue or purple; disk yellow, often changing to purplish; pappus tawny or ferruginous. Leaves sessile, entire or serrated. For culture of *C. obovata*, the only species yet introduced, *see* **Aster.**

C. obovata (obovate). *fl.-heads* having the ray florets violet, varying to white suffused with pink. Summer. *l.* obovate or spathulate, obtuse, sparsely toothed above; those of the ascending branches small, oblong to linear-lanceolate. Stems decumbent, 1ft. or more in length. 1873. SYN. *C. spathulata*.

C. spathulata (spoon-shaped). A synonym of *C. obovata*.

CORIARIA. About five species of usually glabrous shrubs or under-shrubs compose this genus. To those described on p. 378, Vol. I., the following should be added:

C. japonica (Japanese). *fl.* bright rose or coral-red, sub-globose, ¼in. in diameter; racemes springing from the opposite leaf-scars of the branches, two or three together, all female or one male, 1½in. to 3in. long. June. *l.* ovate or ovate-lanceolate, acuminate, 1in. to 2in. long, two-nerved. Japan. 1896. A low, branching, half-hardy shrub. (B. M. 7509.)

C. ruscifolia (Ruscus-leaved). The correct name of *C. sarmentosa*.

C. terminalis (terminal). This differs from *C. nepalensis* in having terminal inflorescences (instead of axillary or in the forks) and five- to nine-nerved leaves. Himalayas and China. 1897.

CORK-WOOD. *See* **Anona palustris.**

CORM. A solid bulb. The enlarged base of the stem of a herbaceous plant, in which is stored a reserve of starch or other food-material; a pseudo-bulb. In substance a Corm resembles a tuber, but it is generally more upright; it produces from its upper surface leaves and buds, and from its lower, roots; *e.g.*, the Corms of Cyclamens and Crocuses. Corms are popularly but erroneously called **Bulbs** (which *see*).

CORNELIAN CHERRY. *See* **Cornus mas.**

CORNICULATE. Having an appendage or a process resembling a little spur or horn.

CORN MARIGOLD. *See* **Chrysanthemum segetum.**

CORNUS. About twenty-five species, distributed over Europe, temperate Asia and America, Mexico, and the Himalayas, are included in this genus. To those described on pp. 378-9, Vol. I., the following should be added:

C. brachypoda (short-stalked). A synonym of *C. macrophylla*.

C. capitata (headed). The correct name of *Benthamia fragifera*.

C. corynostylis (club-styled). *fl.* borne in sub-globose, white, silky-woolly corymbs; petals narrow, rather large; style club-shaped, equalling the filaments. *l.* opposite, ovate, ovate-oblong, or oblong-elliptic, acuminate, green or slightly woolly beneath. Himalayas, 1896. (R. G. 1896, pp. 11, 286, t. 54, f. 4.)

C. florida flore-rubra (red-flowered). In this variety the flowers are tinted with bright red. 1889. There is also a weeping form (*pendula*).

C. Kousa (Kousa). The correct name of *Benthamia japonica*.

C. macrophylla (large-leaved). *fl.* white; calyx tube urn-shaped, whitish with appressed hairs; panicles terminal, erect, often 4in. to 5in. in diameter. July. *l.* opposite or alternate, 6in. long, 3½in. broad, or larger, acuminate at apex, glaucous beneath, tinted with orange-red in autumn; petioles 1in. long. *h.* 40ft. Kumaon, 1827. SYN. *C. brachypoda*. There is a silvery-variegated form (*variegata*).

Cornus—*continued.*

C. mas Mietzschii (Mietzsch's). *l.* marbled, striped, and spotted with white, grey, and green. 1894.

C. sanguinea. Gaten-tree; Gater-tree; Pegwood; Prickwood. There is a variety—*foliis aureo-marginatis grandifolia*—which is remarkable for its very large, golden-variegated leaves (also for its unnecessarily cumbrous name). 1889.

C. sibirica (Siberian). A synonym of *C. tartarica.*

C. stolonifera Rosenthali (Rosenthal's). This form is variegated in a similar manner to *C. sibirica Spathi.*

C. tartarica (Tartar). *fl.* white, disposed in corymbs at the ends of the branches. July. *fr.* white. *l.* oblong-oval, veined, white on their under-sides. *h.* 8ft. Siberia, 1824. SYN. *C. sibirica.*

C. t. Gouchalti (Gouchalt's). A garden form with variegated leaves. 1888.

C. t. Spaethi (Spaeth's).* *l.* large, striped with yellow, broadly margined with bright golden-yellow. 1889. One of the best of hardy, variegated shrubs.

CORNUTE. Horn-shaped, or furnished with a horn-like process.

CORN VIOLET. *See* **Specularia hybrida.**

CORONILLA. This genus embraces about a score species, natives of Europe, North Africa, and Western Asia. To those described on p. 380, Vol. I., the following should be added:

C. cappadocica (Cappadocian). The correct name of *C. iberica.*

C. pentaphylla (five-leaved). *fl.* yellow, ten to twenty in an umbel. June and July. *l.*, leaflets five to seven, cuneiform, mucronate, often emarginate; stipules ovate, mucronate, deciduous. *h.* 2ft. to 3ft. Algiers, 1700. A glabrous greenhouse shrub.

C. Securidacea (Securidacea). A synonym of *Securigera Coronilla.*

CORREA. SYN. *Mazeutoxeron.* Five species, according to Bentham, in the "Flora Australiensis," natives of South-Eastern Australia, are included in this genus. To the information given on pp. 380-2, Vol. I., the following should be added:

C. rufa (reddish). A synonym of *C. alba.*

C. speciosa (showy).* *fl.* red, varying to white or yellowish-green, terminal, shortly pedicellate and pendulous, or a few rarely erect, solitary or two or three together; corolla cylindrical or slightly campanulate, ¾in. to 1¼in. long. Early summer. *l.* very shortly petiolate, varying from broadly ovate or cordate to narrow-oblong or lanceolate, ¾in. to 2in. long. A tomentose shrub of variable height. (A. B. R. 653; B. M. 1746; B. R. 26.) The following are regarded by Bentham as merely forms of, or garden hybrids raised from, this species: *C. bicolor, C. cardinalis* (B. M. 4912), *C. Harrisii, C. longiflora, C. pulchella* (B. 152; B. M. 4029; B. R. 1224), *C. virens* (B. M. 1901; B. R. 3), *C. viridiflora* (A. B. R. 436).

CORTADERIA (*Cortadora* is the name used for the Pampas Grass and its congeners by the Spanish-speaking people of South America). ORD. *Gramineæ.* A genus embracing four or five species of greenhouse or hardy Grasses, natives of the Andes and New Zealand, and closely allied to **Gynerium** (which *see* for culture of the following species).

C. argentea is the correct name of *Gynerium argenteum* according to Dr. Stapf (in G.C. 1897, ii., 396).

C. jubata (maned). *fl.*, spikelets ¼in. long, three- to five-flowered, the males nearly glabrous, the females silky; panicle 1ft. to 2ft. long, inclined or nodding, laxly plumose, pale straw-coloured suffused with purple; branches flexuous, the lower ones 1ft. or more in length. October. *l.* drooping on all sides, long, slender, ending in filiform points. Upper internodes more than 1ft. long. Andes, 1895. A half-hardy perennial with biennial culms. (B. M. 7607.)

CORYANTHES. About ten species, all tropical American, have been referred to this genus. To those described on p. 382, Vol. I., the following should be added:

C. Albertinæ (Albertina's). A form of *C. maculata.*

C. Bungerothii (Bungeroth's). *fl.* very large; sepals pale green, dotted with red, the dorsal one 2½in. long, the lateral ones 6in. long; lip orange, spotted with reddish-brown inside, having the front part of the very large, hood-like organ prolonged down to the level of the bucket-shaped part, which is yellow, shading to yellowish-brown and marked inside with large, reddish-brown spots. May. Venezuela, 1890. A fine species. (L. vi., t. 224.)

C. leucocorys (white-helmeted). *fl.*, dorsal sepal greenish-yellow, tinted and striped with purplish-brown, 1¾in. across, the lateral ones 2in. wide, over 4in. long, similarly coloured, curiously rolled over; petals white, obscurely purple-striped, 2¾in. long, ½in. broad, falcate; pouch of lip whitish, marbled with rosy-purple, the hood ivory-white. June. Peru, 1891. (L. vii., t. 293.)

C. macrantha. A flower of this species, which is fully described in Vol. I., is shown in Fig. 277.

Coryanthes—*continued.*

C. macrocorys (large-helmeted). *fl.* large, pale yellowish-white, spotted and dotted with purple, and having a very elongated, thimble-shaped hood at the base of the lip, streaked and spotted with purple. Peru, 1892. A very distinct species. (L. viii., t. 342.)

C. maculata punctata (dotted). *fl.* large; sepals and petals ochre-yellow, spotted wine-purple; lip with a hood-shaped body near the base, to which a large, helmet-shaped, pedunculate appendage is attached, the hood yellowish, spotted and blotched wine-purple, the pouch more heavily marked. October and November. Demerara. (B. R. 1793; W. O. A. iii. 98.)

C. m. vitrina (greenish). *fl.* of a light greenish-yellow. 1895.

Other varieties are: *Albertinæ* (F. d. S. viii., t. 755), which is practically identical with *punctata*; and *Parkeri* (B. M. 3747), in which the hypochil of the lip is of a dingy brown-purple.

FIG. 277. FLOWER OF CORYANTHES MACRANTHA.

C. Mastersiana (Dr. Masters'). *fl.* probably yellow, stained with red, the hypochil of the lip deep glowing red, in a spike 1½ft. to 2ft. high; lateral sepals 3½in. to 4in. long; lip consisting of a thick bell-shaped hypochil, a thick fleshy mesochil, and a large, bell-shaped epichil. Pseudo-bulbs two-leaved. Colombia, 1891.

C. Parkeri (Parker's). A form of *C. maculata.*

C. punctata (dotted). A form of *C. maculata.*

C. Wolfi (Dr. Wolf's). *fl.* yellow, mottled and stained with brownish-red, large, three to six in a spike, about 1½ft. high. February and March. Colombia, 1891.

C. elegantium (SYN. *C. elegantissimum*) and *C. Fieldingi* have also been introduced, but are very rare.

CORYBAS. A synonym of **Corysanthes** (which *see*).

CORYCIUM (from *korys*, a helmet; in allusion to the shape of the flowers). ORD. *Orchideæ.* A genus embracing about ten species of greenhouse, terrestrial, leafy Orchids, with undivided tubers, natives of South Africa. Flowers small or mediocre, numerous in a dense spike; dorsal sepal and petals connate, forming a helmet; lip erect or incurved, the claw adnate to the column. Leaves narrow, flat or undulate-crisped. The genus is represented at Kew by *C. orobanchoides* (B. R. 1838, t. 45), which, however, is not in general cultivation, being kept alive only with difficulty.

CORYDALIS. TRIBE *Fumarieæ* of ORD. *Papaveraceæ.* Of the dozen species embraced in this genus, six are North American and the rest inhabit West Asia or the Himalayas. To those described on p. 383, Vol. I., the following—all perennials—should be added:

C. aurea speciosa (showy). A synonym of *C. pallida.*

C. canadensis (Canadian). A synonym of *Dicentra canadensis.*

Corydalis—*continued.*

C. capnoides (smoke-like). A synonym of *C. lutea.*

C. c. alba (white). A garden synonym of *C. lutea.*

C. fabacea (Faba-like). *fl.* purple or white, somewhat numerous; bracts ovate, acute, longer than the pedicels. March to May. *l.* three or four, petiolate, biternately cleft; segments oblong, rather obtuse. Stems almost simple, erect, bearing scales below the leaves. *h.* 3ft. Europe, 1815. Tuberous. SYN. *Fumaria fabacea.*

C. fungosa (Fungus-like). A synonym of *Adlumia cirrhosa.*

C. Gortschakovii (Gortschakow's). *fl.* golden-yellow, ¾in. long; spur equalling the obtuse petals; racemes elongated, dense, terminal. *l.* bipinnatisect, the radical ones 5in. to 6in. long; segments of the lower leaves obovate-oblong, with a few deep teeth. Stem erect, leafy, very simple or branched from the base, 1ft. to 1½ft. high. Alatau and Turkestan, 1885. (R. G. 1183.)

C. longiflora (long-flowered). *fl.* pale rose-coloured, disposed in an elongated raceme; spur nearly 1in. long (longer than the pedicels), slender, subulate, slightly incurved at apex, acute; bracts oblong, entire. April. *l.* biternately cleft; segments tripartite; lobes oval-oblong. Stems simple, bearing scales. *h.* 9in. Altai, &c., 1832. Tuberous. (B. M. 3230.)

C. pallida (pale). *fl.*, sepals very small; corolla golden-yellow, with a pale brown patch on the dorsal petal, 1in. long; racemes 1in. to 5in. long, many-flowered. March. *l.* tripinnatisect; leaflets very variable, oblong, obovate, or cuneate, variously cut. *h.* 1ft. to 1½ft. China and Japan, 1884. (B. M. 6826.) SYN. *C. aurea speciosa* (R. G. 1861, 343).

C. Sewerzovi (Sewerzow's). *fl.* few, distant, on slender pedicels; corolla golden-yellow, with a brownish tip to the spur, the tube gibbously convex below. June. *l.* glaucous, rather fleshy, the lower ones opposite or in a false whorl, 9in. long or less, pinnatisect, petiolate; cauline ones large, sessile, broadly cuneate. *h.* 8in. to 12in. Western Turkestan, 1885. (B. M. 6896; R. G. 1077.)

C. tomentella (slightly tomentose).* *fl.* bright yellow, tinged with green at the tips, shortly pedicellate, disposed in simple, erect spikes 6in. to 8in. long. May and June. *l.* bipinnatisect, with oval lobes, very glaucous, pubescent. Yunnan, China, about 1894. A very good and distinct species.

C. tuberosa. This is the correct name of the plant grown in gardens and described on p. 383, Vol. I., as *C. cava.*

C. t. alba (white). The correct name of *C. albiflora.*

CORYDANDRA. A synonym of **Galeandra** (which *see*).

CORYLUS. Seven species, widely distributed over the North temperate regions, are included hereunder.

The larvæ of certain moths are sometimes very prevalent on the foliage of these trees or bushes, and unless checked work serious damage by devouring the leaves and the young tender shoots. The caterpillar most in evidence is the larva of the Winter Moth (*Cheimatobia brumata*), which should be ousted by the use of Paris Green (1oz. to twenty gallons of water). The liquid should be constantly agitated while spraying with this powerful poison.

C. humilis (dwarf). A synonym of *C. americana.*

Varieties. The best of the Cob Nuts are the following:

Atlas Cob. Nuts of very large size, shells thick, and kernel of fair quality. Worth growing for its enormous, large nuts, which are freely produced.

Daviana. Nut of medium size, shell very thin and very brown in colour, with a kernel of fine flavour. A good grower and free-bearer.

Duke of Edinburgh. Nut large, shell thick, kernel of high flavour. A variety of great promise.

Merveille de Bollwyller. Nut very large, with thick shell, nearly covered by the husks. Flavour excellent. A vigorous and great bearer.

Other good varieties are: BRUNSWICK EMPEROR, LOUIS BERGER, PRIZE EXHIBITION COB, and PEARSON'S PROLIFIC.

In Filberts, the following varieties, in addition to those already given in Vol. I., may be recommended:

Prolific. Nuts of medium size, covered with a pretty mossy husk, in very large bunches; flavour excellent. A very ornamental variety.

True Kentish. Nuts of medium size. Undoubtedly the finest-flavoured Filbert; but the tree is somewhat tender, and not a free bearer.

CORYMBIS (from *korymbos*, a corymb; in allusion to the disposition of the flowers). SYNS. *Chloidia, Corymborchis, Hysteria, Macrostylis* (of Breda), *Rhynchanthera* (of Blume). ORD. *Orchideæ.* A genus embracing six or seven species of tall, leafy, stove, terrestrial Orchids,

Corymbis—*continued.*

broadly dispersed through the tropics. Flowers mediocre or rather large, corymbose, sub-sessile; sepals, petals, and lip linear, the lip channelled, dilated at apex; column long, erect. Leaves ample. *C. veratrifolia* is in cultivation at Kew, but the genus is very little known in gardens.

CORYMBORCHIS. A synonym of **Corymbis.**

CORYNELLA (a diminutive of *koryne*, a club; in allusion to the shape of the style). SYN. *Corynitis.* ORD. *Leguminosæ.* A small genus (three or four species) of stove shrubs, natives of the West Indies, with purplish flowers and impari-pinnate leaves. *C. polyantha* has been introduced, but is probably no longer in cultivation.

CORYNITIS. A synonym of **Corynella** (which *see*).

CORYNOCARPUS. To the species described on p. 385, Vol. I., the following variety should be added:

C. lævigatus aureo-marginatus (golden-margined). *l.* broadly bordered with golden-yellow. 1886. An ornamental variety, of compact habit.

CORYPHA. SYN. *Gembanga.* Of this genus about half-a-dozen species, natives of tropical Asia and the Malayan Archipelago, have been enumerated. Flowers small, hermaphrodite; calyx cup-like, three-toothed or three-lobed; petals three; stamens six; spadix solitary, erect, paniculately much branched; spathes many, tubular, sheathing the peduncle and branches. To the species described on p. 386, Vol. I., the following should be added:

C. decora (decorative). A garden synonym of *Livistona inermis.*

C. dulcis (sweet). A synonym of *Brahea dulcis.*

C. elata (tall). *fl.* in scattered fascicles on the rather stout, spreading branches of the spadix, which is about a quarter the height of the trunk. *l.* 8ft. to 10ft. in diameter, eighty- to one-hundred-cleft to about the middle; lobes ensiform, obtuse or bifid; petioles 6ft. to 12ft. long, spirally arranged. Trunk 60ft. to 70ft. high, 2ft. in diameter. India, 1825.

C. macropoda (large-stalked). *l.* palmately flabellate, 12ft. to 20ft. in diameter, divided to the middle; petioles 18ft. to 25ft. long, slender, as thick as a man's arm at the base; spines black. Andaman Islands. Plant stemless.

C. minor (lesser), of Jacquin. A synonym of *Sabal Adansonii.*

C. Palmetto (Palmetto). A synonym of *Sabal Palmetto.*

C. Taliera (Taliera). *fl.* in close clusters; spadix 20ft. or more in height; primary branches with ascending tips. *l.* 6ft. long, 15ft. broad, ninety- to one-hundred-cleft; lobes deeper and broader than in *C. umbraculifera*, the central ones 3ft. to 3½ft. long, the basal ones overlapping; petioles 5ft. to 10ft. long, not spirally arranged. Trunk about 30ft. high. Bengal, 1823.

C. Woganii is in the Kew Collection, but is not in general cultivation.

CORYSANTHERA. A synonym of **Rhynchotechum** (which *see*).

CORYSANTHES. SYNS. *Corybas, Nematoceras.* Flower solitary, sessile within the leaf or very shortly pedicellate, with a small, subtending bract usually close to the leaf.

COSBÆA COCCINEA. A synonym of **Schizandra Hanceana** (which *see*).

COSMEA. A synonym of **Cosmos** (which *see*).

COSMIBUENA. SYN. *Buena.* This genus includes half-a-dozen species, natives of tropical America. Leaves petiolate, somewhat succulent.

COSMOPHYLLUM. A synonym of **Podachænium** (which *see*).

COSMOS. SYN. *Cosmea.* This genus embraces about ten species, mostly tropical American. To those described on p. 386, Vol. I., the following should be added:

C. atrosanguineus (dark bloody). A form of *C. diversifolius.*

C. bipinnatus albiflorus (white-flowered).* A variety with white flowers freely produced on the long growths. 1890. See Fig. 278.

C. diversifolius atrosanguineus (variable-leaved, dark bloody). *fl.-heads* dark blood-purple, ample, on very long peduncles; ray florets elliptic, three-toothed at apex; peduncles 1½ft. long. September. *l.* long-petiolate, pinnate, the lower ones 8in. to 9in. long; pinnæ five to seven, the lower ones 2in. to 2½in. long. *h.* 3ft. Mexico, 1835. Hardy perennial. (B. M. 5227.)

C. hybridus (hybrid). *fl.-heads* white or pale rose-coloured, 2½in. in diameter, disposed in large, terminal corymbs. *l.* finely cut. *h.* 6ft. to 7ft. Mexico, 1883. A very attractive annual.

Cosmos—*continued.*

C. spectabilis (showy). A garden hybrid. 1892. (R. H. 1892, p. 372, f. 114-15 and Plate.)

C. sulphureus (sulphur-coloured). *fl.-heads* sulphur-yellow; outer involucral scales appressed, shorter and narrower than the inner ones. September and October. *l.* bipinnatipartite; lobes lanceolate, mucronate, somewhat scabrous on the margins; petioles ciliated. Stems pilose. *h.* 2ft. Mexico, 1799. Hardy perennial. SYN. *Coreopsis parviflora.*

FIG. 278. COSMOS BIPINNATUS ALBIFLORUS.

COSSUS LIGNIPERDA. *See* **Goat-Moth.**

COSTUS. SYNS. *Banksea, Gissanthe, Hellenia, Jacuanga, Planera* (of Giseke). All the species of this genus are tropical; they are found in America, Africa, Asia, and Australia. To those described on p. 387, Vol. I., the following should be added. *P. albescens, P. cinereus,* and *P. lucidus,* introduced in 1868, are apparently only garden varieties.

C. cylindricus (cylindrical). *fl.* yellow, 1in. long, the lobes oblong; spike cylindrical, 4in. to 6in. long; bracts scarlet, very numerous. *l.* spathulate-elliptic, acute, glaucous beneath, yellowish-ciliated. *h.* 6ft. or more. Trinidad. A variety from Martinique has blue flowers and purple bracts.

C. discolor (parti-coloured). *fl.*, calyx and stamens purple; corolla lobes white, lanceolate; lip white, yellowish in the middle, large, three-lobed; spike inclined, oval-oblong; bracts red and green, ovate. June. *l.* elliptic-oblong, acute, sub-sessile, purplish beneath, yellow-ciliated. *h.* 4ft. Brazil, 1823.

C. Englerianus (Engler's). *fl.* white and yellow, small, produced in sessile spikes. *l.* elliptic, obtuse, fleshy, dark green. Stems short, decumbent. Tropical Africa, 1892. SYN. *C. unifolius.*

C. Lucanusianus (Dr. Von Lucanus'). *fl.* purple, with a yellow middle lobe to the lip, disposed in terminal heads. *l.* lanceolate, acuminate, white beneath. Cameroons, 1892. A tall-growing species. (R. G. 1379.)

C. musaicus (mosaic-marked). *l.* obliquely-lanceolate, 3in. to 4in. long, the centre dark green, the rest tessellated with silvery-grey. Congo, 1887.

C. pictus (painted). *fl.* yellow, with a purple-variegated, erect, three-lobed lip; spike few-flowered; bracts broadly ovate, green, appressed. July. *l.* lanceolate, pilose above. *h.* 2ft. Mexico, 1832. (B. R. 1594.)

C. unifolius (solitary-leaved). A synonym of *C. Englerianus.*

COTONEASTER. Rockspray. Including *Nagelia.* This genus comprises about fifteen species, natives of Europe, North Africa, Central and West Asia, Siberia, the mountains of the East Indies, and Mexico. Fruit small, red or dark-coloured.

Seeds of Cotoneasters germinate more freely if sown in a moderate heat immediately they are gathered. If kept until the following spring they should be placed in a cool room in preference to a warm one, as they are liable to get very dry, and vegetation is thereby hindered. The seed may be sown

Cotoneaster—*continued.*

in drills or broadcast, in beds slightly raised above the level of the ordinary ground, and thinly covered with fine soil. The ground should never be allowed to become dry, or the seed will germinate very irregularly.

To the species described on p. 387, Vol. I., the following should be added:

C. affinis (related). A synonym of *C. buxifolia.*

C. Barbeyi (Barbey's). *fl.* green and red, numerous, in an almost globular panicle; corolla about 1in. long. *l.* 3in. long, glaucous. Stem tall, branched. Arabia, 1893.

C. congesta (congested). A synonym of *C. microphylla glacialis.*

C. Fontanesii (Desfontaine's). *fl.* white, disposed in small corymbs. *fr.* bright coral-red, large, round. *l.* oval-elliptic, greyish-green and glabrous above, silvery-silky beneath. Branches pubescent. 1886. This makes a round, compact bush about 3ft. high. (R. H. 1867, p. 33.)

C. horizontalis (horizontal). *fl.* rose-coloured, large. Spring. *fr.* bright vermilion, very ornamental. *l.* small, regularly disposed, many of them turning bright red in the autumn. Branches stout, almost horizontal, somewhat frond-like. China, 1879. Deciduous. (R. H. 1879, p. 136.)

C. microphylla glacialis (ice-loving). *fl.* often pink, smaller than in the type. *l.* glabrous above, glaucous beneath. Himalayas (up to 14,000ft.), 1868. SYN. *C. congesta* (Ref. B. 51).

C. pannosa (felt-like). *fl.* white with violet stamens, disposed in compact corymbs. *fr.* ochre-red at first, becoming vermilion. *l.* oval or oblong, mucronate, ¾in. to 1¼in. long, green and pubescent above, covered beneath with a thick coating of silvery-white down. *h.* about 6ft. Yunnan, China, 1898.

C. prostrata (prostrate). A synonym of *C. rotundifolia.*

C. reflexa (reflexed). *fl.* white, numerous, in erect, umbelliform corymbs; petals orbicular. April. *fr.* of a beautiful reddish-carmine, ripening in August. *l.* ovate or ovate-lanceolate, shortly acuminate, entire, reddish-green, pubescent above, tomentose beneath. Branches slender. Origin unknown. 1892. (R. H. 1892, p. 303.)

C. Roylei (Royle's). A garden synonym of *C. acuminata.*

C. sikkimensis (Sikkim). *fl.* white, in compound umbels. *fr.* bright coral-red, globose. *l.* elliptic, 4in. to 5in. long, 2in. to 2½in. broad, entire, mucronate, dull green above, grey beneath. Sikkim, 1890. A vigorous, deciduous shrub.

C. tomentosa (downy). *fl.* pink; calyx and peduncles woolly. June and July. *l.* elliptic, obtuse at both ends, woolly beneath. *h.* 4ft. Alps, 1759. Allied to *C. vulgaris.*

C. uniflora (one-flowered). *fl.* white; calyx glabrous; peduncles very short, one-flowered, and, as well as the calyx, highly glabrous. May and June. *l.* oval-oblong, attenuated at both ends, glabrous above, puberulous beneath. Altai, 1842.

COTTONIA (named in honour of Major-General Cotton, C.S.I., of the Madras Engineers, an indefatigable collector and cultivator of Orchids, who found *C. macrostachya* in Malabar). ORD. *Orchideæ.* According to the "Flora of British India," this is a monotypic genus, the species being an interesting stove Orchid, with a lip resembling that of *Ophrys aranifera.* For culture, *see* **Vanda.**

C. Championi (Champion's). A synonym of *Diploprora Championi.*

C. macrostachya (large-spiked). *fl.* ¾in. across; sepals subspathulate; petals dirty orange, with red streaks; lip dark purple, with a villous-golden margin; scape 1ft. to 1½ft. high, erect; branches few, tipped by short racemes. May. *l.* 5in. to 6in. long, ½in. to ¾in. broad, lorate, recurved, obtusely bilobed. Stem 4in. to 8in. long, leafy. India, 1840 and 1885. (B. M. 7099.) SYNS. *C. peduncularis* and *Vanda peduncularis* (P. F. G. iii., t. 253).

C. peduncularis (pedunculate). A synonym of *C. macrostachya.*

COTULA QUINQUELOBA. A synonym of **Lidbeckia lobata** (which *see*).

COTYLEDON. According to Bentham and Hooker, this genus comprises about sixty species, natives of West and South Europe, Africa, East Asia, the Himalayas, and

Cotyledon—*continued.*

Mexico. To those described on pp. 388-90, Vol. I., the following should be added :

C. Barbeyi (Barbey's). *fl.* green and red, 1in. long, numerous in a sub-globose panicle. *l.* fleshy, glaucous, 3in. long. Stems tall, branching. Arabia Felix, 1892. Allied to *C. orbiculata.*

C. carnicolor (flesh-coloured). *fl.* bright red when mature, pentagonal, ¼in. deep; racemes six- to twelve-flowered, 1½in. long and broad. *l.* about twenty in a dense rosette, oblanceolate-spathulate, 2in. long, ¾in. broad, glaucous-green with a decided reddish tinge. Stems two or three, 6in. high. Mexico. (Ref. B. 199.)

C. Corderoyi (Justus Corderoy's). *fl.*, corolla bright red at base, yellow upwards, urceolate, ⅜in. long; cyme trichotomous, fifteen- to twenty-flowered; scapes three or four to a rosette, 1¼ft. to 1½ft. long. *l.* ovate, 2in. to 2½in. long, ½in. thick, with a firm mucro, sixty to seventy in a dense rosette, pale whitish-green. Mexico (?), 1874. SYN. *Echeveria Corderoyi.*

C. cymosa (cymose). *fl.* yellow, ⅜in. deep, twenty to thirty in a dichotomously forked cyme with erecto-patent branches. *l.* twenty to thirty in a dense rosette, oblong-lanceolate, the largest 4in. or more in length and 1in. broad, narrowed to a broad base, and upwards to an acute point. *h.* 1ft. Mexico, 1855. (Ref. B. 68.)

C. edulis (edible). *fl.* white, Sedum-like, six to seven lines in diameter, shortly pedicellate, arranged along the upper side of the flexuose, spreading branches of the cymose panicles. *l.* nearly terete or obtusely trigonal, erect, whitish or glaucous-green, but without mealiness. Stems very short, thick. California (on dry banks near the sea in San Diego), 1883. The young leaves are eaten by the Indians. SYN. *Sedum edulis.*

C. farinosa (mealy). *fl.* yellow, tinged with green, scarcely pentagonal, ¼in. to ⅜in. long, twenty to thirty in a cyme, with spreading main branches. *l.* twenty to thirty in a dense rosette, ligulate-lanceolate, the longest 2½in. to 3in. long and ⅜in. broad, acutely pointed, white-farinose when young, fading to glaucous-green with a faint reddish tinge. Flowering branch 1ft. high, with small, cordate-amplexicaul leaves. California, 1855. (Ref. B. 71.)

C. globulariæfolia (Globularia-leaved). *fl.* white with a reddish tinge, ⅜in. deep, cleft half-way down; panicle thyrsoid, dense, with cymose branches, twenty- to forty-flowered. *l.* thirty to forty in a dense, sessile rosette, the outer ones obovate-spathulate, 2in. to 2½in. long, ½in. to ¾in. broad. *h.* 8in. Syria, &c., 1869. (Ref. B. 201.)

C. hispanica (Spanish). *fl.* reddish, in terminal cymes; calyx short; corolla tube much elongated, the limb five-parted; stamens inserted in the throat of the corolla. June and July. *l.* sub-terete, oblong, sparse, sessile. *h.* 6in. Spain and Barbary, 1796. An erect, hardy annual or biennial. SYN. *Pistorinia hispanica.*

C. mamillaris (nipple-like). *fl.* as in *C. hemisphærica.* June. *l.* 1½in. to 2in. long, sub-cylindrical, crowded round the apex or scattered on the short stem, glabrous. Stem short or scarcely any. South Africa, 1818. (B. M. 6020.)

C. nodulosa (noduled). *fl.* straw-yellow, tinged with red, ½in. long, pentagonal, four to six in a lax raceme 3in. to 4in. long. *l.* obovate-spathulate, aggregated at the apex of the stem in a dense rosette, the largest 2in. to 2½in. long and ¾in. broad, dull apple-green with a slight glaucous tinge, the edges tinged with red. Stem naked, 6in. to 8in. high; flowering branches 6in. to 9in. long, with ascending leaves. Mexico. (Ref. B. 56.)

C. nuda (naked). *fl.* pink below, straw-coloured upwards and within, pentagonal, nearly ½in. long, twelve to twenty in a moderately dense raceme. *l.* obovate-spathulate, twelve to fifteen aggregated towards the apex of the stem, the largest over 2in. long and 1in. broad. Stem 6in. to 8in. high; flowering branch 6in. to 12in. long, with ascending leaves. Mexico. (Ref. B. 57.)

C. pubescens (downy). *fl.* bright red on the outside when mature, yellow within, pentagonal, ⅜in. deep, fifteen to twenty-five in a spike, the upper ones dense. *l.* obovate-spathulate, eight to twelve aggregated towards the apex of the stem, 3in. to 3½in. long, 1in. to 1½in. broad, densely white-pubescent. Stems often 1ft. to 2ft. high and 1in. thick. Mexico. (Ref. B. 197.) SYN. *Echeveria pubescens.*

C. pulverulenta (powdery). *fl.* pale scarlet or coral-colour, in a dichotomous, fastigiate panicle. May. *l.* spathulate, acuminate, very powdery; those of the stem gradually diminishing. Stem 2ft. to 3ft. high. California. (Ref. B. 66.) SYN. *Echeveria farinosa* (of gardens).

C. pumila (dwarf). *fl.* brownish-red at base, orange above, otherwise as in *C. secunda*; raceme eight- to twelve-flowered, 2in. to 3in. long. *l.* fifty to sixty in a very dense rosette, 1½in. to 2in. long, ½in. broad, mucronate, pale glaucous-green, the older ones tinged with red at apex. Flowering branches 6in. to 9in. long. Mexico. Plant stemless. (Ref. B. 62.) SYN. *Echeveria pumila.*

C. Purpusii (Purpus's). This plant is closely related to *C. pulverulenta* (*Echeveria farinosa* of gardens), but differs in having narrow, angled, pyramidal, red (not yellow) flowers. Sierra Nevada, 1896. SYN. *Echeveria Purpusii* (R. G. 1896, p. 608, f. 97; G. C. 1896, xx., p. 698, f. 123).

Cotyledon—*continued.*

C. quitensis (from Quito), of gardens. *fl.* red, produced in racemes from December onwards. 1893. A dwarf, branched, compact-growing plant, altogether different from the true *C. quitensis* of Baker.

C. reticulata (netted). *fl.* whitish, scarcely ¼in. long, the stalks persistent and forming a "mop" of much-branched, spreading spines. *l.* ¼in. to ½in. long, terete, acute or mucronate, fascicled on wart-like, abortive branchlets and at the apex of the stem. Stem 6in. to 8in. high, 1in. to 2in. thick, simple or divided. South Africa, 1897. (G. C. 1897, xxi., p. 282.)

C. sedoides (Sedum-like). *fl.* pink, few, five-parted, nearly like those of a Sedum, but gamopetalous, large for the size of the plant, sub-sessile at the tips of the branches. Summer. *l.* oblong, convex, obtuse, glabrous. Stems somewhat creeping, glabrous. Pyrenees. A small, hardy annual. SYN. *Umbilicus sedoides.*

C. stolonifera (stolon-bearing). *fl.* yellow above, pink at base, with brown marking between, pentagonal, ½in. long, four to six in a close cyme. *l.* thirty to forty in a dense rosette, obovate-spathulate, the largest 2in. to 2½in. long, half as broad, pale bright green, ⅛in. thick. Stem short; flowering branches 6in. to 8in. long, with a few leaves less than 1in. long. Mexico. (Ref. B. 63.)

COUBLANDIA. A synonym of **Muellera** (which *see*).

COUCH GRASS (*Triticum repens*). A noxious weed, very troublesome on agricultural land, but it is not so difficult to eradicate from a garden. One of the most effectual modes is to heavily manure a piece of ground infested, and plant with Brussels Sprouts, Kale, or Broccoli. These make strong growth and large foliage that smother the Couch Grass. Other methods are careful forking out all pieces as they appear, and burning them at once. Much may be done by carefully collecting all pieces seen when digging the ground, and by preventing plants from going to seed.

COUMAROUNA ODORATA. A synonym of **Dipteryx odorata** (which *see*).

COUNTRYMAN'S TREACLE. *See* **Ruta graveolens.**

COUSSAPOA (from *Coussapoui*, the Caribbean name of two of the species). ORD. *Urticaceæ.* A genus of stove, milky trees or shrubs, sometimes climbing over trees or epiphytal; eighteen species have been described, natives of tropical South America, but according to Bentham and Hooker this number might be reduced. Flowers dicœcious, borne in a globose head; peduncles solitary or in pairs, axillary, the male heads few-flowered, often dichotomously paniculate, the female peduncles shorter, bearing one large head or a few clustered smaller ones. Fruit included, oblong. Leaves alternate, petiolate, entire, coriaceous, penniveined or three-nerved. For culture, *see* **Ficus.**

C. dealbata (whitened).* The correct name of the plant described on p. 12, Vol. II., as *Ficus dealbata.*

COUTAREA. This genus embraces about five species. Flowers showy, odorous, terminal, solitary or in cymes of three; calyx and corolla each with five or six lobes; stamens five or six. Leaves opposite, shortly petiolate, membranous, ovate, acuminate; stipules short, acute. To the species described on p. 390, Vol. I., the following should be added :

C. Scherffiana (Scherff's).* *fl.* white, solitary, disposed in leafy cymes; corolla 2in. long, tubular-campanulate, ribbed, with spreading lobes. *l.* shortly petiolate, ovate, acuminate, attenuated at base, flat, shining; stipules broadly triangular. Branches divaricate. Colombia, 1876. A tall shrub. (I. H. 1878, t. 321.)

COUVE TRONCHUDA (*Brassica oleracea costata*). An excellent vegetable, not so well known in British gardens as its merits warrant. For first supplies, seeds should be sown early in February in gentle heat, and when large enough to handle the seedlings should be pricked in rich soil, afterwards gradually hardening the plants off and planting out in deeply-dug and rich ground, 3½ft. apart each way. About the middle of March, a further sowing should be made in a cool frame or warm border outside, protecting the seeds from birds, and transplanting the plants when large enough to liberally-manured ground, at the distance apart named above. As the plants grow, diluted liquid manure applied occasionally will be of considerable value, so will also an application of 1oz. of nitrate of soda per square yard. Either or both of these will induce strong growth, a point to be aimed at, as the midribs of the large leaves are the best part of the vegetable when cooked in the same way as Sea Kale, and are of a most agreeable and distinct flavour.

COVELLIA. Included under **Ficus** (which *see*).

COW-BELL. *See* **Silene inflata.**

COW-HERB. *See* **Saponaria Vaccaria.**

COWHORN ORCHID. *See* **Schomburgkia tibicinis.**

COWSLIP (*Primula veris*). When cultivated in gardens the plant produces very large trusses, which are sweetly scented. The culture is similar to that of the common Primrose and Polyanthus.

COW'S LUNGWORT. *See* **Verbascum Thapsus.**

COW-TREE. *See* **Brosimum.**

CRACKING OF FRUIT. This condition is very familiar alike on fruits grown under glass and in the open. In the former case, Grapes are chiefly affected, and as such berries are both unsightly and not very saleable, an endeavour must be made to combat the evil. Cracking usually arises in the case of Grapes from imperfect ventilation, overfeeding, and an excess of moisture in the atmosphere and at the roots. It is especially prevalent when such conditions follow a somewhat dry period. Frequently a strong application of natural or of chemical manure will induce thin-skinned varieties to Crack badly. A similar condition may be induced by a saturated border, which previous to watering was rather dry. Again, Cracking may be the result of fungus attacks, to which the conditions named above may predispose the Vines.

With hardy fruit, Cracking is very common upon Apples and Pears. Then it is due to the presence of a well-defined fungus, *Fusicladium dendriticum*, to which attention has already been directed under **Apple and Pear Scab.**

CRACK WILLOW. *See* **Salix fragilis.**

CRANBERRIES. There are several varieties of Cranberries (*Oxycoccus*), notably the following American sorts—Bugle, Bell, Cherry, and the one known as the American Cranberry (*O. macrocarpus*). The fruit is rather sour, but when cooked in tarts, &c., with sufficient sugar to sweeten, it is usually appreciated. When once established, little or no further attention is required, except preventing other trees or bushes from smothering the tough, wiry growths. The fruit, which is ripe in September, varies in colour from red to purple, and in form from round to oval. Propagation is usually effected by division in the early spring.

In England the cultivation of the Cranberry has not been seriously attempted, though those best capable of judging contend that it could be grown to profit. In America the growing of the berries for market is an important industry, Massachusetts and New Jersey being the chief centres. In America the land for growing Cranberries is flooded from Autumn to May with from 18in. to 2ft. of water. On the first of the latter month the water is drained away, and the plants soon put forth their blossoms. It is probably owing to the irrigation of the land being necessary that the profitable culture of the fruits has not been attempted on anything of a scale in England.

CRANEFLY, or **DADDY LONG-LEGS** (*Tipula oleracea*). These pests are amongst the worst against which grass-growers have to contend. They are, however, injurious to many other crops besides those noted in Vol. I. Strawberry-plants are often badly attacked; while corn and leguminous crops like Clover, Peas, and Beans suffer considerably in some seasons. For grass land, soot and lime, in the proportion of three parts of the former to one of the latter, have proved of service, and similarly in the case of Strawberries affected. In the latter case it is usual to trim the plants close, and hoe in the soot and lime. In the case of lawns, in addition to dressings of soot and lime, they should be rolled every evening towards dusk, as then thousands of insects will be destroyed as they emerge, and before they have an opportunity of depositing their eggs.

CRANIOLARIA ANNUA. A synonym of **Martynia proboscidea** (which *see*).

CRANTZIA (of Scopoli). A synonym of **Alloplectus** (which *see*).

CRANTZIA (of Vellozo). A synonym of **Centratherum** (which *see*).

CRAPE FERN. *See* **Todea.**

CRASPEDIA (from *kraspedon*, a fringe; in allusion to the form of the pappus). SYN. *Richea* (of Labillardière). ORD. *Compositæ*. A genus consisting of five species of greenhouse, silvery-silky, woolly or nearly glabrous, perennial herbs, mostly natives of Australia and New Zealand. Flower-heads yellow or whitish, few-flowered, homogamous; florets tubular, five-toothed; involucre consisting of many or few scarious bracts; receptacle very narrow. Leaves alternate or radical, entire. *C. Richea*, the only species known in gardens, is best treated as a half-hardy annual.

C. pilosa (pilose). A synonym of *C. Richea*.

C. Richea (Richea). *fl.-heads* yellow, in solitary, depressed-globular clusters ¾in. to 1in. in diameter. *l.*, radical ones ovate-oblong to lanceolate, several inches long, narrowed to a long petiole; cauline ones narrow, stem-clasping. *h.* 1ft. Australia, 1881. Plant usually woolly- or silky-white. (B. M. 5271.) SYN. *C. pilosa* (B. R. 1908).

C. R. macrocephala (large-headed). *fl.-heads* in larger clusters. Plant tall and nearly glabrous. (B. M. 3415, under the name of *C. macrocephala*.)

CRASPEDOLEPIS. A synonym of **Restio** (which *see*).

CRASSINA. A synonym of **Zinnia** (which *see*).

CRASSULA. Thick-leaf. Bentham and Hooker include the following under this genus: *Dasystemon*, *Globulea*, *Kalosanthes*, *Petrogeton*, *Septas* (of Linnæus), and *Turgosea*. Leaves opposite, rarely petiolate, often connate, fleshy, entire and cartilaginous-margined, glabrous, pubescent, or scaly. *C. coccinea*, *C. jasminea*, *C. odoratissima*, and *C. versicolor* are now referred to **Rochea,** which should not be included here. To the species described on pp. 391-2, Vol. I., the following should be added:

C. abyssinica (Abyssinian). *fl.* pure white, with an odour resembling that of Hawthorn, disposed in abundantly-produced corymbs. Habit tree-like, approaching that of *C. coccinea*, but more woody. Tropical Africa. (G. M. 1888, p. 823.)

C. aloides (Aloe-like). *fl.* pale yellow, small; scape 3ft. to 4ft. high, bearing a corymb 1½ft. across. *l.* green, fleshy, 1ft. or more in length, 2in. wide at the base. Transvaal, 1896. This species has much the appearance of an Aloe.

C. columnaris (columnar). *fl.*, pure white, in a dense, capitate cyme. *l.* fleshy, orbicular, imbricated. Stem short, erect. *h.* 3in. Allied to *C. pyramidalis*. (G. C. 1898, i., f. 23.)

C. Cooperi (Cooper's). *fl.* deep carmine, produced in abundance. Habitat not recorded, 1897.

C. hybrida albiflora (white-flowered hybrid). *fl.* white, small; corymb very many flowered. *l.* triangular, fleshy. *h.* 10in. Plant erect. An interesting hybrid between *C. jasminea* and *Rochea odoratissima*.

C. impressa (marked). *fl.* disposed in loose, dichotomously-branched corymbs; petals white at base, red above, free, elliptic-oblong; peduncles and pedicels glabrous. *l.*, radical ones crowded, somewhat rosulate, oblong, linear-lanceolate, or nearly linear; cauline ones linear, opposite; all succulent, glabrous, and, as well as the stems, more or less suffused with purple. Stems tufted, 2in. to 3½in. long. 1886. SYN. *C. Schmidti* (R. G. 1225).

C. recurva (recurved). *fl.* crimson, disposed in flat-topped cymes. *l.* greyish-green, mottled with purplish-crimson. Stems 1ft. high. Zululand, 1890. This species resembles *C. rubicunda*.

C. rhomboidea (rhomboid). *fl.* pale flesh-coloured; cymes short-stalked, terminal, few-flowered, ¾in. to 1in. across. *l.* rhomboidal, hunched above the middle, sub-acute, ¼in. to ½in. thick, glaucous, dotted. *h.* 2in. to 3in. Transvaal, 1886. Plant glabrous. Of botanical interest.

C. Schmidti (Schmidt's). A synonym of *C. impressa*.

C. Schweinfurthii (Schweinfurth's). A dwarf, tufted species, with white flowers. Abyssinia, 1892.

CRATÆGUS. One or two species formerly included here are now referred to **Photinia** and **Pyrus.** To the species and varieties described on pp. 393-4, Vol. I., the following should be added:

C. Bruanti (Bruant's). A synonym of *C. Oxyacantha semperflorens*.

C. Carrierei (Carrière's). A variety of *C. mexicana*.

C. Crus-galli pendula (pendulous). Branches slender, pendent at the extremities. There are several other varieties.

C. elliptica (elliptic). A synonym of *C. flava*.

C. ferox (fierce). A synonym of *C. horrida*.

C. grignonensis (Grignon). *fr.* yellowish-green or lemon-yellow, tinted with reddish. *l.* lanceolate. 1890.

C. horizontalis (horizontal). A synonym of *C. Crus-galli linearis*.

C. Lavallei (Lavallé's). *See* **C. mexicana Carrierei.**

C. leucophlœos (white-barked). A synonym of *C. tomentosa*.

Cratægus—*continued.*

C. mexicana Carrierei (Carrière's). *fl.* at first white, subsequently becoming flesh-coloured. Spring. *fr.* bright red, resembling cherries, persistent throughout the winter. 1883. A handsome tree, of garden origin. (G. C. 1888, iv., p. 736, f. 104, and R. H. 1883, 103, under name of *C. Carrierei.*) *C. Lavallei* is very similar to, if not identical with this.

C. Michauxii (Michaux's). A synonym of *C. flava.*

C. monogyna (one-styled). A form of *C. Oxyacantha.*

C. Oliveriana (Oliver's). A synonym of *C. melanocarpa.*

C. Oxyacantha atrofusca (very dark). *fl.* pure white, medium-sized. A very beautiful, weeping variety.

C. O. flore-pleno. Of the double-flowered variety there are three forms—*coccinea*, with scarlet-, *lucida*, with white-, and *rosea*, with rose-coloured flowers.

C. O. flore-puniceo (reddish-brown flowered). *fl.* red, single, very attractive, freely produced.

C. O. foliis-tricoloribus (three-coloured-leaved). *l.* variegated with different shades of dark red, carmine, and rose. 1886. An ornamental garden variety.

C. O. Gumperi (Gumper's). *fl.* white, bordered with pink.

C. O. integrifolia (entire-leaved). A variety having undivided leaves.

C. O. monogyna (one-styled). *fl.*, calyx lobes lanceolate, acuminate, not glandular. *fr.* almost globular, having only one style and one stone. *l.* deeply tri-quinquefid, incised-toothed. Europe, &c. There are several sub-varieties of this.

C. O. rosea-superba. There is a sweet-scented double variety called *plena.*

C. O. semperflorens (ever-flowering).* A useful garden variety, flowering throughout the summer; towards autumn plants may be seen with nearly ripe fruit, green fruit, and open flowers at the same time. SYN. *C. Bruanti.*

C. O. stricta (erect). A pyramidal variety with fastigiate branches.

C. oxyacanthoides (Oxyacanthus-like). A synonym of *C. Oxyacanthus.*

C. pentagyna (five-styled). *fl.* white, in erect, somewhat pointed corymbs; peduncles and base of calyx sparingly beset with shaggy hairs. *l.* broadly oval, divided on each side into from two to four long, pointed, toothed lobes, glabrous above, hairy on the nerves beneath. A tall, thorny bush. The earliest of all the Thorns to come into leaf. SYN. *C. pinnatifida* (R. G. 366).

C. p. major (greater).* *fl.* white, large, corymbose. *fr.* bright red, pear-shaped, ⅜in. in diameter. *l.* long-stalked, lobed, and pinnatifid. North China, 1886. An ornamental form. (G. C. n. s., xxvi., p. 621, under name of *C. pinnatifida major.*)

C. pinnatifida (pinnatifid). A synonym of *C. pentagyna.*

C. prunifolia (Prunus-leaved). A variety of *C. Crus-galli.*

C. Pyracantha crenulata (slightly crenate). A yellow-berried variety.

C. P. Lelandi (Leland's).* *fr.* bright orange-scarlet, produced when the plant is but a few inches in height. 1888.

C. P. pauciflora (few-flowered). *fl.* few in corymb. *fr.* reddish-yellow. Branches very spiny. A dwarf, tufted variety, useful for hedges or for the rockery.

C. pyrifolia is a variety of *C. tomentosa.*

C. stipulacea (large-stipuled). *fl.* white, on downy pedicels, disposed in dense corymbs. *l.* glabrous, downy on the nerves beneath; lower ones lanceolate or oblong, acute, strongly toothed at the summit; those at the tips of the branches pinnatifid, with three divergent lobes; stipules very large, persistent, slightly toothed. *h.* 3ft. to 6ft.

C. tomentosa (downy). *fl.* in broader, looser, pubescent corymbs, with a disagreeable scent, and, as well as the smaller, oblong, upright, fruit, later. *l.* thicker, without glands, densely pubescent beneath. Branches pale grey, without thorns. Otherwise like *C. coccinea.* United States, 1882. SYN. *C. leucophlœos.*

CRATERIFORM. Goblet-shaped.

CRATEROSTIGMA (from *krateros*, strong, stout, and *stigma*; in allusion to the conspicuous stigma). ORD. *Scrophularineæ.* A small genus (two or three species) of dwarf, almost stemless, stove or greenhouse perennials, natives of South and tropical Eastern Africa, and closely allied to *Torenia.* Flowers spicate, racemose, or rarely solitary: calyx tubular, five-ribbed, five-toothed; corolla tube enlarged above, the dorsal lip concave, entire or emarginate, the anterior one spreading, with three broad lobes; style somewhat funnel-shaped at apex. Leaves radical, Plantain-like, many-nerved, entire. Only one species calls for mention here. For culture, *see* **Torenia.**

C. pumilum (dwarf). The correct name of the plant described on p. 59, Vol. IV., as *Torenia auriculæfolia.* Its habitat is Abyssinia.

CRAWFURDIA. SYN. *Golowninia.* Corolla tubular-campanulate or almost funnel-shaped, the limb four- or five-lobed; stamens four or five; disk shortly five-lobed or wanting.

CREAM FRUIT TREE. *See* **Roupellia grata.**

CREAM-SPOTTED TIGER MOTH. *See* **Tiger Moths.**

CREEPING SNOWBERRY. *See* **Chiogenes.**

CREMATOMIA. A synonym of **Bourreria** (which *see*).

CRENATURE. One of the teeth of a crenate margin.

CREPIDIUM. A synonym of **Microstylis** (which *see*).

CRIMSON CLOVER. *See* **Trifolium incarnatum.**

CRIMSON FLAG. *See* **Schizostylis coccinea.**

CRINITA (of Houttuyn). A synonym of **Pavetta** (which *see*).

CRINITE. Furnished with a tuft or fringe of long, weak hairs.

CRINUM. Of this genus seventy-nine species are described by J. G. Baker, in his "Handbook of the *Amaryllideæ*"; they are broadly dispersed over the tropical and sub-tropical regions of the globe. Flowers white or reddish, few or numerous in an umbel, large, sessile or shortly pedicellate; stamens affixed to the throat. Leaves persistent, usually broad. To the species described on pp. 396-7, Vol. I., the following should be added. Except where otherwise stated, stove treatment is required:

C. abyssinicum (Abyssinian). *fl.* white, fragrant, four to six in an umbel; perianth tube slender, curved, 1½in. to 2in. long, the limb horizontal or sub-erect, 2in. to 3in. long, the segments ½in. to ⅝in. broad; peduncle 1ft. to 2ft. long. *l.* about six, bluish-green, linear, sub-erect, 1ft. long, ½in. to 1in. broad, gradually narrowed. Bulb ovoid, 3in. in diameter. Abyssinia, 1892. Greenhouse. (R. G. 1892, p. 412, f. 89.)

C. amabile augustum (august). A synonym of *C. augustum.*

C. angustifolium blandum (charming). *fl.*, perianth segments broader than in the type; filaments whitish. *l.* also broader. SYN. *C. blandum* (B. M. 2531).

C. a. confertum (clustered). *fl.* sessile; perianth segments 4in. long, a little exceeding the tube. SYN. *C confertum* (B. M. 2522).

C. anomalum (anomalous). A form of *C. asiaticum.*

C. blandum (charming). A variety of *C. angustifolium.*

C. brevifolium (short-leaved). A synonym of *C. bracteatum.*

C. Broussonetii (Broussonet's). A synonym of *C. yuccæfolium.*

C. capense. This is regarded by J. G. Baker as identical with **C. longifolium.*

C. Colensoi (Colenso's). A garden synonym of *C. Moorei.*

C. confertum (clustered). A variety of *C. angustifolium.*

C. crassipes (thick-stalked). *fl.* fifteen to twenty in an umbel; perianth tube green, curved, 3in. long, the limb sub-erect, 2½in. long, the segments white, ½in. broad, with a pink keel; pedicels 1in. to 1½in. long; peduncle compressed, less than 1ft. long, ⅜in. thick. July. *l.* lorate, bright green, sub-erect, 4in. broad. Bulb very large, conical. Tropical or sub-tropical Africa (?), 1887. Stove or intermediate.

C. cruentum Loddigesii (Loddiges'). *fl.*, perianth segments tipped dark purple; pedicels as long as the ovary.

C. declinatum (declinate). A form of *C. asiaticum.*

C. distichum (two-ranked). *fl.* usually solitary, sessile; perianth tube curved, 5in. to 6in. long, the limb horizontal, about 4in. long, the segments keeled bright red, oblong, acute, connivent, 1in. broad; stamens and style nearly reaching the tips of the segments; peduncle about 1ft. long. June. *l.* about ten, distichous, linear, firm, channelled down the face, tapering, 1ft. long. Bulb small, globose. Sierra Leone. SYN. *Amaryllis ornata* (B. M. 1253).

C. Doriæ (Doria's). *fl.* white, striped with red, scented, many in an umbel; scape short. *l.* broad, wavy at the margins. Abyssinia, 1893. Stove.

C. elegans (elegant). A variety of *C. pratense.*

C. ensifolium (ensate-leaved). A variety of *C. defixum.*

C. falcatum (sickle-shaped). A synonym of *Ammocharis falcata.*

C. firmifolium (firm-leaved). *fl.* six to eight in an umbel; perianth tube straight, 5in. to 6in. long, the segments linear, 2in. to 2½in. long; peduncle 1ft. long. *l.* narrow, lorate, firm, 3ft. long, 1½in. broad, gradually tapering, with entire margins. Madagascar, 1892.

Crinum—*continued.*

C. flaccidum (flaccid). *fl.* six to eight in an umbel; perianth tube 3in. to 4in. long, usually curved, the segments pure white, oblong-lanceolate, about as long as the tube, ⅔in. broad, acute; stamens much shorter than the segments; pedicels 1in. to 1½in. long; peduncle 1½ft. to 2ft. long, much compressed. July. *l.* linear, 1½ft. to 2ft. long, 1in. to 1½in. broad. Bulb ovoid, 3in. to 4in. in diameter, with a very short neck. New South Wales and South Australia, 1819. Greenhouse. (B. M. 2133.) SYN. *Amaryllis australasica* (B. R. 426).

C. giganteum. SYNS. *C. vanillodorum, Amaryllis ornata* (B. M. 923).

C. grandiflorum (large-flowered). A garden hybrid between *C. Careyanum* and *C. capense* (*C. longifolium*). Half-hardy.

C. Hildebrandtii (Hildebrandt's). *fl.*, perianth pure white, erect; tube 6in. to 7in. long; limb segments horizontally spreading, 2in. to 3in. long, less than ½in. broad; umbel six- to ten-flowered; peduncle ancipitous, about 1ft. long. September. *l.* eight or ten, contemporary with the flowers, lanceolate, firm, 1½ft. to 2ft. long. Bulb 2in. to 3in. in diameter; neck 6in. long. Comoro Islands. (B. M. 6709.) A variety with more numerous flowers is figured in I. H. 1886, 115.

C. humile (dwarf). *fl.* six to nine in an umbel, cernuous in bud; perianth tube greenish, 3in. long, the segments white, linear-lanceolate, spreading, 2in. long, ½in. broad; filaments bright red; rather longer than the perianth segments; pedicels short; peduncle slender, 1ft. long. October. *l.* linear, 1ft. long, spreading, sub-acute, thicker than in *C. amœnum*, pitted over the face. Bulb small, globose, greenish, with a very short neck. Tropical Asia, 1826. (B. M. 2636.)

C. insigne (remarkable). A slight variety of *C. latifolium.*

C. jemense. *fl.* pure white, in large umbels. *l.* broad, shining green. Arabia, 1892. A handsome plant.

C. Kircape. A name given to a garden hybrid between *C. Kirkii* and *C. capense (longifolium).*

C. Kunthianum (Kunth's). *fl.* white, fragrant, four or five in an umbel; perianth tube 7in. to 8in. long, the segments lanceolate, 2½in. long; peduncle 1ft. long. *l.* about twenty to a bulb, lorate, spreading, bright green, 12in. to 20in. long, 2in. to 3in. broad, undulated towards the entire margin. Bulb ovoid, 3in. in diameter, with a short neck. Colombia, 1890.

C. Laurenti (Laurent's). *fl.* white, about four in an umbel; tube 6in. long. Congo, 1897. A species very nearly allied to *C. giganteum.* Greenhouse.

C. Lesemanni (Lesemann's). A synonym of *C. Powellii*, the plant bearing this name being of the same parentage.

C. leucophyllum (white-leaved). *fl.* pinkish, fragrant, forty or fifty in a dense, centripetal umbel; perianth tube cylindrical, 3in. long, the segments linear, spreading, rather shorter than those of the tube; scape springing from below the leaves, 1ft. long. August. *l.*, produced ones about twelve or fourteen, arranged in a distichous column about 1ft. long, lanceolate, 1½ft. to 2ft. long, 5in. to 6in. broad, whitish-green, denticulate Bulb nearly 6in. in diameter. Damara-land, 1880. (B. M. 6783.)

C. lineare (linear). *fl.* five or six in an umbel; perianth tube slender, curved, 1½in. to 2½in. long, the segments tinged red outside, oblanceolate, acute, 2in. to 3in. long, ½in to ½in. broad; pedicels ½in. to ⅔in. long; peduncle slender, sub-terete, 1ft. long. September. *l.* linear, 1½ft. to 2ft. long, ½in. broad, glaucous-green, channelled down the face. Bulb small, ovoid. Cape Colony. SYNS. *Amaryllis revoluta* (B. M. 915), *A. r. gracilior* (B. M. 623).

C. Loddigesii (Loddiges'). A variety of *C. eruentum.*

C. longifolium. *C. capense* is synonymous with this species.

C. l. Farinianum (Farini's). *fl.* five or six in an umbel; perianth tube greenish, 3½in. to 4in. long, the segments pink, connivent in a narrow funnel 3in. long; scape 2ft. high. *l.* ensiform, 3ft. to 4ft. long, acuminate, glaucescent, entire. Bulb 2½in. to 3in. in diameter, narrowed into a neck 6in. long. 1887.

C. longifolium, of Roxburgh. A synonym of *C. pratense.*

C. Mackenii (Macken's). A garden synonym of *C. Moorei.*

C. Massaiana (Duc de Massa's). *fl.* white, each perianth segment having a central stripe of dull rose-colour. 1887. (I. H. 1887, 55, under the name of *Brunsvigia Massaiana.*) This "is no doubt a Crinum, nearly allied to *C. Kirkii*" (J. G. Baker).

C. moluccanum (Moluccas). A slight variety of *C. latifolium.*

C. Moorei Schmidtii (Schmidt's). A form with pure white flowers. SYN. *C. Schmidtii* (R. G. 1072).

C. M. variegatum (variegated). In this variety the leaves are striped with yellow. 1895.

C. natalense (Natal). A garden synonym of *C. Moorei.*

C. plicatum (folded). A form of *C. asiaticum.*

C. Powellii (Powell's).* *fl.* about eight in an umbel; perianth tube greenish, curved, 3in. long, the segments reddish, oblanceolate, acute, 4in. long, 1in. broad; stamens much shorter than the perianth segments; peduncle compressed, glaucous, 2ft. long. *l.* about twenty, spreading, ensiform, acuminate, bright green, 3ft. to 4ft. long, 3in. to 4in. broad low down. Bulb globose,

Crinum—*continued.*

with a short neck. A garden hybrid (of which there are several forms) between *C. longifolium* and *C. Moorei.* Hardy in the South of England.

C. P. alba (white).* A splendid white-flowered variety, with eight to fifteen blossoms in an umbel. 1893.

C. pratense (meadow-loving). *fl.* six to twelve in an umbel; perianth tube greenish, 3in. to 4in. long, at first curved, the segments white, lanceolate, nearly or quite as long as the tube, ½in. broad; filaments bright red, rather shorter than the segments; pedicels none or very short; peduncle lateral, 1ft. or more in length. June and July. *l.* six to eight to a bulb, linear, sub-erect, 1½ft. to 2ft. long, 1½in. to 2in. broad, narrowed to the point, channelled on the face. Bulb ovoid, 4in. to 5in. in diameter, with a short neck. India, 1872.

C. p. elegans (elegant). *fl.*, perianth tube 1in. shorter than the segments; peduncle decumbent. Bulb with a longer neck than in the type. SYN. *C. elegans* (B. M. 2592).

C. procerum (tall). A form of *C. asiaticum.*

C. Roozenianum (Roozen's). *fl.* white, reddish on the outside, four to twelve in an umbel; filaments red. *l.* 2½in. to 3½in. long. Jamaica, 1891. This plant is described as "near *C. americanum*, though the growth is something like that of *C. erubescens.*" (R. H. 1894, p. 120, f. 47.)

C. Sanderianum (Sander's). *fl.* sessile, borne in umbels of three or four together; perianth segments white, with a broad, conspicuous band of reddish-crimson down the centre, lanceolate, spreading-recurved. *l.* ensiform, 1ft. to 1½ft. long. Bulb globose, 2in. in diameter. Sierra Leone, 1884. A beautiful plant. (F. & P. 1884, p. 156.)

C. Schimperi (Schimper's). *fl.* few in an umbel; perianth tube reddish-green, cylindrical, 4in. long, the limb pure white, funnel-shaped, 4in. long, the lobes oblanceolate, acute; peduncle brownish, 2ft. long. July. *l.* eight to ten, linear, recurving, glabrous, 3ft. long, 2in. broad, green above, glaucous beneath. Mountains of Abyssinia, 1894. Half-hardy. (B. M. 7417; R. G. 1309.)

C. Schmidtii (Schmidt's). A form of *C. Moorei.*

C. sinicum (Chinese). A form of *C. asiaticum.*

C. speciosum (showy). A slight variety of *C. latifolium.*

C. spirale (spiral). A synonym of *Carpolyza spiralis.*

C. strictum (narrow). *fl.* about four in an umbel; perianth tube pale green, sub-erect, about 5in. long, the segments white, lanceolate, 3in. to 4in. long, ½in. broad; filaments red, 1in. shorter than the segments; pedicels none or very short; peduncle green, twice as long as the leaves. September. *l.* lorate, pale green, sub-erect, 1ft. long, 2in. to 2½in. broad. Bulb small, ovoid, without any distinct neck. South America. (B. M. 2635.)

C. sumatranum (Sumatra). *fl.* ten to twenty in an umbel; perianth tube greenish, erect, 3in. to 4in. long, the segments not tinged red outside, linear, as long as the tube; filaments bright red, much shorter than the segments; pedicels very short; peduncle much shorter than the leaves. July. *fr.* as large as a man's fist, one- to three-seeded. *l.* ensiform, sub-erect, 3in. to 4in. broad, gradually narrowed to a point, firm, dark, dull green, the edges serrulated. Bulb ovoid, as large as in *C. asiaticum.* Sumatra. (B. R. 1049.)

C. taitense (Tahiti). A synonym of *C. pedunculatum.*

C. undulatum (wavy). *fl.* four in an umbel; perianth tube greenish, 7in. to 8in. long, curved before the flower expands, the segments not purple outside, lanceolate, undulated, erecto-patent, 3in. long; filaments bright red, 2in. long; pedicels none or very short; peduncle 1ft. long. November. *l.* dark green, ensiform, firm, sub-erect, 1½ft. long, 1in. broad. Bulb small, ovoid, with a long neck. North Brazil. (H. E. F. 200.)

C. vanillodorum (Vanilla-scented). A synonym of *C. giganteum.*

C. variabile (variable). *fl.* ten to twelve in an umbel; perianth tube greenish, curved, 1½in. to 2in. long, the segments flushed red down the back, oblong, acute, 2½in. to 3½in. long; filaments red, 1in. shorter than the segments; pedicels ½in. to 1in. long; peduncle erect, compressed, 1ft. to 1½ft. long. April. *l.* ten to twelve to a bulb, linear, green, weak, 1½ft. to 2ft. long, 2in. broad. Bulb ovoid, 3in. to 4in in diameter, with a short neck. Cape Colony. SYNS. *C. v. roseum* (B. R. 1844, 9), *Amaryllis revoluta robustior* (B. R. 615).

C. v. roseum (rosy). A synonym of *C. variabile.*

C. Woodrowi (Woodrow's). *fl.* about twelve in an umbel; perianth white, having a long tube; scape 2ft. long. *l.* broad, glaucous. Bulb large, ovate, brown, with scarcely any neck. Bombay, 1897. (B. M. 7597.)

C. yuccæflorum (Yucca-flowered). *fl.* one or two in an umbel, sessile; perianth tube greenish, curved, 4in. to 5in. long, the limb horizontal, 3in. to 4in. long, the segments oblong, acute, connivent, banded red on the back; filaments 1in. shorter than the segments; peduncle slender, 1ft. long. June. *l.* ten to twelve to a bulb, multifarious, linear, firm, 1ft. to 1½ft. long, about 1in. broad. Bulb small, globose, purplish. Sierra Leone, 1785. SYNS. *C. Broussonetii* (B. M. 2121; L. B. C. 668), *C. yuccæoides, Amaryllis spectabilis* (A. B. R. 390).

Crinum—*continued.*

C. yuccæfolium (Yucca-leaved). A greenhouse plant, very similar to *C. abyssinicum*, but smaller in all its parts. Abyssinia, 1892.

C. yuccæoides (Yucca-like). A synonym of *C. yuccæflorum.*

C. zeylanicum reductum (reduced). *fl.* about four in an umbel, sessile; perianth white, with a red, central stripe on each segment; scape lateral, less than 1ft. long. *l.* ensiform, spreading, 1ft. to 1½ft. long, 1¼in. to 1¾in. broad, gradually narrowed from middle to apex, the edges not ciliated. Zanzibar, 1884.

CRIOSANTHES. A synonym of **Cypripedium** (which *see*).

CRISP, CRISPED. Curled; finely undulate, especially near the margin; *e.g.*, the leaves of garden Endive or of Savoy Cabbages.

CROCIRIS. A synonym of **Crocus** (which *see*).

CROCODILOIDES. A synonym of **Berkheya** (which *see*).

CROCOSMIA. To the species described on p. 398, Vol. I., the following varieties should be added:

C. aurea flore-pleno (double-flowered). A distinct form, with double flowers. 1893.

C. a. imperialis (imperial).* *fl.* of a brilliant fiery orange-red colour, twice as large as in the type. 1888. A grand variety.

C. a. maculata (spotted). *fl.* orange, large, having the three inner segments marked near the base with a dark reddish-brown spot. South-east Africa, 1888. (G. C. 1888, iv., pp. 407, 565, f. 80.)

CROCUS. SYN. *Crociris.* The information here given is based upon Mr. George Maw's magnificent "Monograph of the Genus *Crocus*," published in 1886. By the assistance of the following "key" to the grouping of the Crocuses in cultivation, the name of any species may be the more readily determined. The number of species described by Mr. Maw is sixty-seven: of these about seventeen are lost to cultivation, or await introduction to this country. *C. aërius*, *C. ancyrensis*, *C. Fleischeri*, *C. nevadensis*, and *C. ochroleucus* require a cold frame to bring them to perfection. *See also* pp. 398-400, Vol. I.

Division I. Involucrati.

Species with a basal spathe springing at the base of the scape from the summit of the corm.

SECTION I. FIBRO-MEMBRANACEI,

With a corm-tunic of membranous tissue, or of membranous tissue interspersed with nearly parallel fibres.

AUTUMN-FLOWERING. *asturicus, Cambessedesii, Clusii, iridiflorus, karduchorum, nudiflorus, ochroleucus, Salzmanni, Scharojani, vallicola, zonatus.*

SPRING-FLOWERING. *Imperati, Malyi, minimus, suaveolens, versicolor.*

SECTION II. RETICULATI,

With a corm-tunic of distinctly reticulated fibres.

SPRING-FLOWERING. *banaticus, corsicus, etruscus, Tommasinianus, vernus.*

AUTUMN-FLOWERING. *hadriaticus, longiflorus, medius, sativus.*

Division II. Nudiflori.

Species without a basal spathe.

SECTION I. RETICULATI,

With a corm-tunic of distinctly reticulated fibres.

AUTUMN-FLOWERING. *cancellatus.*

SPRING-FLOWERING. *ancyrensis, carpetanus, dalmaticus, gargaricus, reticulatus, Sieberi, susianus.*

SECTION II. FIBRO-MEMBRANACEI,

With a corm-tunic of membranous tissue, or of membranous tissue interspersed with nearly parallel fibres.

SPRING-FLOWERING. LILAC OR WHITE: *alatavicus, hyemalis, nevadensis.*

AUTUMN-FLOWERING. LILAC OR WHITE: *Boryi, lævigatus, Tournefortii.*

SPRING-FLOWERING. *aureus, Balansæ, Biliottii, Korolkowi, Olivieri, Suterianus, vitellinus.*

SECTION III. ANNULATI.

Basal tunic of corm separating into annuli.

SPRING-FLOWERING. *aërius, biflorus, chrysanthus, Crewei, Danfordiæ, Tauri.*

AUTUMN-FLOWERING. *pulchellus, speciosus.*

SECTION IV. INTERTEXTI.

With a corm-tunic of stranded or plaited fibres.

SPRING-FLOWERING. *Fleischeri.*

Crocus—*continued.*

C. Adami (Adam's). A variety of *C. biflorus.*

C. aërius (aërial). *fl.*, perianth tube pale lilac, 2in. long; segments bright lilac, obovate or oblong, obtuse, 1in. to 1¼in. long; throat bright yellow; proper spathe of two lanceolate, hyaline valves. Spring. *l.* but little developed at the flowering season, narrow-linear, with revolute margins and a distinct white rib down the face; basal spathe none. Corm globose, ½in. to ¾in. in diameter, the tunics brown. Asia Minor, 1835. (B. M. 6852 B; M. C. 58.)

C. algeriensis (Algeria). A synonym of *C. nevadensis.*

C. ancyrensis (Angora). *fl.*, perianth tube orange or purple, about 3in. long; throat unbearded; segments rich orange, ovate-lanceolate, ¾in. to 1in. long, ½in. broad. Spring. *l.* three or four, produced to 1ft. in length, glabrous, $\frac{1}{16}$in. broad; sheathing ones about four, ½in. to 3in. long. Corm pyriform, ¾in. broad, 1in. high. Angora, 1879. (M. C. 38.)

C. asturicus (Asturias).* *fl.*, perianth tube 4in. to 5in. long; throat violet, bearded; segments violet or purple, with a few darker lines towards the base, very variable, rarely white, 1½in. to 1¾in. long, ½in. to ¾in. broad. September to November. *l.* four or five, about 1ft. long, $\frac{1}{16}$in. broad, glabrous; sheathing ones four or five, ½in. to 2½in. long. Corm ¾in. to ¾in. broad, ½in. to ¾in. high. Asturias and Sierra de Guadarrama, North Spain. (M. C. 7.)

C. atlanticus (Atlantic). A synonym of *C. nevadensis.*

C. aureus luteus striatus (yellow, striped). *fl.* having three distinct, black stripes on the back of the outer perianth-segments. 1893.

C. Balansæ (Balansa's). *fl.*, perianth tube 2in. to 2½in. long; throat glabrous; segments orange, 1½in. long; ½in. to ¾in. broad, the outer surface of the outer ones feathered bronze or evenly suffused rich brown. March. *l.* appearing before and with the flowers, about 10in. long, $\frac{1}{16}$in. broad, ciliated on the margins of the keel and blade; sheathing ones about three, ½in. to 2½in. long. Corm pyriform, ¾in. broad and deep. Western Asia Minor. (M. C. 51.)

C. banaticus (South Hungarian).* *fl.*, perianth tube violet, 3in. long; throat white internally, unbearded; segments 1½in. long, ¾in. broad, the inner ones rich, bright purple, with darker purple markings near the summit, paler than the outer, varying to white, or variegated purple and white. March. *l.* about three, 1½ft. long, ¾in. broad, glabrous, the lateral channels wide and open; sheathing ones about four, ½in. to 3in. long. Hungary, &c. (M. C. 24.) SYN. *C. veluchensis*, of gardens (?B. M. 6197). The following are forms of this species: *albiflorus, concolor, niveus, pictus*, and *versicolor.*

C. biflorus Leichtlini (Leichtlin's). *fl.* white or pale purple, having narrow-lanceolate segments. Mardin, 1891.

C. Biliottii (A. Biliotti's). *fl.*, perianth tube about 3in. long; throat glabrous; segments rich purple, with a darker blotch at the base, about 1in. long, ½in. broad. January to March. *l.* about three, 10in. long, ¼in. broad, glabrous, the lateral channels wide and open; sheathing ones three or four, ½in. to 3in. long. Corm ½in. to ½in. broad, ½in. high. Trebizond. (M. C. 56 B.)

C. Boryi lævigatus (smooth). A synonym of *C. lævigatus.*

C. B. marathoniseus (Marathon). *fl.*, stigmas less branching than in the type, and only reaching to the level of the summit of the anthers. (M. C. 47 B, f. 4.)

C. Cambessedesii (Cambessedes'). *fl.*, perianth tube 2½in. to 3in. long; throat white internally, unbearded; segments vinous-lilac or white, ¾in. long, ½in. broad, the outer ones buff on the outside, feathered purple. September to March. *l.* two or three, 5in. to 6in. long, $\frac{1}{16}$in. broad, glabrous; sheathing ones about four, 1½in. long. Corm pyriform, about ¾in. broad and high. Balearic Islands. (M. C. 13; B. R. xxxi. 37, f. 4, under name of *C. Cambessedesianus.*)

C. cancellatus (cross-barred). *fl.*, perianth tube 4in. to 5in. long; throat yellow, unbearded; segments varying from white to light purple, self-coloured or purple-feathered, 1½in. to 1¾in. long, ½in. broad; proper spathe 12in. long. September to December. *l.* four or five, glabrous, 10in. to 12in. long, $\frac{1}{16}$in. broad, the keel prominent; sheathing ones about four, ½in. to 3in. or 4in. long. North Palestine to Armenia. (M. C. 31.)

C. c. cilicicus (Cilician). *fl.*, proper spathe shorter than in the type, completely hidden by the sheathing leaves.

C. c. Mazziaricus (Mazziari's). *fl.* white, with a bright golden-orange throat.

C. carpetanus (Toledo). *fl.*, perianth tube about 3in. long; throat white, unbearded; segments varying from delicate vinous-lilac, darker on the margins, to white, and suffused externally towards the base with bluish veins, 1in. to 1¼in. long, ¾in. broad. February to April. *l.* about four, 8in. long, $\frac{1}{16}$in. broad, semi-cylindrical, without keel or lateral channels; sheathing ones about four, ½in. to 3½in. long. Spain and Portugal, 1879. (M. C. 41.)

C. Cartwrightianus (Cartwright's). A variety of *C. sativus.*

C. chrysanthus (golden-flowered), of Herbert in B. R. xxxiii. 4, f. 1. A synonym of *C. Suterianus.*

Crocus—*continued.*

C. Clusii (Clusius'). *fl.*, perianth tube 3in. to 4in. long; throat white internally, distinctly bearded; segments light purple, darker towards the base, with no feathering, 1½in. long, ½in. broad. September to December. *l.* five or six, 9in. to 10in. long, $\frac{1}{16}$in. to $\frac{1}{12}$in. broad, glabrous, the margins bearing three prominent ridges; sheathing ones three or four, the longest 2in. to 3in. long. Corm ⅜in. to ½in. broad, about ⅜in. high. Western Spain and Portugal. (M. C. 10.)

C. corsicus (Corsican). *fl.*, perianth tube 2in. to 2½in. long; throat white or lilac inside, unbearded; segments pale purple, broadly lanceolate, about 1½in. long, ½in. broad, the outer surface of the outer ones coated buff and feathered purple. April. *l.* three or four, 8in. long, $\frac{1}{16}$in. broad, the lateral channels wide and open; sheathing ones two to four, ½in. to 2½in. long. Corm ½in. to ⅜in. broad, barely ½in. high. Corsica, 1843. (M. C. 21.) SYN. *C. insularis* (B. R. xxix. 21).

C. Crewei (Crewe's). *fl.*, perianth tube much exserted; segments white, less than 1in. long, the outer ones tinged with buff and with three to five lines of purple outside; throat yellow, glabrous; anthers dark brown. February. *l.* three or four to a tuft, as high as the flower, narrow-linear, with reflexed edges and a distinct, white, central band. Corm ovoid, ½in. in diameter; tunics rigid. Island of Sogra, 1874. (B. M. 6164; M. C. 60.)

C. dalmaticus (Dalmatian). *fl.*, perianth tube about 2in. long; throat yellow, unbearded; segments generally lilac, 1½in. long, ⅜in. to ½in. broad, the outer surface of the outer ones buff, with a few purple veins towards the base, or delicately feathered purple. February and March. *l.* three to six, 8in. to 9in. long, ⅛in. broad, glabrous, the keel convex; sheathing ones about three, ½in. to 2in. long. Corm pyriform, ½in. to ⅝in. broad and high. Dalmatia. (M. C. 34.)

C. Danfordiæ (Mrs. Danford's). *fl.*, perianth tube 2½in. long; throat unbearded; segments pale sulphur-yellow, about ⅜in. long, ⅜in. broad, the outer surface of the outer ones occasionally suffused brown. February and March. *l.* three or four, 12in. to 14in. long, $\frac{1}{16}$in. broad, ciliated on the margins of the keel and blade; sheathing ones about four, ½in. to 3in. long. Corm about ½in. broad and high. Yar-puz, Anti-Taurus, 1879. (M. C. 63.)

C. Elwesii (Elwes'). A variety of *C. sativus.*

C. estriatus (not striated). A form of *C. biflorus.*

C. etruscus (Etruscan). *fl.*, perianth tube striped lilac, 2in. to 3in. long; throat yellow; segments bright lilac-purple inside, 1in. to 1½in. long, the three outer ones having five lilac stripes down the back. March. *l.* two to six, narrow-linear, with a white, central band, the edges revolute. Corm ½in. to ⅝in. broad, rather less in height. Italy, 1877. (B. M. 6362; M. C. 22.)

C. Fleischeri (Fleischer's).* *fl.*, perianth tube about 3in. long; throat pale yellow, unbearded; segments white, linear-lanceolate, acute, 1in. to 1½in. long, barely ½in. broad, the outer surface of the outer ones and the tube veined rich purple. Early spring. *l.* four or five, 1ft. long, $\frac{1}{12}$in. to $\frac{1}{8}$in. broad, glabrous; sheathing ones about five, ½in. to 3in. or 4in. long. Corm yellow, ½in. to ⅝in. broad and high, producing bulbils or cormlets at its base. Western Asia Minor. (M. C. 66.)

C. fulvus (fulvous). A variety of *C. susianus.*

C. gargaricus (Mount Gargarus). *fl.*, perianth tube nearly 3in. long; throat unbearded; segments rich orange, unstriped, about 1½in. long, barely ½in. broad. Early spring. *l.* about three, 7in. to 8in. long, $\frac{1}{16}$in. broad, glabrous, the margins revolute, the lateral channels broad and open; sheathing ones two to four, ½in. to 2½in. long. Corm about ½in. broad, and nearly as high. Mount Gargarus. (M. C. 39.)

C. hadriaticus (Adriatic).* *fl.*, perianth tube 3in. to 4in. long; throat white or purple, bearded; segments pure white, or purple towards the base, ovate-lanceolate, 1½in. long, ⅝in. broad. October. *l.* five or six, 1½ft. long, one line broad, ciliated on the margins and keel, the lateral channels narrow, the reflected margins of the blade nearly meeting the margins of the keel; sheathing ones six or seven, ½in. to 3½in. long. Corm about 1in. broad and ⅝in. high. Albania, Ionian Islands, &c. (M. C. 30, f. 1, 2.)

C. h. chrysobelonicus (Chrysobeloni). *fl.*, throat of the perianth yellow. (M. C. 30, f. 3.)

C. Haussknechtii (Haussknecht's). A variety of *C. sativus.*

C. hyemalis (winter). *fl.*, perianth tube about 2in. long; throat yellow, unbearded; segments white, veined rich purple towards the base, about 1½in. long and ½in. broad; anthers orange. November to January. *l.* four to seven, 1½in. to 1¾in. long, ½in. broad, glabrous, the lateral channels without ridges; sheathing ones about four, ½in. to 2½in. long. Corm ½in. to ⅝in. broad and high. Palestine and Syria. (M. C. 43, f. 1-7.)

C. h. Foxii (H. Fox's). *fl.*, outer surface of the outer perianth segments freckled and suffused purple; anthers black. (M. C. 43, f. 8, 9.)

C. Imperati. The following are garden varieties: *albiflorus* (white-flowered), *atropurpureus* (dark-purple), *flore-pleno* (double-flowered), *lilacinus* (lilac), *pallidus* (pale), and *purpureus* (purple).

C. insularis (insular). A synonym of *C. corsicus.*

Crocus—*continued.*

C. karduchorum (Kurdish). *fl.*, perianth tube 2in. to 3in. long; segments vinous-lilac, 1in. to 1¼in. long, five lines broad. September and October. *l.* glabrous, dormant at the flowering time, when produced 1½in. to 2in. long, $\frac{1}{16}$in. broad, persistent till the next flowering period, when the two sets of leaves exist together; sheathing ones four or five, about 1in. long. Corm nearly spherical, ½in. to ⅝in. broad and high. Kurdistan, 1886. (M. C. 5.)

C. Korolkowi (Korolkow's). *fl.*, perianth tube brownish, 2in. long; segments bright yellow inside, oblanceolate-oblong, 1in. to 1½in. long, the three outer ones tinged with brown all over the back; spathe valves two, 1in. long. Spring. *l.* eight to twelve to a cluster, reaching to the top of the flowers, narrow-linear, with revolute margins and a distinct, white, central band down the face; basal spathe none. Corm depressed-globose, 1in. in diameter; outer tunics brown. Central Asia, 1885. (B. M. 6852 A; M. C. 56.)

C. lævigatus (smooth). *fl.*, perianth tube 3in. long; throat glabrous; segments varying from white to lilac, 1½in. to 1¾in. long, ½in. broad, the outer surface of the outer ones either self-coloured buff or more generally feathered or suffused rich purple. October to spring. *l.* four or five, appearing before the flowers, 9in. to 10in. long, $\frac{1}{16}$in. to ⅛in. broad, glabrous, the lateral channels without ridges; sheathing ones three, ½in. to 2½in. long. Corm pyriform, ⅝in. broad and high; tunic glabrous. Morea, &c. (M. C. 49.) SYN. *C. Boryi lævigatus.*

C. longiflorus (long-flowered). *fl.*, perianth tube yellow, about 4in. long; throat orange, slightly bearded; segments of a uniform, pale vinous-lilac, yellow towards the base, or externally veined or feathered purple, 1½in. long, ½in. to ⅝in. broad. October and November. *l.* about three, appearing with the flowers, 8in. to 9in. long, ⅛in. broad, the lateral channels broad and open; sheathing ones about five, ½in. to 3in. long. Corm nearly spherical, ½in. to ⅝in. in diameter. South Italy, Sicily, &c., 1843. (B. R. xxx. 3, f. 4; M. C. 28.)

C. Malyi (Maly's). *fl.*, perianth tube yellow, about 3in. long; throat orange, bearded; segments white, orange towards the throat, occasionally suffused externally with vinous-purple towards the throat, ovate-lanceolate, 1½in. to 1¾in. long. March. *l.* four or five, appearing with the flowers, 1½ft. long, ⅛in. to ¼in. broad, glabrous, the lateral channels wide and open, containing three low ridges; sheathing ones six or seven, ½in. to 4in. long. Corm oblate, ⅝in. broad, ½in. to ½in. high. Monte Vermaz. (B. M. 7590; M. C. 18.)

C. marathoniscus (Marathon). A variety of *C. Boryi.*

C. medius (intermediate). *fl.*, perianth tube 4in. to 5in. long; throat nearly white, internally veined purple, unbearded; segments bright purple, internally veined towards the base with dark purple, ovate-lanceolate, 2in. long, ⅝in. to ¾in. broad, the inner ones somewhat shorter than the outer ones. October and November. *l.* two or occasionally three, 10in. to 12in. long, $\frac{1}{16}$in. broad, the margins of keel and blade slightly ciliated, the lateral channels broad and open, containing three low ridges; sheathing ones about five, ½in. to 3in. long. Corm a little broader than high, ⅝in. in diameter under cultivation, much smaller in the wild state. Riviera, 1843. (B. R. xxxi. 37, f. 5; F. M. 20; Gn. xiv., p. 153, f. 10; M. C. 27.)

C. minimus (least). *fl.*, perianth tube 1½in. to 2in. long; throat white or lilac, unbearded; segments deep, rich purple, 1in. to 1¼in. long, ½in. broad, the outer surface of the outer ones coated buff and feathered dark purple, occasionally white or self-coloured purple. April. *l.* three or four, appearing before the flowers, 8in. to 9in. long, one line broad, glabrous; sheathing ones about three, 1in. to 2½in. long, including several scapes. Corm pyriform, fully ½in. broad and high. Corsica. An attractive little plant. (B. M. 6176; M. C. 19.)

C. minimus (least), of B. M. 2991. A synonym of *C. biflorus.*

C. mouradi (Mourad-dagh). *fl.* bright orange; style pale orange; anthers pale yellow. *l.*, sheathing ones four, the highest 5in. above the corm; proper leaves seven or eight, ½in. broad. Corm oblate, ⅝in. broad, 1in. high. Mourad-dagh, Smyrna, 1889. A vigorous grower, intermediate between *C. chrysanthus* and *C. aureus.*

C. nevadensis (Sierra Nevada). *fl.*, perianth tube 2½in. to 3in. long; throat pale yellow, bearded; segments pale lilac or white, the outer surface variously feathered or veined purple, 1in. to 1½in. long, ½in. broad. January. *l.* four or five, appearing with the flowers, 1ft. long, $\frac{1}{12}$in. to $\frac{1}{10}$in. broad, glabrous, channelled with six alternating ridges and furrows; sheathing ones about four, ⅝in. to 4in. long. Corm ⅝in. to ¾in. broad, ½in. to ⅝in. high. Spain and Algeria. (M. C. 42.) SYNS. *C. algeriensis, C. atlanticus.*

C. nubigenus (cloud-born). A form of *C. biflorus.*

C. ochroleucus (yellow and white). *fl.*, perianth tube pale buff, 3½in. long; throat orange, slightly bearded; segments pale cream-colour, suffused orange towards the base, about 1½in. long and ½in. broad. Late autumn. *l.* four to six, glabrous, appearing before the flowers, 10in. to 12in. long, nearly ½in. broad, the lateral channels wide and open; sheathing ones about six, ½in. to 2½in. long. Corm oblate, 1in. broad, ½in. high. North Palestine and Syria. (B. M. 5297; M. C. 11.)

C. Olivieri (Olivier's). *fl.*, perianth tube 1½in. to 2in. long; throat glabrous; segments bright orange, obtuse, 1in. to 1¼in.

Crocus—*continued.*

long, about ¼in. broad. Spring. *l.* three or four, appearing with the flowers, 1ft. long, ⅓in. broad, the lateral channels wide and open, the margins of the keel and blade ciliated; sheathing ones about four, ½in. to 3½in. long. Corm ½in. to ⅝in. broad and high, nearly spherical. Greece, &c. (B. M. 6031; M. C. 53.)

C. Orsinii (Orsini's). A variety of *C. sativus.*

C. Pallasii (Pallas'). A variety of *C. sativus.*

C. Salzmanni (Salzmann's).* *fl.*, perianth tube 3in. to 4in. long; throat yellowish, bearded; segments vinous-lilac, occasionally white, about 2in. long and ⅝in. broad, the outer surface of the outer ones feathered purple. Autumn. *l.* six or seven, developed before the flowers, 1ft. to 1½ft. long, about ⅓in. broad, glabrous, the keel narrow and prominent; sheathing ones three or four, ½in. to 2in. long. Corm oblate, 1in. to 1½in. broad, ⅝in. high. Tangier, Spain, &c. (B. M. 6000; M. C. 9; B. R. 4, f. 4, under name of *C. Salzmannianus.*)

C. Scharojani (Scharojan's). *fl.* orange; perianth tube 4in. to 5in. long; throat unbearded; segments lanceolate, 1½in. to 1⅝in. long, four to five lines broad, the inner ones rather shorter than the outer. July and August. *l.* three, dormant at flowering time, produced to 10in. in length, broad, glabrous, the convex keel as broad as the concave blade, the blade without the usual white band, often persistent till the ensuing flowering period; sheathing ones three or four, ½in. to 1⅝in. long. Corm small, globose or depressed-globose, ½in. broad, ⅜in. high. Circassia and Armenia. (M. C. 3; R. G. 578, f. 2, a-c.)

FIG. 279. CROCUS SPECIOSUS.

C. speciosus. Fig. 279 shows this handsome autumnal-flowering species growing in the Rock Garden at Kew.

C. suaveolens (sweetly-scented). *fl.*, perianth tube 3in. to 4in. long; throat bright orange, unbearded; segments lilac, narrow-lanceolate, acute, 1½in. long, ⅝in. broad, the outer surface of the outer ones buff, with three unbranched, purple lines. March. *l.* four or five, appearing with the flowers, 8in. to 9in. long, ⅛in. broad, the lateral channels wide and open; sheathing ones three or four, ½in. to 2½in. long. Corm oblate, ⅝in. broad, ½in. high. Rome, 1830. (B. M. 3864; M. C. 15; S. B. F. G. ser. ii. 7.)

C. susianus fulvus (fulvous). *fl.*, outer surface of the outer perianth segments suffused dull brown.

C. Suterianus (Henry Suter's). *fl.*, perianth tube 3in. long; throat unbearded; segments bright orange, fulvous towards the throat, 1in. to 1¼in. long, ½in. broad. January to March. *l.* about three, appearing with the flowers, 10in. long, $\frac{1}{16}$in. broad, the surface of the keel and margins of the blade ciliated, the lateral channels wide and open; sheathing ones about four, ½in. to 3in. long, enclosing three or four scapes. Corm pyriform, ½in. to ⅝in. broad and high. Central Asia Minor. (M. C. 52.) SYN. *C. chrysanthus* (of Herbert, in B. R. xxxiii. 4, *f.* 1).

C. Suwarrowianus (Suwarrow's). A variety of *C. vallicola.*

C. syriacus (Syrian). A form of *C. vitellinus.*

C. Tauri (Taurian). *fl.*, perianth tube scarcely exserted; segments pale purple, unstriped, 1in. to 1¼in. long; throat yellow, glabrous; anthers yellow. *l.* five or six in a tuft as high as the flowers, narrow-linear, with deflexed edges and a distinct, white, central band. Corm ⅝in. to 1in. in diameter; tunics rigid. Mountains of Cilicia and Lycia, 1892. (M. C. 61.)

C. T. melanthorus (dark-anthered). A form with black anthers. 1893.

Crocus—*continued.*

C. Tommasinianus (Tommasini's).* *fl.*, perianth tube 3in. to 3½in. long; throat white, unbearded; segments pale sapphire-lavender (said by Herbert to be occasionally marked with a darker blotch near the summit), 1in. to 1½in. long, ⅓in. to ½in. broad. March. *l.* three to five, appearing with the flowers, 9in. to 10in. long, ⅛in. broad, glabrous, the lateral channels wide and open; sheathing ones about four, ½in. to 3in. long. Corm nearly spherical, barely ½in. in diameter. Dalmatia, &c. (M. C. 25.)

C. vallicola (valley-loving). *fl.*, perianth tube buff, about 3½in. long; throat bearded; segments pale cream-colour, veined internally with five to seven purple lines, and bearing two small, orange spots towards the throat, lanceolate, 1⅜in. to 2½in. long, terminating in a fine, thread-like point; proper spathe monophyllous. August and September. *l.* four or five, 10in. to 11in. long, ⅛in. broad, glabrous, with an obscure, central, white band, the lateral channels deep; sheathing ones four to six, about 1½in. long, falling short of the proper spathe. Corm oblate, ½in. to ⅝in. broad, ⅝in. high. Caucasus, &c. (B. R. xxxiii. 16, f. 3; M. C. 2, f. 1, 4, 7, 9, 13.)

C. v. lilacinus (lilac). *fl.* much smaller than in the type; perianth segments veined with feathered, purple markings, both internally and externally. (M. C. 2, f. 6, 10, 11.)

C. v. Suwarrowianus (Suwarrow's). *fl.*, perianth throat unbearded; proper spathe diphyllous. *l.*, sheathing ones exceeding the proper spathe. September and October. (M. C. 2, f. 2, 3, 5, 8, 12, 15.)

C. veluchensis (Veluchi). A garden synonym of *C. banaticus.*

C. vernus albiflorus (white-flowered). *fl.* white, smaller than those of the type; perianth segments narrower. (M. C. 26 B, f. 6.)

C. v. leucorhynchus (white-beaked). *fl.*, perianth segments pale purple, with a deep purple flush near the white, emarginate apex. (M. C. 26 B, f. 4.)

C. v. siculus (Sicilian). *fl.* small; perianth segments whitish, with three or four purple lines on the face of each, rounded at apex. (M. C. 26 B, f. 9.)

C. vitellinus (egg-yolk-coloured). *fl.*, perianth tube pale yellow, filiform, 2in. to 3in. long; limb orange-yellow, about 1in. long, "its oblong-spathulate segments concolourous in the original *vitellinus*, striped with five feathered lines in the variety *syriacus*, and in a third form plain orange, with an obscurely lineate, brownish blotch at the base" (J. G. Baker); style much divided. November to March. *l.* five or six, glabrous, with a white, central band. Syria and Asia Minor. (B. M. 6416; M. C. 50.)

C. Weldeni (Welden's). A form of *C. biflorus.*

C. zonatus (zoned).* *fl.*, perianth tube pale buff, 2½in. to 3in. long; throat bright yellow, bearded; segments rosy-lilac, about 1½in. long, six to seven lines broad, veined internally with five to seven purple lines, and bearing on the inner surface of their base two simicircular, bright orange spots. September and October. *l.* 1ft. long, ⅛in. to $\frac{5}{16}$in. broad, with a depressed, central, white band, the lateral channels wide and open; sheathing ones five to seven, ½in. to 3in. long. Corm oblate, 1in. to 1½in. broad, ½in. to ⅝in. high. Cilician Mountains and Lebanon. (M. C. 4.)

Varieties. The following garden varieties may be recommended in addition to those found on p. 400, Vol. I.: AVALANCHE, KING OF THE BLUES, L'UNIQUE, MARGOT, NE PLUS ULTRA, QUEEN OF THE PURPLES, and WHITE PEARL.

CRŒSIA BERGMANNIANA. *See* **Rosa Insects.**

CRŒSIA HOLMIANA. *See* **Pear Insects.**

CRŒSUS SEPTENTRIONALIS. *See* **Nut Sawfly.**

CRONARTIUM RIBICOLUM. *See* **Bladder Rust.**

CROPS AND CROPPING. The advantage of annually changing Crops in the kitchen garden is manifested by a healthy and cleanly growth. With a few exceptions it will be found that a Crop following a Crop of similar character is not profitable. Leguminous Crops absorb nitrogen from the atmosphere, and the land occupied by them is suitable for Onions, &c., that enjoy such an element of plant-food. A good rule is to grow bulbous or tuberous-rooted vegetables after Crops that are not of that nature; deep-rooted plants, like Beet, Parsnips, and Carrots, could follow Celery. Broccoli, Kale, Cabbage, Cauliflower, and Brussels Sprouts should not follow each other, as they absorb much the same constituents from the soil. Mixed Cropping, such as Cauliflowers, Brussels Sprouts, Savoys, &c., ought not to be planted between Potato rows, as one Crop spoils the other. Another advantage of an interchange of Crops is that by its means many fungoid diseases are kept at bay.

CROSNES (*Stachys tuberifera*). This belongs to the genus *Stachys*; but, owing to the apparent impossibility of getting it to flower, botanists have not been able to decide on its specific name; it therefore goes by the provisional one of *tuberifera*. By the French it is known as Crosnes du Japon, and over here it has been dubbed Stachys, Spirals, and Japanese or Chinese Artichokes. The roots of this vegetable are very curious-looking (see Fig. 280), quite white, and deeply corrugated in segments, giving them very much the appearance of the larva of some insect—indeed, not at all unlike the larva of the queen-bee. The foliage of the plant is small and not at all ungraceful, and the roots are produced somewhat in the way of some *Oxalis*, in long strings and in considerable abundance.

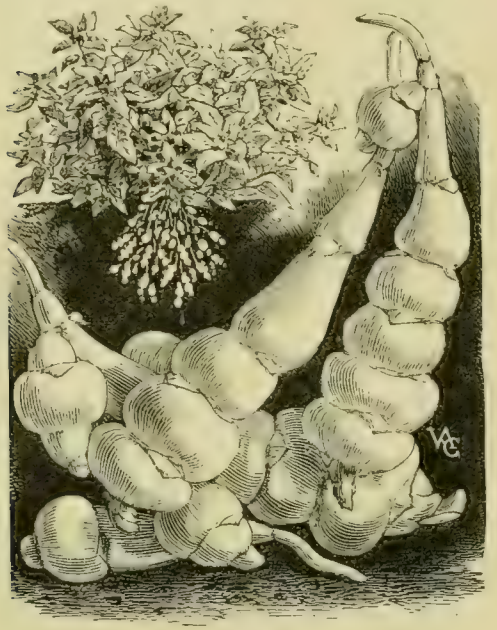

FIG. 280. CROSNES.

It should be planted in rows in any ordinary garden soil in March, the rows being about 12in. apart, and two of the roots dibbled in at about 6in. apart. With the exception of weeding, no further cultivation is required. Crosnes are perfectly hardy, and should be left in the ground, digging them up as required, as they become dark when much exposed to the air.

CROSSANDRA. To the species described on pp. 400-1, Vol. I., the following should be added:

C. flava (yellow). *fl.* yellow, disposed in a terminal, tetragonal, cone-like spike; outer bracts large, rounded, very hairy, spiny-toothed. January. *l.* glabrous, obovate-lanceolate, undulated, sinuate-pinnatifid, entire towards the apex; lower ones petiolate. Stem short, highly glabrous. Sierra Leone, 1852. (B. M. 4710.)

CROSS-FERTILISATION. *See* **Hybridising.**

CROSSYNE. Included under **Buphane** (which *see*).

CROTALARIA. To the species described on p. 402, Vol. I., the following should be added. Few of the large number introduced are now in cultivation.

C. arborescens (tree-like). A synonym of *C. capensis.*

C. benghalensis (Bengalese). A synonym of *C. juncea.*

C. capensis (Cape). *fl.* bright yellow, 1in. long, on longish pedicels; racemes terminal or opposite the leaves, lax, many-flowered. *l.*, leaflets broadly obovate, ⅜in. to 1in. long, obtuse, emarginate, acute, or mucronate; petioles ½in. to 1½in. long. *h.* 4ft. to 5ft. South Africa, 1774. A stout, greenhouse shrub. SYN. *C. arborescens.*

C. elegans (elegant). A garden name for *C. purpurea.*

C. fenestrata (window-like). A synonym of *C. juncea.*

Crotalaria—*continued.*

C. floribunda (abundant-flowered). A synonym of *Viborgia obcordata.*

C. juncea (Rush-like). *fl.* yellow; racemes loosely ten- to twenty-flowered, 1ft. long, lateral and terminal. September. *l.* rather distant, firm, linear or oblong, 1½in. to 3in. long. Branches slender, twiggy, terete. *h.* several feet. India, 1816. Stove shrub. SYNS. *C. benghalensis, C. fenestrata* (B. M. 1933).

C. longirostrata (long-beaked).* *fl.* rich yellow, with a red stripe at back; standard large, broader than long; claw ciliated; raceme erect, many-flowered. December to March. *l.* trifoliolate; leaflets oblong- or cuneate-obovate, mucronulate at apex. Mexico, 1891. A very handsome, greenhouse sub-shrub. (B. M. 7305.)

C. pulchella (pretty). A synonym of *Lebeckia cytisoides.*

C. purpurea (purple). *fl.* bright purple, ½in. long; racemes terminal, many-flowered, elongating. March to May. *l.*, leaflets ⅜in. to 1in. long, ¼in. to ½in. broad, elliptic or obovate, often drying bluish or livid, as if they contained indigo. *h.* 3ft. to 4ft. South Africa, 1790. A highly ornamental, much-branched, greenhouse shrub. (B. M. 1913.) SYN. *C. elegans* (of gardens).

C. semperflorens (ever-flowering). *fl.* bright yellow, ½in. to ⅝in. long; racemes lateral and terminal, not panicled. Spring. *l.* oblong, rounded at base, acute or obtuse, 2in. to 4in. long, green and glabrous above, pale and downy beneath; stipules leaf-like. Branches terete. India, &c. 1816. Greenhouse shrub.

CROTON BUG OF AMERICA. This is the name applied to a most destructive species of Cockroach, abundant in America and elsewhere, and known scientifically as *Phyllodromia germanica.*

CROWN. *See* **Corona.**

CROWN BEARD. *See* **Verbesina.**

CRUCIANELLA. About twenty-six species, natives of the Mediterranean region and Western Asia, are included in this genus. To those described on p. 402, Vol. I., the following should be added:

C. angustifolia (narrow-leaved). *fl.* whitish, spicate, four-parted; corolla slender; spike linear, quadrifarious, imbricated, somewhat interrupted at base. June and July. *l.* in whorls of six, linear, acute, scabrous on the margins. Plant erect. *h.* 6in. to 8in. Asia Minor, 1816. Annual. (S. E. B. 109.)

C. stylosa (prominent-styled). A synonym of *Phuopsis stylosa.*

CRUIKSHANKSIA (of Hooker). A synonym of **Balbisia** (which *see*).

CRUSEA (named in honour of Dr. G. Cruse, an authority on the Cape *Rubiaceæ*). ORD. *Rubiaceæ.* A genus embracing about ten species of stove, erect or ascending herbs, natives of Mexico and Central America. Flowers pink, mediocre, in a head with four involucral bracts. Leaves opposite, ovate or lanceolate, nerved. *C. rubra* (B. M. 1558, under name of *Spermacoce strigosa*) has been introduced, but is perhaps not now in cultivation.

CRYOSOPHILA, or **CRYSOPHILA.** Included under **Copernicia** (which *see*).

CRYPTANTHUS. SYN. *Pholidophyllum.* According to J. G. Baker, this genus now embraces about a dozen species, natives of Brazil and Guiana. Flowers white, arranged in a head in the axils of the inner leaves; sepals united in a campanulate tube just above the ovary, the segments not mucronate; petals three or four times as long as the calyx, widely spreading; stamens inserted on the corolla; anthers small. Leaves many in a rosette, spreading, with stolons in the axils of the outer ones. Only a few of the species are in cultivation. To those described on p. 402, Vol. I., the following should be added:

C. Beuckeri (Beucker's). *fl.* white, in a small head. *l.* disposed in an open rosette, petiolate, elliptic, acute or acuminate, light reddish, with numerous transverse, green, irregular lines or blotches, the margins spinulose. South Brazil, 1883. A remarkable, dwarf Bromeliad. (B. H. 1881, p. 342, t. 1.)

C. Morrenianus (Morren's). A synonym of *Distiacanthus Morrenianus.*

C. undulatus (wavy). The correct name of *C. acaulis.* The form *purpureus* (Ref. B. 237) has leaves tinged with reddish-brown.

C. zonatus (zoned). *fl.* in a small tuft in the centre of the rosette; petals white, oblanceolate, 1in. long. *l.* ten to fifteen in a short rosette, oblong-lanceolate, 6in. to 9in. long, 1½in. broad, thinly white-lepidote on the back, with small and close marginal prickles. Brazil, 1842. SYNS. *Pholidophyllum zonatum, Tillandsia zonata* and *T. zebrina* (of gardens).

C. z. fuscus (dark). *l.* brown instead of green.

CRYPTARRHENA (from *kryptos*, hidden, and *arrhen*, a male; in reference to the concealed anthers). SYNS. *Clynhymenia*, *Orchidofunckia*. ORD. *Orchideæ*. A genus embracing only a couple of species of stove, epiphytal Orchids, with small, greenish-yellow flowers; one is found in the West Indies and West and Central America, and the other in Surinam. *C. lunata* (B. R. 153) is in cultivation at Kew, but is of little horticultural interest.

CRYPTOCAMPUS ANGUSTUS. *See* **Salix.**

CRYPTOCARPUS (from *kryptos*, hidden, and *karpos*, fruit; the fruit is included within the connivent calyx). ORD. *Nyctagineæ*. A small genus (two species) of slightly fleshy, prostrate or somewhat climbing, stove or greenhouse shrubs; one is found on the Mexican mountains, and the other on the sea-coasts of tropical South America. Flowers small, cymose, hermaphrodite. Leaves alternate, exstipulate, entire. *C. globosus* (SYN. *Salpianthus purpurascens*) has been introduced, but is probably not now in cultivation.

CRYPTOCHILUS. Both species are natives of the Himalayas. Flowers closely set, in distichous spikes, shorter than their persistent bracts; sepals connate in an equally three-lobed, gibbous, five-toothed tube; petals narrow; lip included, adnate to the foot of the column, narrow, erect; pollinia eight. Pseudo-bulbs crowded, one- or two-leaved. To the species described on p. 402, Vol. I., the following should be added:

Cryptochilus—*continued.*

C. lutea (yellow). *fl.* pale yellow, sub-globose; sepals obtuse; petals and lip lanceolate; spike 2in. to 4in. long; scape 2in. to 4in. long, rather slender. Leaves one or two, 3in. to 5in. long, linear-lanceolate, acute, petiolate or nearly sessile. Pseudo-bulbs oblong. 1882.

CRYPTOCORYNE. SYN. *Myrioblastus*. This genus embraces about twenty-five species, natives of tropical Asia and the Malayan Archipelago. Flowers on a very slender spadix, the males and females very distant; spathe tube short or elongated, the lamina straight, folded or twisted. Leaves oblong- or linear-lanceolate or ovate.

FIG. 231. CRYPTOMERIA JAPONICA.

CRYPTOGAM, CRYPTOGAMIA. A Cryptogam is a plant of the class *Cryptogamia*, which is the last class in the Linnean Sexual System, and comprises those plants having no stamens or pistils, and therefore no proper flowers; it includes Ferns, Mosses, Algæ, Lichens, and Fungi.

CRYPTOGLOTTIS. A synonym of **Podochilus** (which *see*).

CRYPTOGRAMME. The Mountain Parsley Fern is essentially a deciduous plant, losing its fronds about the end of October and starting into growth again about the beginning of May. Its fertile fronds, considerably longer than the others, and produced as a second crop of foliage later in the season, are greatly appreciated for bouquets and button-holes. Their spores ripen and scatter themselves, in their native state, about September, after which the fronds soon die down, the barren ones remaining on the plants rather longer than the others.

Although usually found growing wild in exposed situations, the Mountain Parsley Fern delights in a cool, moist, and shady spot, and is especially adapted for a quiet nook in a rockery, where it should be planted in a well-drained place and in a mixture of loam and peat in about equal parts, with the addition of bricks broken into small pieces; but care should be taken that the compost is free from lime, which is highly injurious to the very minute fibrous rootlets. It may be propagated by seedlings, but this is a slow and tedious process; the more so that it is readily increased by the division of the crowns in the spring months, just before growth commences. This little gem also grows luxuriantly in a cold frame, or for two or three years in the greenhouse, or under the shade of vines, where, however, it seldom lasts any longer. The plants should always be well established in pots before being turned out into the border or on the rockery.

CRYPTOLOBUS. The species formerly classed under this name are now referred to **Amphicarpæa** and **Voandzeia** (which *see*).

CRYPTOMERIA. This genus is monotypic, *C. elegans* being a variety of *C. japonica*, which is well shown in Fig. 281. To the varieties described on p. 404, Vol. I., the following should be added:

C. japonica araucaroides (Araucaria-like). *l.* dark bluish-green, thickly disposed, but regularly arranged, imparting a very dense appearance. Japan, 1885. SYN. *C. j. lycopodioides.*

C. j. compacta (compact). This forms a compact, regular pyramid. Japan, 1885.

C. j. lycopodioides (Lycopod-like). A synonym of *C. j. araucaroides.*

C. j. Sandersii (Sanders'). A variety of dense habit.

Other varieties are *nigricans*, *pungens*, and *rubiginosa.*

CRYPTOPHORANTHUS (from *kryptos*, hidden, *phoreo*, to bear, and *anthos*, a blossom; in allusion to the petals, lip, &c., being concealed within an almost closed flower, the only opening into which is by a pair of small "windows" at the side). Window-bearing Orchid. ORD. *Orchideæ*. A curious genus, with the habit of *Pleurothallis* (section *Aggregatæ*), but differing from that genus in the sepals being united into a short tube at the base and again united at the apex—the only way into the flower being by the small, window-like openings, one on either side. From *Masdevallia* the genus differs in habit, as also in the characters just given. Eight species are known; they are stove Orchids, ranging over an area from the West Indies to the Andes and Brazil. The following species are now included here, the specific names remaining unchanged: *Masdevallia Dayana*, *M. gracilenta*, *M. hypodiscus*, and *Pleurothallis atropurpurea*. For culture, *see* **Pleurothallis.**

C. maculatus (spotted). *fl.* yellow, densely spotted crimson, numerous, ¼in. long, obovoid, obtuse, pubescent, situated at the base of the leaf on the very short stem (so short that the flowers actually lie on the soil). *l.* elliptic, obtuse, very fleshy, with numerous purple spots or small blotches on the upper surface, 1¼in. to 2¼in. long, ⅜in. to 1¼in. broad, the apex minutely tridenticulate. Probably Brazilian. A remarkable little plant. SYN. *Pleurothallis maculata.*

C. minutus (minute). *fl.* deep maroon-purple, large for the size of the plant. *l.* orbicular, apiculate, five lines long. Stems very short or wanting. *h.* not much exceeding ¼in. Habitat unknown, 1895. A very minute species.

C. oblongifolius (oblong-leaved). *fl.* dull yellow, veined with maroon-purple, pendulous; sepals nearly or quite 1in. long; petals ¼in. long; peduncles ⅜in. long, erect. *l.* elliptic-oblong, 1½in. to 3in. long. Stems terete, 1½in. to 2in. long, tubular-infundibular. Andes of South America, 1895.

C. sarcophyllus is in the Kew Collection, but is not in general cultivation.

CRYPTOSACCUS. A synonym of **Leiochilus** (which *see*).

CRYPTOSANUS. A synonym of **Leiochilus** (which *see*).

CRYPTOSTACHYS. A synonym of **Sporobolus** (which *see*).

CRYPTOSTEMMA. SYN. *Cynotis. Microstephium* is included in this genus.

CRYPTOSTYLIS (from *kryptos*, hidden, and *stylos*, a pillar, a style; in allusion to the concealed style). The generic description is given in the body of this work under Blume's name, **Zosterostylis** (which *see*).

C. longifolia (long-leaved). *fl.* three to eight, rather distant, upwards of 1in. broad; sepals yellowish-green, narrow; petals the same colour, shorter; lip red, with reddish-brown markings, pointing upwards, the short style hidden in the cucullate base (hence the generic name). *l.* solitary, lanceolate, on long stalks. *h.* 1ft. to 2ft. Tasmania, 1885. Greenhouse. (G. C. n. s., xxiii., p. 275, f. 53.)

CRYSOPHILA, or **CRYOSOPHILA.** Included under **Copernicia** (which *see*).

CUBÆA. A synonym of **Tachigalia** (which *see*).

CUBAN LILY. *See* **Scilla peruviana.**

CUBEBA. Included under **Piper** (which *see*).

CUCIFERA. A synonym of **Hyphæne** (which *see*).

CUCUBALUS (altered from *Cacobolus*, which is derived from *kakos*, bad, and *bolus*, a shoot; in allusion to the plant being destructive to the soil). ORD. *Caryophylleæ*. A monotypic genus. The species, *A. baccifer*, is a diffuse, climbing, hardy herb, native of Europe and Asia; it is of no horticultural value. Many plants formerly included hereunder are now referred to **Silene.**

CUCULLARIA. A synonym of **Vochysia** (which *see*).

CUCUMBER. *Sorts:* Improved Telegraph, Lockie's Perfection, Purley Park Hero, Cardiff Castle, Monarch, and All the Year Round, which last is one of the very best to grow in the winter. If very long Cucumbers are desired, Marquis of Lorne and Daniels' Duke of Edinburgh will prove satisfactory, both varieties growing some 30in., and of good form. For outside cultivation in summer, the Ridge varieties are the only sorts suitable, the best being Bedfordshire Surprise, Long Prickly, Short Prickly, and Stockwood.

CUCUMBER, BITTER. *See* **Citrullus Colocynthis.**

CUCUMBER-TREE. In addition to the species mentioned on p. 406, Vol. I., this name is applied to **Averrhoa Bilimbi** (which *see*).

CUCUMIS. This genus embraces about twenty-five species, mostly found in tropical Africa and Asia, a few being indigenous in Australia and America. To those described on pp. 406-7, Vol. I., the following should be added:

C. Chate (Chate). A form of *C. Melo.*

C. Dudaim (Dudaim). Canary Melon; Scented Cucumber. *fr.* orange-yellow, spotted or barred with red at maturity, spherical or ovoid, edible, having an agreeable odour. August to October. Persia. This is a form of *C. Melo.* (F. d. S. 1474.)

C. flexuosus (bending). A form of *C. Melo.*

C. Melo Chate (Chate). Egyptian Cucumber. *fl.* small, shortly pedunculate. *fr.* elliptic, attenuated to both base and apex, pilose. *l.* petiolate, rounded, obtuse, denticulate. Stem obtusely five-angled. Native country uncertain. Plant very villous.

C. M. flexuosus (bending). *fl.* fascicled in the axils; calyx very pilose. *fr.* white or yellow, elongated, cylindrical-club-shaped, sulcate, flexuous. *l.* cordate-ovate, somewhat lobed, petiolate. Stem flexuous, bearing tendrils. East Indies (?).

C. Sacleuxii (Sacleux'). *fr.* dark green, with lighter green stripes, ovoid, 3in. to 4in. long. *l.* roundish-reniform, lobed, rough and greyish-green on both sides. Zanzibar, 1890. An ornamental stove Cucumber, the fruits of which can be used for pickling.

C. Vilmorini (Vilmorin's). *fr.* canary-yellow, armed with soft spines, produced in great abundance. *l.* cut. Origin not recorded, 1894.

CUCURBITA. Pompion. The half-dozen species of this genus are distributed over the warmer parts of Asia, Africa, and America. To the species and varieties described on pp. 407-8, Vol. I., the following should be added:

C. Andreana (André's). *fl.* about half as large as those of the common Pumpkin (*C. Pepo*). *fr.* marked with white and yellow on a green ground, obovoid. *l.* large, marbled with white. Stems long, rooting at the nodes. Uruguay, 1890. Greenhouse. (R. H. 1896, p. 8, f. 1.)

C. ficifolia (Ficus-leaved). A very curious species, with round fruits somewhat resembling a Water-Melon, and climbing stems; it is very useful for large trellises. SYN. *C. melanosperma.*

C. f. mexicana (Mexican). This variety has seeds twice the size of those of the type. Mexico, 1890. Half-hardy.

C. maxima sylvestris (sylvan). *fr.* as large as a man's head. This is "supposed to be the origin of all the large-fruited Gourds in cultivation. The native country of *C. maxima* was unknown, but the present plant has been found wild in the Himalayan region." 1893. (Kew Bulletin, 1894, App. II.)

C. melanosperma (dark-seeded). A synonym of *C. ficifolia.*

C. mexicana (Mexican). A variety of *C. ficifolia.*

CUDRANIA (from the Malayan name, *Cudrang*, given to a green dye yielded by this tree). SYN. *Cudranus.* ORD. *Urticaceæ*. A small genus (three or four species) of stove, greenhouse, or hardy shrubs or small trees, usually spinous, erect or climbing, natives of Asia, Australia, and New Caledonia. Flowers dicœcious, in small, naked, globose heads. Leaves alternate, quite entire, penniveined; stipules lateral, small. For culture of the only species introduced, *see* **Morus.**

C. triloba (three-lobed). The correct name of *Maclura tricuspidata.*

CUDRANUS. A synonym of **Cudrania** (which *see*).

CULCASIA. Six or eight species, all tropical American, are comprised in this genus. Spathe small, erect; peduncles axillary, solitary, or several and fastigiate. Leaves spirally inserted.

CULEN. *See* **Psoralea glandulosa.**

CULLUMBINE, or **COLUMBINE.** *See* **Aquilegia.**

CULLUMIA (named in honour of Sir T. G. Cullum, Bart., a Norfolk botanist). ORD. *Compositæ*. A genus embracing about fourteen species of greenhouse, small shrubs or under-shrubs, all South African, allied to *Gazania*. Flower-heads yellow, terminal, solitary. Leaves alternate, sessile or decurrent, margined with cilia. *C. ciliaris* (B. M. 2095; B. R. 384) and *C. pectinata* have been introduced, but are probably not now in cultivation.

CUNCEA. A synonym of **Knoxia** (which *see*).

CUNDURANGO. *See* **Marsdenia Cundurango.**

CUNINA. A synonym of **Nertera** (which *see*).

CUNNINGHAMIA. SYNS. *Belis, Raxopitys.* This tree, which is also found in Japan, is closely allied to *Araucaria.*

CUNONIA (of Miller). A synonym of **Antholyza** (which *see*).

CUNONIEÆ. A tribe of **Saxifrageæ** (which *see*).

CUP (p. 409, Vol. I.). This term is also botanically applied to a concave involucre enclosing a nut, as in the Acorn. *See* **Cupula.**

CUPAMENI. A synonym of **Acalypha** (which *see*).

CUPANIA. This is a rather large, tropical genus, widely distributed. To the species described on p. 409, Vol. I., the following should be added:

C. Cunninghamii (Cunningham's). A synonym of *Diploglottis Cunninghamii.*

C. elegans (elegant). This is described as "a species with light and graceful leaves, undulated and toothed at the edges." Habitat not recorded, 1893.

C. grandidens (large-toothed). *l.* impari-pinnate; leaflets nine, oblong, acuminate, sinuately lobed, 3in. to 4in. long. Stems downy. Zanzibar, 1884.

CUPHEA. Including *Melvilla.* About ninety species, natives of tropical and subtropical America, are included in this genus. To those described on p. 409, Vol. I., the following should be added:

C. Commersoniana (Commerson's). *fl.*, calyx thick and, as well as the pedicels, glandular-hairy, the dorsal lobe broader than the rest; petals obovate. *l.* sub-sessile, cuneate, ovate-lanceolate, or narrow-lanceolate. Stems 6in. to 18in. long, woody below. Brazil, 1834.

C. cordata (heart-shaped). *fl.* scarlet; calyx and peduncle glutinous; petals six, the two upper ones large and nearly round, the four lower ones small. June. *l.*, lower ones cordate, acute, sub-coriaceous; upper ones oblong. Stems sub-shrubby; branchlets glutinous. *h.* 1½ft. Peru, 1842. Evergreen. (B. M. 4203; F. d. S. ii. 7.)

C. eminens (conspicuous). A synonym of *C. micropetala.*

C. ignea alba (white). A variety with white flowers. 1843.

C. Llavea (Llavea). *fl.* purple, with two large, obovate petals (the rest abortive); pedicels erect. June. *l.* sub-sessile, ovate-lanceolate, strigose. Stems numerous, hispid. Mountains of Mexico. 1830 and 1891. (B. R. 1386.)

C. Llayæ. A misprint in several publications for *C. Llavea.*

C. micropetala (small-petaled). *fl.* supra-axillary, secund; calyx scarlet, yellowish at apex, twelve-toothed; petals white; filaments red. July. *l.* oblong-lanceolate, acute at both ends, rigid, scabrous. Stems shrubby, much-branched. *h.* 1ft. Mexico, 1824.

C. pubiflora (downy-flowered). A synonym of *C. cyanea.*

C. strigulosa (slightly strigose). *fl.* violet, interpetiolar, alternate; petals six, sub-equal; stamens eleven. June to October. *l.* ovate-oblong, acute, viscous, glabrous above, scabrous-strigose beneath. Branches and calyx viscid-hispidulous. *h.* 1½ft. Andes. Shrub. (P. M. B. xi. 241.)

C. verticillata (whorled). *fl.* violet, solitary or in pairs, alternate, extra-axillary; calyx pilose-hairy, ten- to sixteen-toothed, coloured; petals five to eight, unequal. *l.* three or four in a whorl, sub-sessile, oblong, slightly acute, somewhat rounded at base, scabrous-strigulose above, pilose beneath. Branches pilose-hairy. Peru. Stove perennial. (F. d. S. vi. 510.)

CUPIA. This is for the most part synonymous with **Randia** (which *see*).

CUPRESPINNATA. A synonym of **Taxodium** (which *see*).

CUPRESSTELLATA. A synonym of **Fitzroya** (which *see*).

CUPRESSUS. About a dozen distinct species, natives of temperate Asia, South-eastern Europe, North America, and Mexico, are included in this genus, according to the authors of the "Genera Plantarum." To those described on pp. 409-10, Vol. I., the following should be added. *See also* **Chamæcyparis.**

C. arizonica (Arizona). A variety of *C. Benthami.*

C. Benthami (Bentham's). *l.* opposite, ovate, acute, imbricated, keel-shaped at back, with a hollow band in the centre, and, as well as the branchlets, dark green and glaucous when young. *cones* globular, nearly ¾in. in diameter. Branches dense, flat, spreading; branchlets four-sided, slender, mostly curved and forked. *h.* 50ft. to 60ft. Mountains of Mexico and Guatemala

FIG. 282. CUPRESSUS LAWSONIANA.

Half-hardy. SYN. *C. thurifera. C. arizonica* is a variety of this species.

C. Goveniana compacta (compact). A variety differing from the type in its dense, compact, pyramidal habit. 1896. (R. H. 1896, p. 8, f. 1.)

C. guadelupensis (Guadeloupe). A variety of *C. macrocarpa.*

C. Hartwegii is synonymous with *C. macrocarpa.*

C. Lawsoniana (Lawson's). The correct name of *Chamæcyparis Lawsoniana*, according to Dr. Masters. See Fig. 282.

C. Lindleii (Lindley's). The correct name of *C. Knightiana.*

C. macrocarpa Crippsii (Cripps'). *l.* small, open, erecto-patent, rigid, very acute, spiny-pointed, silvery when young. Branches stout, stiff, short, very compact; branchlets dense, silvery-tipped when young. A fine variety.

Cupressus—*continued.*

C. m. fastigiata (pyramidal). A variety of pyramidal habit.

C. m. flagelliformis (whip-like). Branchlets light glaucous-green, long, less divided than in the type.

C. m. guadeloupensis (Guadeloupe). This variety differs from the type principally in the glaucous colour of its leaves. 1895.

C. m. lutea (yellow). *l.* suffused with pale golden-yellow, very small. Branches short. 1893. An elegant, erect variety.

C. m. variegata (variegated). Branchlets partly golden.

C. sempervirens. Other varieties are: *fastigiata* (pyramidal), *flagelliformis* (whip-like), *monstrosa* (a tall variety), *retrofracta* (bent back), *thuiæfolia* (Thuya-leaved), and *variegata* (variegated).

C. thurifera (Frankincense-bearing). A synonym of *C. Benthami.*

C. Thyoides (Thuya-like). A synonym of *Chamæcyparis sphæroidea.*

C. torulosa majestica (majestic). A hardier and much more robust plant than the type, being larger in all its parts.

CURCULIGO. SYNS. *Empodium, Fabricia* (of Thunberg), *Forbesia.* This genus comprises about a dozen species of stove perennials, natives of tropical Asia, Australia, tropical and South Africa, and tropical America. Flowers spicate or racemose; perianth six-parted, the segments sub-equal, spreading; stamens six, affixed at the base of the segments; whole inflorescence frequently villous. Fruit more or less succulent. Leaves radical, often long-lanceolate, plicate-veined, sometimes very large. To the species and varieties described on p. 410, Vol. I., the following should be added:

C. densa (dense). *l.* oblong-ovate, acute, plicate, dark green, with a silvery lustre. India, 1885. A pretty, decorative plant, of dwarf habit.

CURCUMA. SYNS. *Erndlia, Stissera.* The species extend from tropical America to tropical Australia and the South Pacific Islands. To those described on p. 411, Vol. I., the following should be added:

C. Amada (Amada). *fl.* about 1in. long; corolla whitish, the lip pale yellow; spikes 3in. to 6in. long; bracts about 1in. long. Autumn. *l.* oblong-lanceolate, 1ft. to 1½ft. long; petioles as long as the blades; leafy tuft 2ft. to 3ft. across. Rootstock large, ovoid. India, &c., 1819.

C. aromatica (aromatic). *fl.* yellow, shorter than the bracts; corolla tube 1in. long; spike (with peduncle) 1ft. long; bracts ovate, pale green, 1½in. to 2in. long. April to June. *l.* 3ft. to 4ft. long, oblong, caudate, deltoid at base, plain or variegated with light and darker green above, pubescent beneath. Rootstock biennial; tubers sessile, aromatic. India, 1804.

C. Bakeriana (Baker's). *fl.* orange-coloured, somewhat larger than in *C. australasica* (which this species resembles); corolla-lobes ovate-oblong, shorter than the lip; spike scarcely 3in. long; bracts pale rose. *l.* distichous, oblong-lanceolate. Tuber 3in. to 3½in. long. *h.* 2ft. Islands near New Guinea, 1892.

C. cordata is identical with *C. petiolata.*

C. ferruginea (rusty). *fl.* red, few, large; fertile bracts tinged with reddish-brown, those of the coma few, bright red. Spring. *l.* oblong, 1ft. to 1½ft. long, 5in. to 6in. broad, with a faint reddish-brown cloud down the centre. Rootstock large; tubers sessile, yellow, very fragrant inside. India, 1819.

C. latifolia (broad-leaved). *fl.* pale yellow, rather shorter than the bracts; spike 6in. to 8in. long; bracts green, ovate, 1½in. long, those of the coma bright red. Spring. *l.* oblong, 3ft. to 4ft. long, clouded with purple down the middle, pubescent beneath. Rootstock large. India, 1820.

C. Leopoldi (Leopold's). *l.* lanceolate, pale green, striped with creamy-white. 1884. An attractive plant, of distinct character, growing in clumps, and resembling a Musa in habit.

C. neilgherrensis (Neilgherries). *fl.* bright yellow, 1in. long; lip deflexed, emarginate; spikes 2in. to 4in. long; bracts pale yellowish-green, 1in. to 1½in. long. Spring. *l.* lanceolate, pale green, 1ft. long including the short petiole. Malabar, &c. Plant dwarf.

C. rubescens (reddish). The correct name of *C. rubricaulis.*

CURD. A gardener's name for the head of a Cauliflower or Broccolo.

CURL BRUSH BEAN. *See* **Pithecolobium.**

CURLED. *See* **Crisp.**

CURRANT APHIDES (*Myzus Ribis* and *Rhopalosiphum ribis*). *See* **Aphides.**

CURRANT-BUD MITE (*Phytoptus ribis*), or Black Currant Gall Mite, is responsible for the condition of the bushes known as "Big Bud." It has hitherto baffled all the most experienced entomologists to cope with its attacks.

Currant-Bud Mite—*continued.*

Black Currants only are infested, and the terminal buds are usually oftenest selected. Once the creatures are inside they cause (by the irritation set up) the buds to swell abnormally (see Fig. 283), and such buds may easily be detected in late autumn. Here again insecticides are of very little avail, and hand-picking the galled buds is the most practical remedy. Still, if the trees could be sprayed during July with Kerosene Emulsion, some good might be done.

FIG. 283. CURRANT SHOOT, SHOWING ABNORMAL BUDS DUE TO CURRANT-BUD MITE.

CURRANT CLEAR-WING MOTH or **CURRANT BORER** (*Sesia tipuliformis*). On account of the absence of scales from the wings this insect (Fig. 284) is seldom taken for a Moth. Under this heading in Vol. I., as well as under **Sesia** (Vol. III.), both the perfect insect and its destructive caterpillar have been described. It is one of those pests against which the cultivator is almost powerless. In fact, the only thing to be done is to remove all dead and dying shoots and burn them.

CURRANTS. Nearly all the pests infesting the foliage may be easily eradicated with carbolic soft soap. Dissolve 2oz. in each gallon of hot water, and spray both sides of the foliage with the liquid warm. The application of such insecticides warm is most important, as the effect is far more deadly, and usually means all the difference between success and failure in coping with these foes. A far more difficult enemy to combat is the Currant-Bud Mite (*Phytoptus ribis*), dealt with under that heading.

Varieties. To the list given in Vol. I. the following should be added:

Black. CARTER'S CHAMPION, very large and deep black; the bunches are also large; a fine variety for exhibition, or for dessert.

Red. COMET, very large in bunch and berry, and of the brightest red; a great cropper; but there is a doubt about this being distinct from LA VERSAILLES. LA CONSTANTE, a large deep red, with good bunches, which are freely produced; valuable for its lateness and the time the fruit will hang on the bushes. LA VERSAILLES, a large and nice-flavoured variety, with good cropping qualities, but not a good grower in all gardens.

White. WHITE DUTCH CUT-LEAVED, bunches and berries of the largest size, of sweet and good flavour; an abundant bearer.

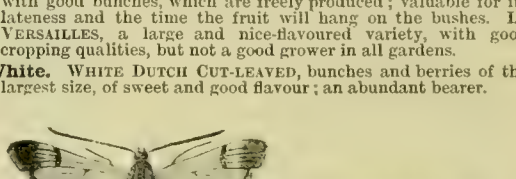

FIG. 284. CURRANT CLEAR-WING MOTH.—PERFECT INSECT AND CATERPILLAR (both magnified.)

CURRANT SCALE (*Pulvinaria ribesiæ*). Of late years Currant bushes in many parts of England have been attacked by this distinctive species of Scale, which has probably been introduced from the Continent, where it is abundant, especially in France. Its chief characteristic is an exudation of white, cottony matter, which contains the eggs and the newly-hatched Scales. The pest cannot be

Currant Scale—*continued.*

taken for anything else, and it would therefore serve no purpose to describe the Scale itself. This insect affects all varieties of Currants, and its presence is most undesirable. Remedial measures should be taken as soon as possible, weak Kerosene Emulsion being one of the best insecticides to spray on for Scale of any kind.

CURRANT-SHOOT MOTH (*Incurvaria capitella*). This is another of the small Moths (*Tineæ*) whose larvæ injure fruit and other crops. As the common name indicates, the Currants in the present case are laid under contribution, though so far no one has found the pests upon the White varieties. At one time it was thought that only Red Currants were infested, but of recent years entomologists have found the minute caterpillars in large numbers on Black Currant bushes. The species under notice is a very near relative of the Moth *Lampronia rubiella*, found upon the Raspberries. The first indication that the bushes are infested is shown towards the end of spring, and consists in a withering of the young shoots, caused by the persistent attacks of the larvæ on the pith. If such shoots are removed, it will be found that they contain the larvæ of this minute Moth.

The perfect insects are on the wing at the latter part of May. They are very small (about ⅛in. in wing expanse), and therefore readily escape notice. They are brownish, and usually have a purplish sheen, the somewhat sombre colouring being relieved by a pale yellow marking on each wing near the inner margin, and beyond are two conspicuous yellow spots. The hind-wings are greyish. Having paired, the female seeks a place to deposit her eggs. This she does within the fruits, these being pierced by means of an appendage with which she is provided. The eggs hatch out, and the young larvæ for a time feed on the seeds, each fruit containing either one or two of the little pests. Even at this point there are indications of the attack of the insect, as the berries colour prematurely. If examined they will usually be found to contain the little grubs. They do not feed on the seeds after the end of June, but emerge therefrom, and spin a small white cocoon on the trees and in the neighbourhood of the fruit-buds. Here they remain until the next spring, when they come out of their winter retreat and bore into the shoot, with what results has been already shown. The caterpillars are reddish, and so small when they are exposed that it would be practically impossible to see them. They are, moreover, not to be reached by insecticides once they have taken up their abode in the shoots. What, therefore, might be done is to syringe into the bushes something which, while it would not affect the fruit, would kill the larvæ. Killmright or similar soft soap preparations would answer very well. At pruning time, too, the bushes should be carefully gone over with a glass, and if the insects' presence be detected, all prunings should be carefully burned.

CUSCUTA. SYNS. *Buchingera, Cuscutina, Cussutha, Engelmannia, Epilinella, Grammica, Lepidanche, Monogynella, Succuta.* This genus includes about eighty species, broadly dispersed over the temperate and warmer regions of the globe.

CUSCUTINA. A synonym of **Cuscuta** (which *see*).

CUSP. A short, sharp point.

CUSPARIA (from *Cusparé*, the Venezuelan name for the bark of *Cusparia febrifuga*, which yields a valuable febrifuge, now enumerated in the British Pharmacopœia). ORD. *Rutaceæ*. A genus embracing about a score species of mostly small, stove trees, of Palm-like habit, with unbranched stems and a crown of handsome leaves, natives of tropical America; it was included by Bentham and Hooker under *Galipea*, but is now considered distinct. Petals more or less completely combined, in some cases forming a vase-like corolla. The following species thrive in a compost of loam and leaf-mould, and may be increased by seeds.

C. heterophylla (variable-leaved). *fl.* borne in supra-axillary racemes. *l.* lanceolate, the mid-nerve slightly pubescent. *l.* three- to five-foliolate, borne on long petioles. Brazil.

C. macrophylla (large-leaved). The correct name of *Galipea macrophylla.*

Cusparia—*continued.*

C. odoratissima (very sweet-scented). The correct name of *Galipea odoratissima.*

C. undulata (waved). *fl.* white, about ⅜in. long, borne in racemes from the axils of the leaves, which overtop them. *l.* palmately compound, with five leathery leaflets. Probably Brazil, before 1836.

CUSSUTHA. A synonym of **Cuscuta** (which *see*).

CUSTARD APPLE of the United States. *See* **Asimina triloba.**

CUT-FINGER. *See* **Vinca major.**

CUT-TOOTHED. Having deep and sharp teeth.

CYAMUS. A synonym of **Nelumbium** (which *see*).

CYANANTHUS (of Griffith). A synonym of **Staurantherа** (which *see*).

CYANASTRUM (from *kyanos*, blue, and *astron*, a star; in allusion to the colour and form of the flowers). ORD. *Hæmodoraceæ*. A monotypic genus. The species is a stove plant, not yet in general cultivation.

C. cordifolium (cordate-leaved). *fl.* purple, stellate, 1in. across, on short, erect scapes. *l.* cordate, 6in. long; petioles 9in. long. Rootstock creeping. Western Tropical Africa, 1894.

CYANITIS. A synonym of **Dichroa** (which *see*).

CYANOPHYLLUM. This genus is included, by the authors of the "Genera Plantarum," under **Miconia** (which *see*). To the species described on pp. 414-15, Vol. I., the following should be added:

C. aspersum (besprinkled). This species is something in the way of *C. magnificum*, but the leaves are more elongated, and are coated with a most delicate down, which gives them a beautiful, velvety appearance. Habitat not recorded, 1893.

CYANOTHAMNUS. Included under **Boronia** (which *see*).

CYANOTIS. SYNS. *Tonningia, Zygomanes.* Including *Erythrotis.* This genus is distributed over the warmer regions of the globe.

C. vittata (striped). A synonym of *Zebrina pendula.*

CYANOTRIS. A synonym of **Camassia** (which *see*).

CYANUS. Included under **Centaurea** (which *see*).

CYATHEA. Including *Metaxya.* This genus, which embraces about eighty species, natives of tropical and sub-tropical regions, contains some of the most beautiful of all known Tree-Ferns. As regards the beauty of their foliage, they are equal in every respect to any *Alsophila* or *Hemitelia*, with which they are closely connected, while they offer a great variety in the sizes of their trunks; those inhabiting temperate regions, such as *C. dealbata*, *C. medullaris*, &c., are mostly stout and destitute of spines, whereas most of the tropical kinds are slender compared with their height, and, in many cases, are densely armed with stout spines. All the species are evergreen, and to make good growth they require an abundance of water at the roots, and their trunks to be kept constantly moist. By these means only can Cyatheas be induced to produce fine heads of fronds, which last all the longer on the plants if they have gradually been inured to the sun during the summer. Like all other Tree-Ferns, Cyatheas are satisfied with very little pot-room. The soil in which they should be potted, tubbed, or, better still, planted in the Fernery, is a mixture of three parts fibrous peat, one of loam, and one of coarse silver-sand. All are of very easy culture,

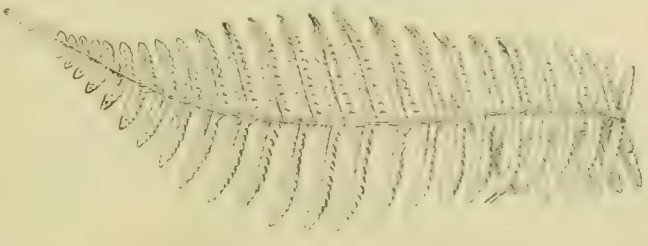

FIG. 285. PINNULE OF CYATHEA INSIGNIS

Cyathea—*continued.*

and, provided the moisture about the trunk and the roots be well attended to, there need be very little fear of failure in their cultivation. None among the numerous species known is in the habit of producing adventitious growths along the trunk or at the base, and none is known to be proliferous. The plants are therefore usually propagated from their spores, which are abundantly produced and germinate freely, making very showy young plants in the course of a couple of seasons.

C. medullaris is of very rapid growth; when planted in a conservatory where plenty of room can be allowed for its perfect development, it makes a good-sized stem or trunk in a comparatively short time, and proves by far the most imposing of all known Tree-Ferns which will succeed under cool treatment.

To those described on p. 415, Vol. I., the following should be added:

C. aculeata (prickly). A garden synonym of *Alsophila aculeata.*

C. Beyrichiana (Beyrich's). A synonym of *Hemitelia setosa.*

C. dealbata. Of this species there is a coloured variety, *tricolor.*

C. funebris (funereal). A garden synonym of *C. sclerolepis.*

C. horrida (horrid). A synonym of *Hemitelia horrida.*

C. insignis. A pinnule of this magnificent stove species is shown in Fig. 285.

C. Lindeniana (Linden's). A garden synonym of *C. mexicana.*

C. Mastersiana (Dr. Masters'). A provisional name for a plant with a caudex apparently not longer than 3ft., surmounted by graceful fronds 3ft. to 4ft. long, the basal part densely spiny. Habitat not recorded, 1894.

FIG. 286. CYATHEA MEDULLARIS.

C. medullaris. The habit of this magnificent and popular greenhouse species is shown in Fig. 286.

C. mexicana (Mexican). *fronds* bipinnate; pinnules smooth, spear-shaped, 3in. to 4in. long, cut into oblong, slightly sickle-shaped lobes. *sori* disposed chiefly in the lower half of the lobe, on the back of a simple vein or at the forking of a divided vein; involucres thin and fragile. Mexico. Stove. SYNS. *C. Lindeniana* (of gardens), *Alsophila Van Geertii.*

C. microphylla (small-leaved). *cau.* 4ft. high. *sti.* and rachises rusty-tomentose. *fronds* 2ft. to 3ft. long, oblong-ovate, acuminate, tripinnate; primary pinnæ sessile, broadly oblong, acuminate; secondary ones similar but smaller, crowded; pinnules scarcely two lines long, ovate-oblong, deeply pinnatifid; lobes entire. *sori* solitary at the base of the veinlet; involucre globose. Andes of Peru and Ecuador, 1883. Greenhouse.

C. princeps (foremost). A synonym of *C. insignis.*

C. pygmæa (dwarf). A provisional name for a plant having a caudex about 2ft. high, and soft, dark green fronds remarkable for the absence of the shiny appearance of most species of this genus. Habitat not recorded, 1894.

C. sclerolepis (hard-spined). *sti.* greyish, rough with hard and sharp points, furnished at base with firm, shining, brownish-black scales. *fronds* smooth, seldom more than 1ft. long, tripinnate; pinnæ less than 1ft. long; pinnules sessile, 2in. long, cut down into blunt, entire, sickle-shaped segments. *sori* small, abundant; involucres parchment-like. New Caledonia. Stove. SYN. *C. funebris* (of gardens).

C. sinuata (sinuate). A synonym of *Schizocæna sinuata.*

C. Smithii (Smith's). A synonym of *Hemitelia Smithii.*

C. spinulosa (slightly spiny). *sti.* and main rachis strongly aculeate, often dark purple. *fronds* glabrous, ample, somewhat flaccid; pinnules oblong, acuminate; lobes acute, serrulated, having small, bullate scales on the costules beneath. *sori* copious, close to the costules; involucre globose, very thin, membranous, soon breaking irregularly. India, 1883. Stove. (H. S. F. 12 c.)

CYATHIFORM. Shaped like a wine-glass.

CYATHOSTYLES. A synonym of **Cyphomandra** (which *see*).

CYBELION. A synonym of **Ionopsis** (which *see*).

CYBIOSTIGMA. A synonym of **Ayenia** (which *see*).

CYCAS. About fifteen species, natives of tropical Asia, Africa, Australia, and Polynesia, are here included. To those described on p. 416, Vol. I., the following should be added:

C. angulata (angled). *l.* borne on tetragonal petioles; pinnæ lanceolate-linear, the lower ones opposite, the upper ones alternate and much smaller; rachis ancipitous nearly to the apex. Australia, 1874.

C. Beddomei (Beddome's). *l.* about 3ft. long and 9in. broad; segments about ¼in. broad; rachis sub-quadrangular; petiole quadrangular, furnished at the base with tufted tomentum, and in the upper third with a few minute teeth. *cones* (males) about 13in. long and 3in. in diameter, slightly stipitate, the scales tapering from a deltoid base, acuminate. Stem (? young) a few inches high, with closely imbricated, glabrescent leaf-bases. India, 1883. Sir W. Thiselton Dyer considers this a reduced form of *C. circinalis.* (T. L. S., ser. ii., vol. ii., p. 85.)

C. Bellefonti (Marquis de Bellefont's). *l.* recurved, glabrous, elliptic, pinnatisect; leaflets sessile, linear-lanceolate, 3½in. to 4in. long, acuminate at apex, the margins flat, glaucescent; petioles short, spinulose at base, the spines small, straight. Trunk short, cylindrical, erect, clothed with fuscous-greyish scales. Tonkin, 1886. (I. H. 1886, 586.)

C. Boddami (Boddam's). A garden synonym of *C. pluma.*

C. Duivenbodei (Duivenbode's). *l.* pinnate, 3ft. to 3½ft. long; leaflets crowded, acuminate, 1in. broad. Trunk spiny, covered with blackish-brown scales. Moluccas, 1886.

C. inermis (unarmed). *l.* much like those of *C. revoluta*, but with rather broader pinnæ, which are very numerous, linear, spiny-acuminate, and revolute on the margins; petioles usually unarmed. Cochin China, 1848.

C. pluma (plume). According to Sir W. Thiselton Dyer, this only differs from *C. circinalis* in its smaller leaves with narrower leaflets. 1877. SYNS. *C. Boddami* and *C. squamosa* (of gardens).

C. squamosa (scaly). A garden synonym of *C. pluma.*

C. undulata (wavy). *l.* having undulated, acute, herbaceous pinnæ; petioles wholly pilose. Habitat uncertain, 1831. Closely allied to *C. circinalis.*

C. Wendlandii (Wendland's). This is described as "a handsome species from Madagascar, somewhat resembling the Dioons in habit, but differing in the leaflets, which are not serrated." 1895.

C. Armstrongii and *C. imperialis* are also, or have been, in cultivation.

CYCLAMEN. This genus is distributed over Central Europe, Western Asia, and the Mediterranean region. To the species, &c., described on pp. 417-8, Vol. I., the following should be added:

C. alpinum (alpine). *fl.* purple-red, with a blackish eye. *l.* small, marked with white. Asia Minor, 1892. A very dwarf plant, probably a form of *C. europæum* from a high elevation.

C. Atkinsi (Atkins's). A variety of *C. ibericum.*

Cyclamen—*continued.*

C. Clusii (Clusius'). An Italian form of *C. europæum.*

C. colchicum (Colchican). This differs from *C. europæum* mainly in having wider and more obtuse corolla segments, and larger leaves and tubers. Caucasus, 1897.

C. cyprium (Cyprian). A synonym of *C. neapolitanum.*

C. hederæfolium (Ivy-leaved). A synonym of *C. repandum.*

C. libanoticum (Lebanon). *fl.* white, shading to deep pink, with a dark crimson spot at the base, sweetly scented, about 1in. wide; peduncles about 6in. long. January and February. *l.* developed before the flowers, orbicular, with a white zone, very firm in texture. Corms large, irregular shaped. Palestine. A very fine, hardy species; it prefers a half-shady situation.

C. littorale (shore-loving). An Italian form of *C. europæum.*

C. orbiculatum (orbicular). A variety of *C. Coum.*

C. Peakianum (Peak's). An Italian form of *C. europæum.*

FIG. 287. CYCLAMEN PERSICUM.

C. tauricum (Taurian). *fl.* pure white. *l.* large, often marked with silvery-grey. Taurus, 1892. This also is probably a variety of *C. europæum.*

C. vernum (vernal). A synonym of *C. repandum.*

Varieties. Amongst the *C. Persicum* varieties (Fig. 287), the following may be named:

FIMBRIATA, the flowers of this section are of the usual form, but the foliage is deeply fimbriated; GRANDIFLORA ALBA, flowers very large, and pure white; PAPILIO, the flowers of this section have a great range of colour, and the petals of each being much fimbriated, give the flowers the appearance of a butterfly; VIVID, a very dark scarlet flower, very large.

CYCLANTHACEÆ. A natural order of perennial herbs or shrubs, all natives of tropical America. Flowers monœcious, arranged in superposed cycles or in a continuous spiral; spadices axillary, solitary, pedunculate, simple, rather short, cylindrical or oblong; spathes two to six, inserted on the peduncle, including the immature spadix, caducous; peduncle short or elongated, sheathing at base. Leaves distichous or spirally disposed, petiolate, flabellate, entire, bifid, or bipartite, parallel-nerved, complicate in vernation; petioles short or elongated, sheathing at base. *Carludovica palmata* yields the much-valued straw from which are manufactured Guayaquil or Panama hats. The order embraces four genera—*Carludovica*, *Cyclanthus*, *Ludovia*, and *Stelestylis*—and, as at present known, about thirty-five species.

CYCLANTHERA (from *kyklos*, a circle, and *anthera*, an anther; in allusion to the disposition of the anthers). SYN. *Discanthera.* ORD. *Cucurbitaceæ.* A genus embracing about a score species of stove, climbing annuals, with a perennial root. Flowers yellow, greenish, or white, monœcious, sometimes six-parted, usually minute; males racemose; females solitary. Fruit obliquely ovoid, somewhat fleshy, bristly or spiny. Leaves entire, lobed, or pedately five- to seven-foliolate. Tendrils simple or cleft twice or more. Only one species calls for mention here. For culture, *see* **Gourds.**

C. pedata (pedate). Climbing Cucumber. *fl.*, male racemes axillary, as long as the leaves; females scarcely prickly. *fr.* glaucous-green, ovate, acute, fistular, clothed with soft prickles. *l.* cordate, pedately (about) five-lobed; lobes mucronate, lightly argutely-serrated, slightly scabrous on both sides; sinus rounded. Tendrils bifid. *h.* 15ft. to 18ft. Mexico.

CYCLANTHUS (from *kyklos*, a circle, and *anthos*, a flower; in allusion to the spiral arrangement of the flowers). SYNS. *Cyclosanthes*, *Discanthus.* ORD. *Cyclanthaceæ.* A small genus (four or five species?) of stove, perennial, stemless, milky herbs. Flowers odorous, the males and females superposed in alternate rings, or disposed in a confluent spiral; spathes numerous; peduncle very long, naked or bracteate, cylindrical. Leaves clustered, long-petiolate, bifurcate: segments lanceolate, one-ribbed, plicate, parallel-nerved; petioles terete, sheathing at base. For culture of the species introduced, *see* **Carludovica.**

C. bipartitus (bipartite). *fl.*, spadix straight, cylindrical; spathe yellow, four-leaved, spreading; scape 2ft. long. *l.* plicate, sometimes entire, ovate-lanceolate, but more frequently divided more or less deeply in the upper portion—sometimes even to the base—into two lanceolate-linear lobes; petioles 3ft. to 6ft. long. Guiana.

C. cristatus (crested). *fr.*, spadix 7in. to 8in. long, 2in. in diameter, oblong. *l.* shortly petiolate, 3ft. long, deeply bifid; lobes oblong, falcate-connivent, acute, 4in. to 5in. broad. Colombia.

C. discolor (two-coloured). *l.* bifid, the two divisions lanceolate, with a tapered point more or less frilled at the edges; young leaves streaked with a tawny-orange hue, which passes off as they become matured. 1882. A remarkable plant.

C. Godseffianus (Godseff's). *l.* rich green, oblong-obovate, tapering to a sheathing stalk. Habitat not recorded, 1892.

CYCLONEMA. Included under **Clerodendron** (which *see*).

CYCLOPIA (from *kyklos*, a circle; in allusion to a roundish mark on the standard). This is the correct name of the genus described on p. 171, Vol. II., as *Ibbetsonia*, which includes about nine species. Flowers yellow, solitary on axillary peduncles; petals about as long as the calyx; standard nearly orbicular, twisted at base, with a short, recurved claw; wings oblong; keel incurved, obtusely beaked. Pods oblong, flat, compressed. Leaves sessile, digitately trifoliolate, or rarely with but one leaflet; stipules wanting. *C. genistoides* is probably the only species in cultivation.

CYCLOPOGON. A synonym of **Spiranthes** (which *see*).

CYCLOSANTHES. A synonym of **Cyclanthus** (which *see*).

CYCLOSIA. A synonym of **Mormodes** (which *see*).

CYCNOCHES. About fourteen species, natives of tropical America, are included in this genus. Flowers unisexual; sepals sub-equal, free, spreading; petals similar, but rather broader; lip fleshy, continuous with the base of the column, spreading, contracted into a claw at the base, above lanceolate or orbicular, entire, or variously lobed, crested, or fringed. To the species described on p. 419, Vol. I., the following should be added. *See also* **Luddemannia.**

C. barbatum. The correct name is *Polycycnis barbata.*

C. chlorochilum. The flowers of this species are very clearly shown in Fig. 288, while Fig. 289 gives a good idea of the general habit of the plant.

C. Haagii (Haag's). *fl.* 2in. to 2½in. broad, five to seven in inclined racemes; sepals and petals yellowish-green, brownish-green at back; lip white or suffused with pale rose, sparsely spotted with reddish-brown, cordate at base; column long, slender, speckled with reddish-purple below. October. *l.*, lower ones 3in. to 4in. long, oblong-lanceolate; upper ones 6in. to 8in. long, recurved, lanceolate. Stem 6in. high, 1in. thick. Brazil, 1891. (B. M. 7502.)

Cycnoches—*continued.*

FIG. 288. FLOWERS OF CYCNOCHES CHLOROCHILUM.

C. musciferum. The correct name is *Polycycnis muscifera.*

C. peruvianum (Peruvian). *fl.* disposed in a drooping raceme; sepals and petals pale green, spotted with purplish-brown; lip white, cut into radiating, clavate processes. Peru, 1891. A curious species, allied to *C. ventricosum.* (L. vii., t. 301.)

C. Pescatorei (Pescatore's). A synonym of *Lueddemannia Pescatorei.*

C. Rossianum (Ross's). *fl.*, males yellowish-green, with brown spots, 1½in. in diameter, disposed in slender racemes; females bright green, solitary, twice as large as the males. Origin unknown, 1891.

C. stelliferum (star-bearing). A synonym of *C. Warscewiczii.*

C. versicolor (various-coloured). *fl.*, males 2in. to 2½in. in diameter, many in pendulous racemes; sepals and petals tawny-green with a velvety gloss and with close-set, longitudinal, brown lines; lip creamy-white, spotted with red in the front of the two erect teeth in the apical part; female flowers unknown. Brazil, 1888.

CYCOCTONUM ROSEUM. A synonym of **Cynanchum roseum** (which *see*).

CYDONIA. SYN. *Chænomeles.* Bentham and Hooker include this genus under *Pyrus*, but for horticultural purposes it has been kept distinct in this work. To the species and varieties described on p. 419, Vol. I., the following should be added:

C. citripomma (Citron-fruited). *fl.* of a brilliant cherry-red, large. Spring. *fr.* orange-yellow, with an agreeable odour, egg-shaped; flesh yellow, firm, juicy, more or less acid;

Cydonia—*continued.*

September and October. *l.* lanceolate or oblong-elliptic, attenuated at both ends, finely toothed. Raised from seeds in 1869. SYN. *Chænomeles citripomma* (R. H. 1876, 331; 1891, f. 11).

C. Japonica Semirenkiana (Semirenk's). A garden sport with creamy leaves. 1883.

C. j. serotina (late). A late-flowering form of the typical *C.* (*Pyrus*) *japonica.* 1894. (R. H. 1894, p. 424, f. 155, 156, under name of *Chænomeles japonica serotina.*)

C. vulgaris marmorata (marbled). A garden variety, having the leaves variegated with white and yellow. 1890.

CYLICADENIA. A synonym of **Odontadenia** (which *see*).

CYMATION. A synonym of **Ornithoglossum** (which *see*).

CYMBIDIUM. SYN. *Iridorchis.* Many of the more popular Cymbidiums, such as *C. Lowianum*, *C. giganteum*, *C. cyperifolium*, *C. grandiflorum* (*Hookerianum*), and the now plentiful and lovely *C. Traceyanum*, are found to do better under cool conditions than when grown in the stove. A winter temperature of 50deg. is quite sufficient, with, say, a summer temperature of about 60deg. Under cooler conditions the plants do not require so much water. In winter especially it must be given with great discretion, or the result will be disastrous. Excessive moisture, with cool conditions inside the house, generally develop "black spot" and disfiguration of the foliage. This must be avoided by keeping the plants in a

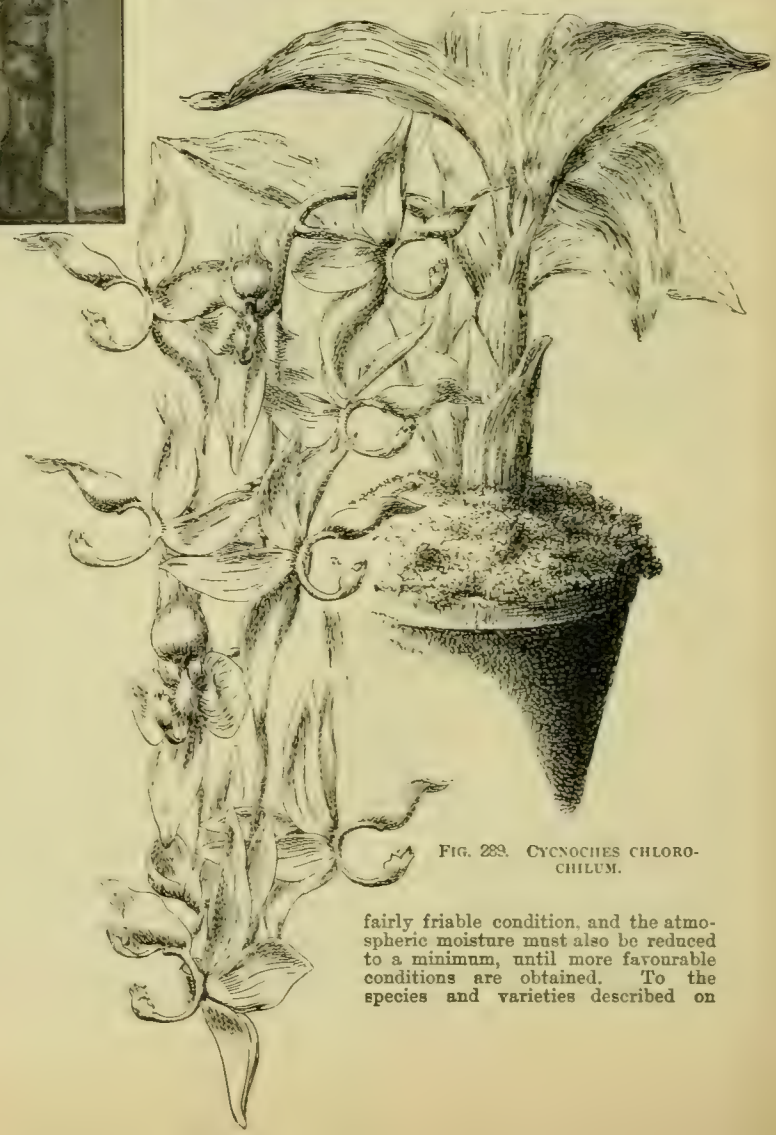

FIG. 289. CYCNOCHES CHLOROCHILUM.

fairly friable condition, and the atmospheric moisture must also be reduced to a minimum, until more favourable conditions are obtained. To the species and varieties described on

Cymbidium—*continued.*

pp. 420-1, Vol. I., the following should be added. *See also* **Cyperorchis.**

C. affine is probably identical with, or a form of, *Cyperorchis Mastersii.*

C. albucæflorum (Albuca-leaved). A synonym of *C. madidum.*

C. chloranthum (yellow-flowered). *fl.* 2in. across; sepals and petals yellowish-green, with a few red spots at the base; lip three-lobed, the side lobes red on the inside incurved, the front lobe yellowish-white spotted with red; column yellow, stained with red; racemes 15in. to 20in. long, many-flowered. May. *l.* ensiform, 15in. to 20in. long, recurved Probably Australian, 1840. (B. M. 4907.)

C. cyperifolium (Cyperus-leaved). *fl.* four to seven, distant, fragrant; sepals and petals pale green and yellow, streaked with red, acute; lip greenish or white, spotted with red, narrow; scape shorter than the leaves. *l.* rigid, 2ft. to 3ft. long, ¼in. to ½in. broad. Sub-tropical Himalaya, &c., 1895.

C. Dayanum is a variety of *C. eburneum.*

C. eburneum Philbrickianum (Philbrick's). *fl.* white; sepals and petals narrow; side lobes of the lip well apart from the narrower middle lobe; callus narrow, with a most obscure mid-keel. 1886. Habit that of *C. Parishii.*

C. elegans (elegant). A synonym of *Cyperorchis elegans.*

C. ensifolium (sword-leaved). *fl.* greenish-yellow, very fragrant; sepals and petals marked with some reddish-brown, narrow lines; lip dotted, ovate, somewhat recurved; scape terete, few-flowered. Late summer. *l.* ensiform, nerved. China and Japan. (B. M. 1751.)

C. e. estriatum (not striated). *fl.*, segments very narrow; sepals green, with a few red lines; petals white, with some purple lines; lip white, the middle lacinia yellow, with a few brown spots; column white, with purple blotches in front. *l.* more than 1ft. long, ½in. broad, with dark spots. Assam, 1887.

C. Finlaysonianum (Finlayson's). *fl.* 2½in. across; sepals and petals dull yellow, linear-lanceolate; lip not saccate, the side lobes streaked with red, the mid-lobe white, reddish-purple towards the tip; raceme slender, 2ft. to 3ft. long. Habit as *C. aloifolium.* Penang. SYN. *C. pendulum* (B. R. 1840, t. 25).

C. Gibsoni (Gibson's). A synonym of *C. lancifolium.*

C. grandiflorum (large-flowered). The correct name of *C. Hookerianum.*

C. g. punctatum (dotted). This form has purplish dots on the lower parts of the segments. 1893. (L., t. 389.)

C. g. Tracyanum (H. Tracy's). A large-flowered variety. 1890. (J. H. ser. iii., xxi., p. 535, f. 71.)

C. Hookerianum. The correct name is *C. grandiflorum.*

C. Humblotii (Humblot's). *fl.* green and black, resembling those of *Cœlogyne pandurata,* but smaller; sepals 1½in. long; petals 1¼in. long, concave; lip three-lobed; panicle branched, erect, 3ft. high, many-flowered. *l.* linear, acute, 1½ft. to 1½ft. long. Stems rhizomatous. Madagascar, 1892.

C. Huttoni is now regarded as synonymous with *Grammangis Huttoni.*

C. lancifolium (lanceolate-leaved). *fl.* 1½in. to 2in. in diameter; sepals white, yellowish, or greenish, lanceolate; petals white, with a pink midrib, rather broader; lip white, spotted with reddish-purple, the side lobes narrow; scape nodding, six- to eight-flowered. *l.* 6in. to 10in. long, long-petiolate. Stem 2in. to 6in. long, fleshy, fusiform. Sub-tropical Himalaya, 1822. (L. B. C. 927.) SYN. *C. Gibsoni* (P. F. G. iii., p. 618, f. 301).

C. Lowianum is probably a variety of *C. giganteum.*

C. L. aureum (golden). *fl.* yellow, with a blotch of orange on the lip. 1893.

C. L. flaveolum (yellowish). *fl.* of a pale yellow, large. 1897. (L., t. 572.)

C. L. superbissimum (most superb). *fl.* having the front lobe of the lip deep maroon-purple. 1893. (L., t. 392.)

C. L. viride (green). *fl.* greenish-yellow without any purple on the lip. 1892.

C. madidum (dyed). *fl.* 1in. in diameter; sepals spreading, petals smaller and erect, both (as well as the mid-lobe of the lip) dull nankeen-yellow; side lobes of lip stained with vinous-purple, erect; racemes pendulous, as long as the leaves, many-flowered. Stems pseudo-bulbous, 3in. to 4in. long. Australia, 1840 and 1889. SYN. *C. albucæflorum.*

C. marginata (margined). A synonym of *Maxillaria marginata.*

C. Mastersii is now removed to *Cyperorchis.* (L., t. 222.)

C. Parishii is a variety of *C. eburneum.*

C. pendulum (of Bot. Reg.). A synonym of *C. Finlaysonianum.*

C. pubescens (downy). *fl.* 1in. to 1¼in. broad; sepals and petals dark purple, margined with yellow or green, linear; lip pubescent, yellow, with a broad band of reddish-purple, or reddish-purple within the margin of the mid-lobe, the side lobes acute; raceme short, pendulous, six- to ten-flowered; scape short, decurved. *l.* 1ft. to 2ft. long, ½in. broad, obtuse. Singapore and Borneo, 1838. (B. R. 1841, t. 38.)

Cymbidium—*continued.*

C. pulcherrimum (very pretty). *fl.* of a waxy white, striped and flushed with crimson; sepals and petals narrow, acute; raceme slender; scape stout. *l.* Grass-like. Northern India, 1891. A charming species.

C. Tracyanum (Tracy's). A form of *C. grandiflorum.*

The following are hybrids:

eburneo-Lowianum	*Lowianum* and *eburneum* (Veitch).
Lowio-eburneum	*eburneum* and *Lowianum* (Rothschild).
Winnianum	*giganteum* and *eburneum* (?) *Mastersianum* (Winn).

CYMBURUS. A synonym of **Stachytarpheta** (which *see*).

CYMINOSMA. A synonym of **Acronychia** (which *see*).

CYNANCHUM. SYNS. *Diploglossis, Endotropis.* To the species described on p. 421, Vol. I., the following should be added. Several plants formerly included here are now referred to **Dæmia, Gonolobus, Marsdenia, Tylophora,** and **Vincetoxicum.**

C. formosum (beautiful). *fl.* pale green, pedicellate; corolla with five spreading or reflexed lobes that are nearly ¼in. long; cymes elegant, 2½in. to 3½in. long; peduncles ¼in. to 2½in. long. *l.* ovate, elliptic-ovate, or oblong-ovate, 1¼in. to 4in. long, cuspidate-acuminate, cordate at base; petioles ¼in. to 1¼in. long. Peru, &c., before 1855, and 1895. Plant twining, wholly glabrous. A distinct species.

C. macrorhizon and *C. purpurascens* have also been introduced.

CYNIPS KOLLARI. *See* **Oak Galls.**

CYNOCRAMBE. A synonym of **Thelygonum** (which *see*).

CYNOGLOSSUM. About sixty species, broadly dispersed over temperate and sub-tropical mountainous regions, are included in this genus. To those described on p. 421, Vol. I., the following should be added. Several plants formerly classed hereunder are now referred to **Lindelofia, Omphalodes,** and **Paracaryum.**

C. furcatum (forked). *fl.* of a beautiful, clear blue, resembling a Forget-me-not, in terminal spikes. June and July. *l.* large, lingulate, acute, greyish-green. Stems erect, branched, forming a bushy tuft 1½ft. in height. India, reintroduced in 1897. A charming biennial.

C. nervosum (prominently nerved). *fl.* of a very deep cobalt-blue, nearly ½in. across; racemes many, axillary and terminal, 3in. to 6in. long, loosely many-flowered. May. *l.*, radical and lower ones 6in. to 10in. long, narrowly oblanceolate, acute, with six or more pairs of strong, scabrid nerves; petioles 2in. to 3in. long. *h.* 3ft. Western Himalayas, 1894. Plant strigillosely pubescent all over. (B. M. 7513.)

CYNORCHIS (from *kyon, kynos,* a dog, and *Orchis;* a name altered by Lindley from the *Cynosorchis* of Thouars). SYN. *Cynosorchis.* ORD. *Orchideæ.* A genus embracing about sixteen species of stove, terrestrial Orchids, with the habit of *Habenaria rotundifolia,* natives of the Mascarene Islands and tropical Africa. Flowers mediocre or rather small, shortly pedicellate; sepals subequal, concave, at length spreading; petals similar or smaller; lip continuous with the column, spreading, as long as the sepals, three- to five-cleft, produced in a spur; column very short; raceme short or rarely elongated, rather loose. Four species call for description. For culture, *see* **Bletia.**

C. elegans (elegant). *fl.* whitish, with a rosy tinge, disposed in three- to seven-flowered racemes; odd sepal gibbous, convex, abrupt over the triangular, acute apex; side sepals ligulate, acute or blunt-acute, longer than the odd sepal; lip with a small angle on each side at the base, the lamina spotted or lined deep purple; scape slender. *l.* cuneate-oblong-lanceolate, acute, 2½in. long by ¾in. wide, light green, striped and barred mauve-purple. Madagascar, 1888.

C. grandiflora (large-flowered). *fl.* 1½in. across; sepals and petals greenish, spotted with purple, small; lip bright rose-purple, large, four-lobed, with a long spur; scapes erect, 1ft. long, one- or two-flowered. *l.* ensiform, annual. Madagascar, 1893. (B. M. 7564; G. C. 1893, xiii., p. 197, f. 29.)

C. g. albata (whitish). *fl.* scented; lip white, purple at base.

C. g. purpurea (purple). *fl.* scentless; lip purple, spotted at base.

C. Lowiana (Low's). *fl.*, sepals and petals whitish-green; lateral sepals oblong, obtuse; odd sepal convex-oblong, blunt-acute, shorter than the lateral ones; petals ligulate, acute; lip lilac, three-cleft, the lateral laciniæ linear, extrorse, the mid-lacinia

Cynorchis—*continued.*

deeply two-cleft, with a deep purple, obcordate spot at base. *l.* one or two, about 9in. long, ⅔in. wide, dark green. Madagascar, 1888.

C. purpurascens (purplish). *fl.*, dorsal sepal green and red, ¼in. long, the lateral ones pale green, ¼in. long; petals rose, ¼in. long; lip bright rose-red, 1¼in. long; peduncle 6in. to 10in. long, two- to ten-flowered. November. *l.* solitary (or with a reduced second), 6in. to 8in. long, lanceolate or oblong-lanceolate, acuminate. Madagascar, &c., 1894. (B. M. 7551.)

CYNOSORCHIS. A synonym of **Cynorchis** (which *see*).

CYNOTIS. A synonym of **Cryptostemma** (which *see*).

CYPELLA. Including *Phalocallis*. This genus embraces eight species, natives of tropical America, differing from *Marica* in their terminal, single or corymbose flowers, plicate leaves, and terete stems.

C. brachypus (short-stalked). A synonym of *Marica brachypus*.

C. plumbea. SYN. *Phalocallis plumbea* (B. M. 3710; F. d. S. 395 and 1466).

CYPERORCHIS (from *Cyperus* and *Orchis*; in allusion to the resemblance to *Cyperus*, and the affinity to *Orchis*). ORD. *Orchideæ*. A small genus (two or three species) of stove, epiphytal Orchids, natives of the East Indies and the Malayan Archipelago, formerly included under *Cymbidium*. Flowers showy; sepals and petals sub-equal, free, erect or somewhat spreading; lip sessile at the base of the column, erect, narrow, concave, the lateral lobes embracing the column, the middle one short, broad, spreading; column rather long, erect, semi-terete; pollen masses two; raceme many-flowered; scape erect. Leaves long, narrow, scarcely dilated at base. Stem short, leafy, hardened or slightly thickened at base. For culture, *see* **Cymbidium**.

C. cochleare (ear-shaped). *fl.* 2in. long; sepals and the revolute petals greenish-brown, very narrow; lip yellow, speckled with red, the mid-lobe golden-yellow, sub-orbicular; raceme elongated; scape 1ft. to 1½ft. long. *l.* 2ft. to 3ft. long, ¼in. to ½in. broad. Sikkim Himalaya, 1880. SYN. *Cymbidium cochleare*.

C. elegans (elegant). *fl.* pale yellow or white, 1½in. long, inodorous, densely imbricated, remaining half-closed, cylindrical; lip having two orange lines on the disk; racemes nodding, many-flowered; scape 6in. to 18in. long, densely clothed with sheaths 2in. to 5in. long. Autumn. *l.* 1½ft. to 2ft. long. Nepaul, 1840. (B. M. 7007.) SYN. *Cymbidium elegans* (L. S. O. 14).

C. Mastersii (Dr. Masters'). The correct name of the plant described on p. 421, Vol. I., as *Cymbidium Mastersii*. (B. R. 1845, 50; F. M. n. s., t. 391; L. J. F., t. 289; P. F. G., t. 78; R., t. 66.) SYN. *Cymbidium affine* (?) (W. O. A. iii. 140).

C. M. album (white). *fl.* pure white, with the exception of the yellow keels; deliciously fragrant. Winter. India, 1889. (R., ii., t. 36, under name of *Cymbidium Mastersii album*.)

CYPERUS. Mariscus (which *see*), formerly included here, is now kept distinct. To the species, &c., described on p. 422, Vol. I., the following should be added:

C. alternifolius variegatus gracilis (slender). A sub-variety having filiform stems and leaves. 1893.

C. aristatus (awned). An annual species, scarcely 6in. high, native of Mexico, and described as "a pretty, decorative plant." 1893.

C. compressus (compressed). *fl.*, spikes of three to ten spikelets, very shortly spicate; glumes densely imbricated. *l.* often nearly as long as the stem, ⅛in. to ¼in. broad. Stems tufted, 4in. to 16in. long (or, in the dwarf form *pectiniformis*, often 2in. or less). Tropics, except Australia, 1870. Plant green, glabrous. Stove.

C. esculentus (edible). *fl.*, spikelets yellow or yellowish-brown; glumes plicate-striate over nearly their whole length. *l.* (and bracts) long. Stem erect at base. Stolons lateral, long, very slender, bearing tubers. South Europe, India, &c. Half-hardy.

C. distans (distant). A synonym of *Mariscus ferax*.

C. ferox (fierce). A synonym of *Mariscus ferax*.

C. gracilis (slender). A sub-variety of *C. alternifolius variegatus*.

C. laxus. Of this species there is a variegated-leaved form, *variegata*. 1881.

C. natalensis (Natal). A garden name for *Mariscus umbilensis*.

C. Papyrus (Papyrus). The correct name of *Papyrus antiquorum*.

C. reflexus (reflexed). This is described as "a graceful plant, densely tufted, with light green leaves." Argentina, 1895. Although a perennial, it flowers the same year when raised from seeds.

C. umbilensis. A synonym of *Mariscus umbilensis*.

CYPHIA. To the species described on p. 422, Vol. I., the following should be added:

C. tortilis (twisted). *fl.* lilac, axillary, small, solitary; petals recurved at apex. *l.* alternate, petiolate, glabrous, ¼in. to 1¼in. long, the lower ones spathulate-obovate or oblanceolate, the upper ones lanceolate or linear-lanceolate. Stem twining, glabrous. Tubers succulent, edible. South Africa, 1894.

CYPHOKENTIA. Two species of unarmed, stove Palms, natives of New Caledonia, form this genus. Flowers arranged as in *Cyphophœnix*; spathes two, deciduous; bracts short, continuous with the spadix; bracteoles small, imbricated, forming a short cup. Leaves terminal, pinnatisect; segments elongated-ensiform, narrowed at apex, the margins recurved at base.

CYPHOMANDRA. SYNS. *Cyathostyles*, *Pallavicinia*. Flowers pedicellate, racemose; corolla deeply five-lobed. Fruit an oblong or globose, usually large berry. Leaves entire, three-lobed, or pinnatisect.

CYPHONEMA. A synonym of **Cyrtanthus** (which *see*).

CYPHOPHŒNIX (from *kuphos*, bent, and *Phœnix*, a Palm-tree; in allusion to the curved spadix of one of the species in fruiting, and to the affinity of the genus). ORD. *Palmæ*. A small genus (two species) of stove, unarmed Palms, natives of New Caledonia, and closely allied to *Cyphosperma*. Flowers monœcious on the same spadix, spirally disposed in threes, a female between two males; spadix robust, paniculately branched, the branches elongated. Fruit brown, mediocre, elongated-ovoid or ellipsoid. Leaves terminal, pinnatisect; segments coriaceous, elongated-ensiform, narrowed at apex, thickened on the margins. There is a specimen of *C. elegans* (SYN. *Kentia elegans*) at Kew, but it is not in general cultivation.

CYPHOSPERMA. Flowers brown, arranged as in *Cyphophœnix*; spadix branches somewhat distichous; bracts short. Fruit brown, small, globose or cubical-ovoid. Leaves terminal, pinnatisect; segments narrow-ensiform, præmorse-toothed, thickened and recurved at base.

CYPRESS, AFRICAN. *See* **Widdringtonia.**

CYPRESS, DECIDUOUS. *See* **Taxodium distichum.**

CYPRIPEDIUM. SYN. *Criosanthes*. This genus embraces about sixty species, natives of Europe, temperate and tropical Asia, North America, and Mexico. With the exception of the Cattleya family, no Orchids have been so extensively used for hybridisation as the *Cypripedium* and *Selenipedium*. The result is that the increase in variety has been enormous. In many instances most successful and desirable forms have been produced, while in others practically failures have to be recorded. It is remarkable also that when failures have occurred such have been from the use of some of the best species. Take for example *C. Spicerianum*. Such a fine species naturally was looked upon as a likely parent, and extensively used. The records, however, show that though it has been used in the production of nearly a hundred distinct crosses, out of this number it would be difficult to name a dozen really good things. The majority are useful for cut-flower purposes, retaining the free-flowering characteristics of *C. Spicerianum*, but in point of beauty and quality they are not to be compared with the parent species.

The introduction of species during the past few years has brought fresh material to the hand of the hybridist, and this has enabled him to evolve a new section of hybrids. The most remarkable are those derived from the use of *C. bellatulum* as a parent. Still more wonderful is the rapidity with which these have been produced, as it was only in the year 1888 that *C. bellatulum* was first introduced. These crosses, as a reference to the list of hybrids will show, now reach a formidable total, and are more sought after and more valuable than any of the Cypripediums.

C. Rothschildianum has so far proved most successful in the few instances in which it has been used. Secondary hybrids also are now being freely produced, so that, in a few years' time, we may look forward to quite a new class.

Recently a fresh classification of the genus has been arranged. In the body of this work we recognised the natives of the Western hemisphere as Selenipediums—that is, the class to which *S. caudatum*, *S. Schlimii*, &c.,

Cypripedium—*continued.*

belong, retaining the original name of Cypripedium for the Eastern section. We still retain these names for the species and list of hybrids, as we do not consider the matter sufficiently familiar outside the "specialist" to adopt the newly classified names; but as they may be useful for reference purposes we give them together with a few of species in each division.

FIG. 290. FLOWERS OF HARDY CYPRIPEDIUMS.

CYPRIPEDIUM. This is confined to what is termed the hardy section (see Fig. 290), to which *C. pubescens*, *C. calceolus*, &c., belong.

PAPHIOPEDIUM includes the whole of the Eastern section, previously classed as Cypripediums.

PHRAGMIPEDIUM includes the species previously distinguished as Selenipediums, such as *S. caudatum*, *S. Lindleyanum*, *S. longifolium*, *S. Schlimii*, &c.

SELENIPEDIUM. This embraces three kinds practically unknown in cultivation. They are natives of Guiana, Brazil, and Central America—*S. chica*, *S. Isabellianum*, and *S. palmifolium* (of Reichenbach).

To those described on pp. 423-7, Vol. I., the following should be added. Except where otherwise indicated, they require stove treatment. Several species formerly included here are now referred to **Selenipedium.**

Cypripedium—*continued.*

C. Appletonianum (Appleton's). A form of *C. Bullenianum.*

C. Argus Moensii (Moens'). *fl.*, dorsal sepal and petals broader than in the type; spots on the petals larger and more numerous.

FIG. 292. CYPRIPEDIUM CALLOSUM SANDERÆ

C. barbatum Crossii. The correct name of *C. Crossii.* SYN. *C. orbum.*

C. b. Warnerianum (Warner's). *fl.*, dorsal sepal white, striped green towards the base, with a transverse band of vinous purple, large; petals green-striped above, white towards the base, the rest purple, tipped white; lip deep brownish-purple. March to May. *l.* distinctly tessellated. India. (W. S. O. iii. 11.) There is another variety, *Obrienii.*

C. bellatulum (rather pretty). *fl.* white or whitish-yellow, spotted all over, and as much as 11in. in circumference; staminode very long, oblong, tridentate at apex, beautifully spotted, almost free from hairs. *l.* 10in. long, 3in. wide, beautifully marbled with light, hieroglyphic spots on the upper surface, the lower one being covered with innumerable brown dots. 1883. See Fig. 291. The variety *album* has pure white flowers and green leaves. 1895.

C. Boxallii atratum (dark). *fl.*, dorsal sepal green, speckled blackish-brown; lip and lateral petals reddish-purple irregularly mixed with light green, the upper margin white. 1887. (G. C. 887, i., p. 210.)

C. Bullenianum (Bullen's). *fl.* somewhat smaller and appearing earlier than in *C. Hookeræ* (to which this species is allied); upper sepal with some blackish streaks at base; petals with three or four small, blackish warts on each margin, and having the dilated apical portion edged with pale yellowish-green. North Borneo, 1862. There are three varieties: *anophthalmum*, *Appletonianum*, and *oculatum.*

C. Burbidgei (Burbidge's). A synonym of *C. Dayanum.*

FIG. 291. FLOWERS OF CYPRIPEDIUM BELLATULUM.

Cypripedium—*continued.*

C. californicum (Californian). *fl.* 1in. to 1½in. across the petals; sepals pale brownish-yellow, the lateral ones united into a boat-shaped limb; petals dull yellow; lip white, with a little pink, and obscurely spotted with brown, obovoid-globose, hairy at base within. May. *l.* 3in. to 4in. long, acute. Stem 1ft. to 2ft. high, leafy. California, 1888. Half-hardy. (B. M. 7188; G. & F. 1888, p. 281.)

C. callosum (hard). *fl.* very large, remaining some weeks in perfection; dorsal sepal pure white, striped with dark chocolate-crimson, 2½in. across; petals and pouch soft rose or crimson on a greenish-white ground. Cochin China, 1885. *l.* oval-oblong, acute, 6in. to 9in. long, with blackish-green markings. Greenhouse. In growth this plant resembles a strong *C. barbatum*. (G. C. 1887, i., p. 315; J. H. 1887, p. 7, f. 1; L. ii., t. 73; R. H. 1888, p. 252.)

C. c. Sanderæ (Mrs. Sander's). *fl.* pale; dorsal sepal snow-white, with a few lines of emerald-green at base. 1894. See Fig. 292.

FIG. 293. FLOWER OF CYPRIPEDIUM CURTISII.

C. Chamberlainianum (Rt. Hon. J. Chamberlain's). *fl.* rosy-purple and white, in form somewhat resembling those of *C. spectabile*; sepals strongly pubescent at back; bracts large, boat-shaped; scapes 2ft. high. *l.* strap-shaped. New Guinea, 1892. (G. C. 1892, xi., p. 241, f. 34; Gn. 1893, p. 304; J. H. 1892, p. 294, f. 49; R. H. 1893, p. 141.)

C. Chantinii (Chantin's). A form of *C. insigne*.

C. Charlesworthii (Charlesworth's). *fl.*, dorsal sepal white, veined with rosy-purple, 2½in. wide, the lower one greenish-white, 1in. broad; petals yellowish, tinged with brown, 1½in. long; pouch similarly coloured, somewhat like that of *C. insigne*. 1893. Habit as *C. Spicerianum*. (G. C. 1893, xiv., p. 457, f. 70; J. H. 1893, p. 307, f. 43.)

C. ciliolare (ciliolated). This much resembles *C. superbiens*; sepals and petals having more numerous nerves and more hairy margins; nail of the lip shorter, and the staminode lower and broader; scapes 1ft. to 1½ft. high. *l.* narrow- or elliptic-oblong, 6in. or more in length. Philippines, 1882. (G. C. 1882, xviii., p. 488; I. H. 1884, t. 530.)

Cypripedium—*continued.*

C. concolor chlorophyllum (green-leaved). *fl.* covered with small spots. *l.* free from marbling. 1886.

C. c. Regnieri (Regnier's). *fl.* yellow, with a purple blotch on the outside of the sepals, the staminode ochre, dotted with purple, and having a white margin in front. *l.* large, well marbled. 1886.

C. c. sulphurinum (sulphur-coloured). *fl.* light sulphur, with two dark yellow blotches. 1888.

C. c. tonquinense (Tonkin). *fl.* larger than in the type. Tonkin, 1887. (L. ii. 77.) SYN. *C. tonquinense*.

C. Crawshayæ (Mrs. Crawshay's). *fl.* very large, dorsal sepal pure white, with a pale greenish spot at base; petals, lip, and lower sepals of a pale greenish-yellow. *l.* fleshy, bright green above, greyish beneath. Shan States, 1898. Allied to *C. Charlesworthii*, but quite distinct.

C. Crossii is a variety of *C. barbatum*.

C. Curtisii (Curtis'). This is much like *C. ciliolare*; the petals are narrower, with shorter ciliæ and smaller spots, which latter are numerous at the tops of the petals; lip large, with acute side angles. May and June. *l.* oblong or oval-oblong, 6in. to 8in. long, tessellated with deep and pale green. Sumatra, 1882. See Fig. 293. (G. C. 1890, vii., p. 557, f. 90; L. iii., t. 140; W. O. A. iii., t. 122.)

C. Elliottianum (Elliott's). A synonym of *C. Rothschildianum*.

C. Exul (exile). *fl.*, dorsal sepal white, yellow at base, irregularly blotched with purple; petals resembling those of *C. insigne*; lip like that of *C. Druryi*. *l.* as in *C. insigne*, but much stouter. Siam, 1892. (G. C. 1892, xi., p. 523, f. 77.)

C. E. Imschootianum (Imschoot's). *fl.* larger than in the type; dorsal sepals having darker spots. 1892. (L. vii., t. 327.)

C. fasciculatum (fascicled). *fl.* 1in. to 1½in. in diameter; sepals and petals greenish, lanceolate, acute; lip greenish-yellow, with a purplish-brown margin; spike one- to four-flowered. *l.* twin, ovate or broadly elliptic. North-west America, 1888. More interesting than beautiful. Hardy. (G. & F. 1888, i., p. 90, f. 16.)

C. glanduliferum (gland-bearing). An old name for *C. præstans*.

C. humile (dwarf). A synonym of *C. acaule*.

C. Hyeanum (Hye's). A form of *C. Lawrenceanum*.

C. insigne albens (whitish). *fl.* yellow and white, with scarcely any of the brown markings of the type. 1893.

C. i. albo-marginatum (white-margined). *fl.*, dorsal sepal yellowish-green, broadly margined white, spotted brown on the green part; petals tawny-yellow, with darker veins; lip pale brownish, yellow inside. India, 1886. A distinct variety. (W. O. A. 232.)

C. i. aureum (golden). This variety is remarkable for the golden glow which pervades the flowers, the colouring of which is in other respects of the normal character. 1882.

C. i. Chantinii (Chantin's). The correct name of *C. i. punctatum violaceum* (Gn. xxi., t. 342).

C. i. longisepalum (long-sepaled). *fl.* pale, unspotted; dorsal sepal 2½in. long. 1890.

C. i. montanum (mountain-loving). This name has been given to a series of forms, some of which are distinguished by their richly-marked flowers and by their shorter and narrower leaves. (L., t. 414.)

C. i. Mooreanum (Moore's). *fl.* 5in. in diameter; dorsal sepal greenish-yellow, striped green, broadly margined white, with very large, dull purple spots; petals pale yellowish-green, flushed rosy-crimson, blotched at base; lip bright bronze; spikes 18in. to 20in. long. *l.* 14in. long. 1887.

C. i. Sanderæ (Mrs. Sander's). *fl.* primrose-yellow, with a broad, white, apical margin, and a few brown dots on the central veins of the upper sepal. See Fig. 294.

There are several other minor varieties of *C. insigne*, but the preceding are all that call for description here.

C. javanicum (Javanese). *fl.* 3in. across vertically; sepals and petals pale green, ciliolated, the petals blackish-dotted and with one-third dull purple; lip brownish-green, nearly cylindrical, the infolded lobes spotted with purple; scapes one- or rarely two-flowered. *l.* elliptic-oblong, 6in. to 8in. long, sparingly mottled. Eastern Java, 1840. (F. d. S. vii., t. 703.)

C. j. virens (greenish). *See* **C. virens.**

C. lævigatum. The correct name is *C. philippinense*.

C. Lawrenceanum Hyeanum (Hye's). *fl.*, dorsal sepal white, veined green, large; petals ciliated; lip entirely green. Borneo, 1886. SYN. *C. Hyeanum*.

There are many other varieties of *C. Lawrenceanum*, mainly distinguished by the prominence and rich colour of the veins of the upper sepal, which colour is sometimes diffused over the greater part of the surface.

FIG. 294. FLOWER OF CYPRIPEDIUM INSIGNE SANDERÆ

C. macranthon [not *macranthum*]. See Fig. 295. There is a variety *ventricosum* (S. B. F. G. iv., t. 1) with sepals and petals often 2in. long and the lip lin. to 1½in. in diameter. Thibet, Siberia, &c., 1877.

C. margaritaceum (pearly). *fl.*, sepals and petals deep purple, with rows of blackish-purple dots, shortly ciliated; lip dark brown, covered with small tubercles, slightly concave above, with a circular orifice formed by the short auricles overlapping each other; scape one-flowered. *l.* twin, glaucous-green, spotted with purplish-brown. Yunnan, China, 1888.

C. montanum (mountain-loving). *fl.* brownish-purple, with a white lip, striped with red inside; column yellow, spotted with crimson. *l.* lanceolate, pubescent. *h.* about 1ft. Oregon, 1883. A beautiful little, hardy Orchid. (B. M. 7319; F. & P. 1883, p. 10.) SYN. *C. occidentale* (R. G. 1036).

C. nigritum (blackish). *fl.* near those of a dark variety of *C. barbatum*; dorsal sepal oblong, acute, the lateral ones forming a very narrow body; petals much narrower than the dorsal sepal. *l.* like those of *C. virens*. Borneo, 1882.

C. occidentale (Western). A synonym of *C. montanum*.

C. orbum (orb-like). A synonym of *C. barbatum Crossii*.

C. Pearcei (Pearce's). A synonym of *Selenipedium caricinum*.

C. philippinense (Philippines). The correct name of *C. lævigatum*. SYN. *C. Roebelenii*.

C. Pitcherianum (Pitcher's). A synonym of *C. Argus*.

C. præstans (excelling). *fl.* nearly as large as those of *Selenipedium grande*; sepals nearly equal, the dorsal one banded green and maroon; petals greenish, suffused rose at base, and spotted maroon along the margins, linear-ligulate, much undulated at base; lip greenish-yellow, with a golden crest, shaped like that of *C. Stonei*, having a very long, channelled stalk; peduncle dark-hairy, five-flowered. Papua, 1884. (G. C. 1887, ii., p. 814; I. H. ser. v. 26.)

C. Reichenbachianum (Reichenbach's). A synonym of *Selenipedium longifolium*.

C. reticulatum (netted). A synonym of *Selenipedium Boissierianum*.

C. Roebelenii (Roebelen's). A synonym of *C. philippinense*.

C. Rothschildianum (Baron F. de Rothschild's). *fl.*, odd sepal yellowish, with blackish longitudinal stripes, and white borders, cuneate-oblong, acute; lateral sepals united into one smaller, shorter body; petals yellowish-green, with dark lines, and with dark blotches at base; lip cinnamon-brown, the mouth bordered ochre, very strong, almost leathery; staminode rising erect from a stout base, and bending down into a narrow, beak-like process. *l.* above 2ft. long, from 2½in. to 3in. wide, glossy green, very strong. Papua, 1887. See Fig. 296. (B. M. 7102.) SYN. *C. Elliottianum* (G. C. 1888, iv., p. 556).

C. Sanderæ (Mrs. Sander's). A provisional name for a plant described as having a large, spear-shaped dorsal sepal coloured crimson, yellow, and green; broad, yellow and red petals; and a long, narrow, yellow lip. Habitat not stated, 1896.

C. Sanderianum (Sander's). *fl.*, sepals yellowish-green, nerved purplish-brown; petals purplish-brown, fading to yellowish, spotted and barred purplish-brown towards the base, where there are some retrorse, purple bristles, linear, twisted, 1ft. to 1½ft. long; lip greenish-bronze, in shape resembling that of *C. Stonei*. Malay Archipelago, 1886. (R. 3.)

C. Schomburgkianum (Schomburgk's). This is described as a "small species, with linear leaves and elegant flowers; it is very near *C. caricinum*." British Guiana, 1890.

FIG. 295. FLOWER OF CYPRIPEDIUM MACRANTHON.

C. spectabile album (white). A variety with pure white flowers. 1897.

C. Stonei candidum (white). *fl.* ivory-white, the petals tinged with rose and the lip with lilac. 1892. The type is a native of Borneo, not Brazil.

Cypripedium—*continued.*

C. S. platytænium (broad-bordered). *fl.*, dorsal sepal white, striped purple; petals whitish outside, spotted and tinted yellow, deep crimson-purple at the tips, the inner surface white, blotched reddish-purple. Sarawak. (F. M. ser. ii. 414; G. C. 1867, p. 1118; R. X. O. ii. 161; W. S. O. iii. 14.)

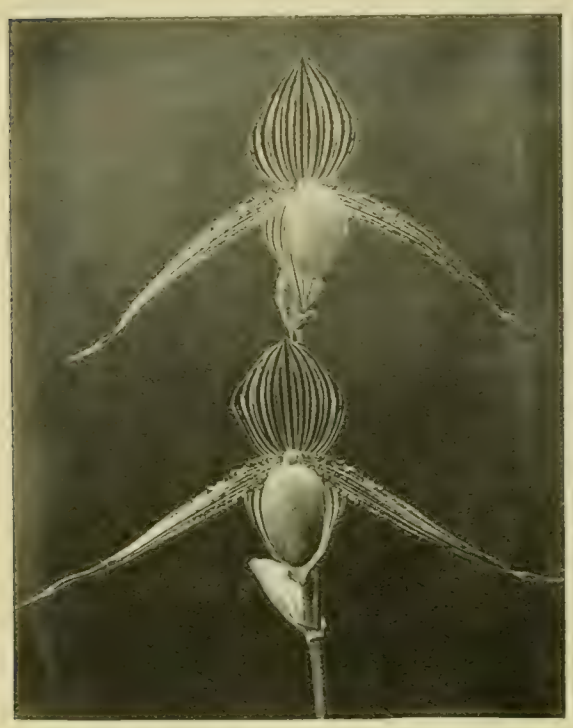

FIG. 296. FLOWER OF CYPRIPEDIUM ROTHSCHILDIANUM.

C. tonquinense (Tonkin). A variety of *C. concolor.*

C. tonsum (shorn). *fl.*, dorsal sepal whitish, with twenty-one green nerves, a small brown blotch on each border inside, and a green disk outside, the lower sepals half as long as the lip; petals oblong-ligulate, acute, nearly free from ciliæ, green, washed with sepia, and spotted with dark brown; lip greenish, the upper surface washed with sepia. *l.* rather narrow, marked as in *C. Dayanum.* Sumatra, 1833. (G. C. 1883, xx., p. 262.)

ventricosum (big-bellied). A variety of *C. macranthon.*

C. venustum Measuresianum (Measures'). *fl.* white and green. 1893.

C. v. pardinum (leopard-marked). *fl.*, sepals and petals white, striped green, the petals also blotched dark chocolate; lip greenish-yellow, marked rose. 1887. Perhaps the finest, and certainly the largest-flowered, variety. (F. M. n. s., t. 51; G. C. 1887, i., p. 382.)

C. Victoriæ-Mariæ (Victoria Maria's). *fl.* 3in. long; sepals green, the dorsal one streaked with red; petals green, with broad purple margins and nerves, 2in. long; lip dull purple, green round the mouth, 2in. long, ¾in. broad; racemes erect, many-flowered, scape 1½ft. high. March. *l.* 1ft. long, 1½in. to 2in. broad, emarginate. Sumatra, 1897. (B. M. 7573.)

C. villosum. Of the numerous varieties of this species the following are all that call for description here. See Fig. 297.

C. v. aureum (golden). *fl.* 6in. across; upper part of the dorsal sepal bright yellow, broadly margined with white. Moulmein. A fine variety.

C. v. Boxallii. *See* **C. Boxallii.**

C. v. Gortoni (Gorton's). *fl.* of a purplish colour. 1893.

C. v. Measuresianum (Measures'). *fl.* having large, dark blotches, as in *C. Boxallii atratum.* 1893.

C. virens (green). *fl.* having the sepals and petals of a deeper and brighter green than in *C. javanicum* (to which this species is closely allied); petals spreading, reflexed beyond the middle; lip of a deeper brown and glossier. North Borneo, 1858. (R. X. O. ii., t. 162.) SYN. *C. javanicum virens.*

C. Volonteanum (Volonte's). *fl.* more brilliantly coloured and larger in all their parts. *l.* shorter, narrower, and more rigid.

Cypripedium—*continued.*

Otherwise closely resembling *C. Hookeræ.* Borneo, 1890. (G. C. 1890, viii., p. 66, under name of *C. Hookeræ Volonteanum.*) The form *giganteum* has flowers twice as large as in the type. 1893. (J. H. 1893, p. 27, f. 4.)

C. Warnerianum (Warner's). A form of *C. barbatum.*

C. Wolterianum (Wolter's). *fl.* like those of *C. Lowii* (which the plant resembles in general appearance), but differing principally in the smaller inferior sepal, in the colour of the basal part of the petals, in the entirely different staminode, and in their smoothness. Habitat not recorded, 1895.

Hybrids. The following is a list of Cypripedium and Selenipedium hybrids up to date, together with their recorded parentage as far as ascertainable.

Abas	*Stoneii* and *villosum* (Veitch).
Acis	*Lawrenceanum* and *insigne Maulei* (Veitch).
Acteus	*Leeanum* and *insigne Sanderæ* (Veitch).
A. de Lacresse	*Curtisii* and *Rothschildianum* (Sander).
Adonis	*hirsutissimum* and *Curtisii* (Ingram).
Adrastus	*Leeanum* and *Boxallii* (Veitch).
Æolus	*philippinense* and *villosum* (Veitch).
Æsculapius	*Lawrenceanum* and *Harrisianum* (R. I. Measures).
Æson	*Druryi* and *insigne* (Veitch).
Ainsworthii	*Roezlii* and *Sedenii.*
A. J. Harrington	*Leeanum superbum* and *œnanthum superbum* (Sander).
albanensis	*Schlimii* and *Sedenii* (Sander).
Albert Hye	Syn. *Lathamianum.*
Albertianum	*Leeanum* var.
albo-purpureum	*Schlimii* and *Dominii* (Veitch).
Alcides	*insigne* and *hirsutissimum* (Sander).
Alcides Cleo	*insigne Chantinii* and *hirsutissimum* (Graves).
Alector	*barbatum Crossii* and *Spicerianum* (Veitch).
Alfred	*philippinense* and *venustum* (Drewett).
Alfred Bleu	*ciliolare* and *insigne Chantinii* (Bleu).
Alfred Bleu	*Crossianum* and *villosum* (Bleu).
Alfred Hollington	*ciliolare* and *philippinense* (Hollington).
Alfred Truffaut	*Harrisianum-vivicans* and *Spicerianum* (Sander).
Alice	*Spicerianum* and *Stoneii* (Drewett).
Alice Gayot	*Harrisianum* and *insigne* (Lebeuf).
Allanianum	*Spicerianum* and *Curtisii* (Pitcher).
Allanianum superbum	*Spicerianum* and *Curtisii* (R. I. Measures).
allertionense	*villosum* and *bellatulum* (Tate).
almos	*villosum aureum* and *insigne* (Ebner).
almum	*barbatum* and *Lawrenceanum* (Cookson).
Alonzo	*Spicerianum* and *Arthurianum pulchellum* (Veitch).

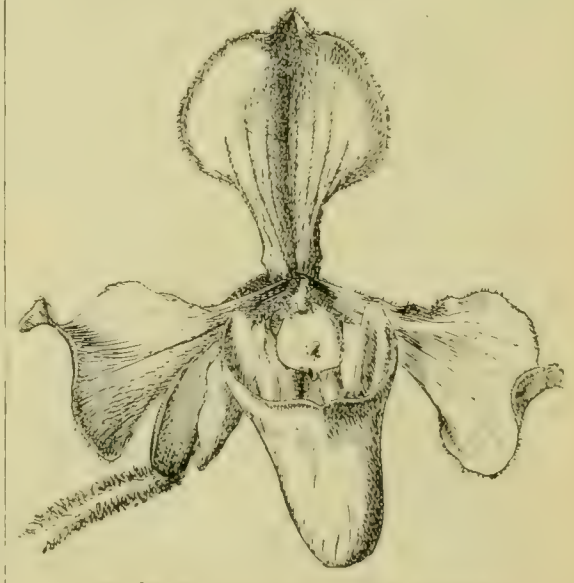

FIG. 297. FLOWER OF CYPRIPEDIUM VILLOSUM.

Cypripedium—*continued.*

Alport	*Lawrenceanum Hyeanum* and *Rothschildianum* (Gratrix).
amabile	*javanico-superbiens* and *Hookeræ* (Seeger).
amabile	*Boxallii* and *Dauthierii* (Page).
amandum	*insigne* and *venustum* (Warner).
Amesiæ	Syn. *Mrs. F. L. Ames.*
Amesianum	*villosum* and *venustum* (Williams).
amethystinum	*villosum* and *Hookeræ* (Bleu).
Amœna	Syn. *Surprise.*
Amphion	*Harrisianum* and *Lawrenceanum* (R. H. Measures).

Cypripedium—*continued.*

Appletoniæ	*Harrisianum* and *ciliolare* (Appleton).
Apuleus	*Lathamianum* and *callosum* (Charlesworth).
Arete	*Spicerianum* and *concolor* (Veitch).
Argo-Arthurianum	*Argus* and *Arthurianum* (R. I. Measures).
Argo-callosum	*Argus* and *callosum* (Cappi).
Argo-Morganiæ	*Argus* and *Morganiæ* (Lawrence).
Argo-Spicerianum	*Argus* and *Spicerianum* (Low).
Argo-Stoneii	*Argus* and *Stoneii* (Cookson)
Ariadne	*Spicerianum* and *selligerum majus* (Statter).

FIG. 298. CYPRIPEDIUM ARTHURIANUM.

Andronicus	Syn. *W. R. Lee* (R. H. Measures).
Angiliæ	*callosum* and *Leeanum* (Martin).
annaerti	*insigne* and *Ashburtoniæ.*
annamense	*Ashburtoniæ expansum* and *Numa* (Statter).
Anna Savage	*Curtisii* and *Chas. Canham* (Kimball).
Annie Ayling	*Curtisii* and *concolor* (Hollington).
Annie Louise	Syn. *Cowleyana.*
Annie Measures	*bellatulum* and *Dayanum* (Sander).
Antigone	*Lawrenceanum* and *niveum* (Veitch).
Anton Jolly	*vernixium* and *Spicerianum* (Jolly).
Aphrodite	*niveum* and *Lawrenceanum* (Veitch).
apiculatum	*Boxallii* and *barbatum* (Veitch).
Apollo	*Stoneii* and *vexillarium* (R. I. Measures).
Arnoldianum	*concolor* and *superbiens* (Pitcher).
Arnoldiæ	*bellatulum* and *superciliare* (Sander).
A. R. Smith	*callosum* and *Druryii* (Sander).
Artemis	*Dayanum* and *Swanianum* (Veitch).
Arthur	*venustum* and *philippinense* (Drewett).
Arthurianum	*insigne* and *Fairieanum* (Veitch). See Fig. 298.
Arthurianum pulchellum	*insigne Chantinii* and *Fairieanum* (Veitch).
Ashburtoniæ	*barbatum* and *insigne* (Cross).
Ashburtoniodes	Syn. *Pitcherianum.*
Ashtonii	*ciliolare superbum* and *selligerum majus* (Lewis).
Ashworthiæ	*Leeanum superbum* and *Spicerianum* (Sander).

Cypripedium—*continued.*

Ashworthianum	*Spicerianum* and *Crossii* (Sander).
Ashworthii	*plunerum* and *Spicerianum* (Sander).
Aspasia	*selligerum majus* and *tonsum* (Sander).
Aspasioides	*selligerum majus* and *Argus* (Rothwell).
Astræa	*philippinense* and *Spicerianum* (Veitch).
Atropos	*Ashburtoniæ expansum* and *purpuratum* (Young).
Atropurpureum	*barbatum nigrum* and *Hookeræ* (Bleu).
Atys	Syn. *Fitchianum.*
Augusta	Syn. *Surprise.*
augustum	*villosum* and *Haynaldianum* (Pitcher).
aurantiacum	Syn. *Crossianum.*
aureum	Syn. *Surprise.*
auricularum	Syn. *vernixium.*
auroreum	*Lawrenceanum* and *venustum* (Cookson).
Aylingii	*niveum* and *ciliolare* (Hollington).
Baconis	*Chlorops* and *Schlimii* (Sander).
Ball, G. S.	Syn. *radiosum.*
barbato-bellum	*barbatum Crossii* and *bellatulum* (Lawrence).
barbato-Charlesworthii	*barbatum Warnerii* and *Charlesworthii* (Lumsden).
barbato-purpurato	*barbatum* and *purpuratum* (Pitcher).
barbato-Veitchii	*barbatum* and *superbiens* (Bleu).
Baron Schröder	*œnanthum superbum* and *Fairieanum* (Veitch).
Bartettii	*insigne Chantinii* and *barbatum* (Baeur).
Bartettii augustum	*barbatum Crossii* and *insigne Kimballiana* (Pitcher).
Basileum	*Druryii* and *Lawrenceanum* (R. H. Measures).
Batalinii	*purpuratum* and *Argus* (Sander).
Beatrice	*Boxallii* and *Lowii* (Drewett).
Beatrice Ashworth	*Leeanum* and *venustum* (Ashworth).
Beechense	*Curtisii* and *superbiens.*
Beeckmanii	*Boxallii* and *bellatulum* (Linden).
Behrensiana	*Io Grande* and *Boxallii* (Sander).
bellato-venustum	*venustum* and *bellatulum* (Lord Burton).
bellato-vexillarium	*bellatulum* and *vexillarium* (Briggs-Bury).
bellinum	*vernixium* and *Harrisianum superbum* (Sander).
Bellona	Syn. *Lathamianum.*
Bellune	*superbiens* and *hirsutissimum* (Vuylsteke).
belmedianum	*Stoneii* and *Farieanum* (Lumsden).
Belus	*Harrisianum nigrum* and *Mastersianum* (Young).
Berenice	*philippinense* and *Lowii.*
bijou	*œnanthum* and *Lawrenceanum* (Ingram).
bingleyense	*Charlesworthii* and *Harrisianum* (Keeling).
Bolerlaerianum	*Dauthierii* and *Harrisianum* (Penwels).
Boltonianum	*calophyllum* and *Leeanum superbum* (Sander).
Bonnyanum	*villosum* and unknown (Bonny).
Bookerii	*ciliolare* and *Spicerianum* (Lewis).
Bosscherianum	Syn. *Eyermanniana.*
Boulemyæ	Syn. *Calypso.*
Boxallio - Rothschildianum	*Boxallii* and *Rothschildianum* (R. I. Measures).
Boyleanum	*Crossianum* and *Harrisianum* (Sander).
Bradshawianum	Syn. *radiosum.*
Bragaianum	Syn. *Godseffianum.*
Brayanum	Syn. *Harrisianum.*
Brennus	*œnanthum superbum* and *Harrisianum* (R. H. Measures).
Brownii	*magnifolium* and *leucorrhodum* (Pitcher).
Brunianum	*Leeanum* and *œnanthum superbum* (Sander).
Bruno	*Spicerianum* and *Leeanum* (Veitch).
Bryan	*philippinense* and *Argus* (Cookson).
Brysa	*reticulatum* and *Sedenii candidulum* (Veitch).
Buchanianum	*Druryii* and *Spicerianum* (Buchan).
Burbidgeanum	*Dayanum* and *concolor.*
Burberryanum	*Boxallii* and *plunerum* (Sander).
burfordiense	*Argus* and *philippinense* (Lawrence).
Burggrenianum	*Dauthierii* and *insigne* (Sander).
Burtonii	*Lowii* and *Hookeræ* (Burton).
Cahuzac	*Spicerianum* and *Haynaldianum* (Sander).
Calanthum	*barbatum Warnerii* and *Lowii* (Veitch).
caligare	*venustum* and *Dayanum* (Veitch).
Calliope	*callosum* and *Lathamianum* (Clarke).

Cypripedium—*continued.*

callo-bellum	*callosum* and *bellatulum* (Lawrence).
calloso-Argus	*callosum* and *Argus.*
calloso-barbatum	*callosum* and *barbatum* (Charlesworth).
calloso-niveum	*callosum* and *niveum* (R. H. Measures).
calloso-Rothschildianum	*callosum* and *Rothschildianum* (Fowler).
calophyllum	*barbatum* and *venustum* (Williams).
calurum	*longifolium* and *Sedenii* (Veitch).
Calypso	*Spicerianum* and *Boxallii* (Veitch).
Cambridgeanum	*Harrisianum* and *insigne punctatum violaceum* (R. I. Measures).
Captain Holford	*superbiens* and *hirsutissimum* (Veitch).
Captain Lendy	*Boxallii* and *Charles Canham* (Ingram).

FIG. 299. FLOWER OF CYPRIPEDIUM CARDINALE.

cardinale	*Sedenii* and *Schlimii albiflorum* (Veitch). See Fig. 299.
Cardinal-Schlim	*cardinale* and *Schlimii* (R. I. Measures).
Carl Peeters	Syn. *Chas. Richman.*
Carnusianum	*Haynaldianum* and *Spicerianum* (Carnuse).
Carrierii	*superbiens* and *venustum* (Carrier).
Cassiope	*venustum* and *Hookeræ* (Seeger).
Castleanum	*hirsutissimum* and *superbiens* (Sander).
Cecilia	Syn. *Maynardii.*
Celeus	Syn. *nitens.*
Celia	*Spicerianum* and *Lowianum* (Low).
Ceres	*hirsutissimum* and *Spicerianum* (Drewett).
Chamber-Leeanum	*Chamberlainianum* and *Leeanum* (Van Gert).
Chantino-ciliolari	*insigne Chantinii* and *ciliolare* (Bleu).
Chantino-Reignerii	*insigne Chantinii* and *concolor Reignerii* (Bleu).
Chapmanii	*Curtisii* and *bellatulum* (R. I. Measures).
Chapmanii magnificum.	*bellatulum* and *Curtisii* (R. I. Measures). See Fig. 300.
Charles Canham	*villosum* and *superbiens* (Veitch).
Charles Gorndoin	*insigne Chantinii* and *vernixium* (Jolibois).
Charles Reffold	*œnanthum superbum* and *Spicerianum* (Ingram).
Charles Richman	*bellatulum* and *barbatum* (Richman).
Charles Steinitz	*philippinense* and *Lawrenceanum* (Sander).
Charlesianum	*Sallierii* and *Leeanum superbum.*
Charpinianum	*Spicerianum* and *Morganiæ.*
chelsiense	*Lowii* and *barbatum Warnerii* (Bull).

Cypripedium—*continued.*

Chillianum	*Gouverianum* and *Rothschildianum* (Schofield).
chloroneuron	*barbatum* and *venustum* (Warner).
Chlorops	*longifolium Hartwegii* and *caricinum* (Sander).
chrysocomes	*caudatum* and *conchiferum* (Seeger).
cilio-villosum	*ciliolare* and *villosum* (Lewis).
claptonense	Syn. *nitens.*
Claudii	*Spicerianum* and *vernixium.*
Clement Loury	*Harrisianum* and *insigne Chantinii* (Jolibois).
Clement Moore	*Dauthierii* and *Leeanum* (Sander).
Cleola	*reticulatum* and *Schlimii albiflorum* (Veitch).
Cleopatra	*Hookeræ* and *œnanthum superbum* (Winn).
Clinkaberryanum	*philippinense* and *Curtisii.*
Clonius	*caudatum Lindenii* and *conchiferum* (Veitch).
Clothilde Moens	*Leeanum superbum* and *Haynaldianum* (Moens).

FIG. 300. FLOWER OF CYPRIPEDIUM CHAPMANII MAGNIFICUM.

Clotho	*Pollettianum* and *Boxallii atratum* (Young).
Clovenfordsi	*superbiens* and *philippinense* (Thompson).
Cobbiana	*Lawrenceanum* and *Sallierii* (Cobb).
Colmanii	Syn. *Eismannianum.*
Comet	*Stoneii* and *superciliare* (Sander).
compactum	*Sedenii candidulum* and *calarum* (Ingram).
Comte Andre de Germiny	*Swanianum* and *Rothschildianum* (Sander).
Comus	*insigne maximum* and *Swanianum* (Graves).
conchiferum	*caracinum* and *longifolium* (Bowering).
concinnum	*villosum* and *purpuratum* (Bull).
conco-bellatulum	*concolor* and *bellatulum* (Statter).
conco-callosum	*concolor* and *callosum* (R. H. Measures).
conco-Lawre	*concolor* and *Lawrenceanum* (Lawrence).
conco-villosum	*concolor* and *villosum* (Sander).
conspicuum	*Harrisianum* and *villosum* (Swan).
Constableanum	*Farieanum* and *Dayanum* (Pitcher).
Constance	*Curtisii* and *Stoneii* (Drewitt).
Cooksonii	Syn. *almum.*
Coppianianum	*Sedenii* and *conchiferum* (Sander).
corbeillense	*Bullenianum* and *insigne* (Maron).
Corndeanii	*Lawrenceanum* and unknown (Swainburn).

Cypripedium—*continued.*

Corningianum	Syn. *Youngianum.*
Cowleyana	*Curtisii* and *niveum* (Tautz).
Cravenianum	*bellatulum* and unknown (Schofield).
Creon	*Harrisianum superbum* and *œnanthum superbum* (Veitch).
Crethus	*Argus* and *Spicerianum* (Veitch).
Crossianum	*insigne* and *venustum* (Ashburton).
Cumea	*longifolium Hartwegi* and *Sedenii* (Graves).
Cupid	*Cardinale* and *Lindleyanum* (Veitch)
Cybele	*Druryi* and *Lawrenceanum* (Pitcher).
Cydippe	*superbiens* and *Hookeræ* (Veitch).
Cymatodes	*Curtisii* and *superbiens* (R. H. Measures).
Cyris	*Bozallii atratum* and *Argus* (Cookson).
Cythera	*Spicerianum* and *purpuratum* (R. H. Measures).
Dædalus	*insigne punctatum violaceum* and *vexillarium superbum* (Young).
Daisyæ	*Lowii* and *œnanthum superbum* (Graves).
Dauthierii	*barbatum* and *villosum* (Van Houtte).
Davisianum	Syn. *Cyris.*
Dayano-Curtisii	*Dayana* and *Curtisii* (Graves).
De Bosscherianum	Syn. *Eyermanniana.*
decorum	*Sallierii Hyeanum* and *Lawrenceanum* (Hye).
Deedmanianum	*Spicerianum* and *Chamberlainianum* (Latham).
delicatum	*Dayanum* and *barbatum Warnerii* (Drewitt).
Dennisianum	*superbiens* and *selligerum majus* (Linden).
Desboisianum	*venustum* and *Bozallii atratum* (Vervaet).
De Witt Smith	*Spicerianum* and *Lowii* (Low).
Diana	Syn. *Eyermanniana.*
Dibdin	Syn. *Cyris.*
Diolare	*villosum* and *venustum* (Cookson).
discolor	*venustum* and unknown (Williams).
Dominii	*caracinum* and *caudatum* (Veitch).
Dominii albiflorum	*caracinum* and *caudatum Wallisii* (Veitch).
Donatianum	*Harrisianum* and *insigne Wiottii* (Sander).
Doncasterianum	*hirsutissimum* and *callosum* (Sander).
Doris	*venustum* and *Stoneii* (Cookson).
Driherianum	Syn. *Leander.*
Dr. Ryan	Syn. *Deedmanianum.*
Drurio-Hookeræ	*Hookeræ* and *Druryi* (Veitch).
Drurio-Lawrenceanum	*Lawrenceanum* and *Druryi* (Veitch).
Drurio-villosum	*villosum* and *Druryi* (Veitch).
Dubium	*Bozallii* and *venustum.*
Duchess of Sutherland	*Youngianum* and *Rothschildianum* (Sander).
E. Ashworth	*plunerum* and *Spicerianum* (Sander).
Echo	*Hookeræ* and *insigne Chantinii* (Graves).
Edithæ	*conchiferum* and *Schlimii albiflorum* (Sander).
Edith Winn	*Stoneii* and *purpuratum* (Winn).
Edwardii	*Fairieanum* and *superbiens* (Pitcher).
Edward Jolibois	*insigne Maulei* and *barbatum* (Jolibois).
E. Holt	*Curtisii* and *Præstans* (Sander).
Eismannianum	*Boxallii* and *Harrisianum* (Seeger).
Electra	Syn. *œnanthum.*
elegans	Syn. *Harrisianum.*
Elinor	*selligerum majus* and *superbiens* (Drewitt).
Elizabethiæ	*Lawrenceanum* and *Parishii* (R. H. Measures).
Elsteadianum	*conchiferum* and *grande* (Ingram).
Empress	*Cardinale* and *Sedenii albiflorum* (Ball).
Endymion	*barbatum* and *Mastersianum* (Young).
enfieldiensis	*Lawrenceanum* and *Hookeræ* (Hollington).
Englehardtiæ	Syn. *Leeanum.*
Enid	*bellatulum* and *Spicerianum* (Rothschild).
Ensign	*Harrisianum* and *barbatum biflorum* (Winn).
Ephialtes	*insigne Chantinii* and *aurorum* (Pitcher).
Erato	*Sallierii* and *hirsutissimum.*
Eros	*barbatum Warnerii* and *Charles Canham* (Wills).
Erycina	Syn. *Pitcherianum.*
Etienne Jolibois	*insigne Maulei* and *hirsutissimum* (Jolibois).
Etiocle	Syn. *Surprise.*
Eucharis	*insigne Chantinii* and *Lawrenceanum.*
Euphrosyne	Syn. *Adriadne.*
Euryades	*Leeanum* and *Boxallii* (Veitch).

Cypripedium—*continued.*

Euryale	*Lawrenceanum* and *superbiens* (Veitch).
Euryandrum	*barbatum* and *Stoneii* (Veitch).
Eurydice	*Hookeriæ* and *Spicerianum* (Graves).
Eurydice	*hirsutissimum* and *Leeanum* (Vuylsteke).
Eurylochus	*ciliolare* and *hirsutissimum* (Veitch).
Euterpe	*venustum* and *philippinense* (Statter).
Evenor	*concolor* and *Argus* (Veitch).
Excelsior	Syn. *Buchanianum* (Hye).
Excelsior	*Rothschildianum* and *Harrisianum* (Statter).
Eyermanniana	*barbatum grandiflorum* and *Spicerianum* (Sander).
Eyermanniana Diana	*barbatum superbum* and *Spicerianum magnificum* (R. H. Measures).
Eyermanniana Hermione	*barbatum Warnerii* and *Spicerianum* (Young).
Fairieano-Lawrenceanum	*Lawrenceanum* and *Fairieanum* (R. H. Measures).
Fairy Queen	*Curtisii* and *Druryii* (Sander).
Fascinator	Syn. *Ceres*.
Fausianum	*Dauthierii* and *calophyllum* (Sander).
Favager	*Charlesworthii* and *concinnum* (Rehder).
Felix Faure	*Godefroyæ* and *callosum* (Dellamagne).
Felix Jolibois	Syn. *œnanthum*.
festum	*chloroneuron* and *barbatum Warnerii* (Seeger).
Figaro	*Spicerianum* and *œnanthum* (Seeger).
Finetianum	*philippinense* and *ciliolare* (Seeger).
Finetianum	*Cardinale* and *caudatum* (Finet)
Fitchianum	*Hookeræ* and *barbatum* (Williams).
Flamingo	Syn. *Calypso*.
Flora	Syn. *Calypso*.
Fordianum	*Stoneii* and *callosum* (Sander).
Fortuna	*Hookeræ* and *callosum* (Young).
Fournierianum	*insigne Maulei* and *Lawrenceanum* (Sander).
Fowlerianum	*Harrisianum* and *bellatulum* (Sander).
François Peeters	Syn. *Charles Richman*.
Fraserii	*hirsutissimum* and *barbatum* (Veitch).
Frau Ida Brandt	*Io grande* and *Youngianum* (Sander).
Frederico Nobile	*Boxallii* and *Morganiæ* (Seeger).
F. S. Roberts	*niveum* and unknown (Low).
fulgens	*marmarophyllum* and *Hookeræ* (Sander).
Furzianum	*callosum* and *hirsutissimum* (Sander).
Gabrali	*orphanum* and *Dauthierii* (Gabral).
Galatea	Syn. *œnanthum*.
gandavense	*barbatum* and *Swanianum*.
Garbari	*Lawrenceanum* and *Rothschildianum* (Sander).
Garret A. Hobart	*Lathamianum* and *insigne Chantinii* (Roebling).
Gaskelliana	Syn. *Niobe*.
gemmiferum	*Hookeræ* and *purpuratum* (Veitch).
Genesa	*Sallierii Hyeanum* and *Lawrenceanum Hyeanum* (R. I. Measures).
George Kettle	*Dayanum* and *superbiens* (Kettle).
George Truffaut	*ciliolare* and *Stoneii* (Sander).
Georgianum	*superbiens* and *niveum* (Graves).
Germain Sciller de Gisors	Syn. *œnanthum*.
Germinyanum	*villosum* and *hirsutissimum* (Veitch).
Gertrude	Syn. *Miss L. Fowler*.
Gertrude Hollington	*ciliolare* and *bellatulum* (Hollington).
G. H. Rodgers	*insigne punctatum violaceum* and *superbiens* (Williams).
Gibezranum	Syn. *Measuresianum*.
giganteum	*Harrisianum* and *Sallierii Hyeanum* (Hye).
gigas	*Lawrenceanum* and *Harrisianum* (Ingram).
Gillianum	Syn. *Hera*.
gloriosum	Syn. *gigas*.
Godefroyæ	*bellatulum* and *niveum* (also nat. hyb.) (Strickland). See Fig. 301.
Godseffianum	*Boxallii* and *hirsutissimum* (Cookson).
Goultenianum	*Curtisii* and *callosum* (Goulten).
Gowerianum	*Curtisii* and *Lawrenceanum* (Sander).
gracile	*Haynaldianum* and *Swanianum* (Ingram).
grande	*Roezlii* and *caudatum* (Veitch).
Gravesiæ	*Argus* and *niveum* (Graves).
Gravesianum	*Lathamianum* and *Leeanum* (Sander).
Greyanum	*Druryii* and *ciliolare* (Pitcher).
G. S. Ball	Syn. *radiosum*.
Hardyanum	Syn. *macrochilum*.
Harri-Leeanum	*Harrisianum* and *Leeanum* (Clarke).
Harri-Sander	*Harrisianum* and *Sanderianum* (Clarke).
Harrisianum	*villosum* and *barbatum* (Veitch).
Harrisi-froyæ	*Harrisianum* and *Godefroyæ* (Lawrence).

Cypripedium—*continued.*

Harryanum	*Stoneii* and *Leeanum* (Backhouse).
Hayetti	Syn. *Ledouxiæ*.
Haynaldo-bellatulum	*Haynaldianum* and *bellatulum* (Clarke).
Haynaldo-Chamberlainianum	*Haynaldianum* and *Chamberlainianum* (Ashworth).
H. Ballantinæ	*purpuratum* and *Fairieanum* (Veitch).
Hebe	Syn. *Alice*.
Hecla	*superbiens* and *Swanianum* (Ingram).
Heloise Mantin	*gemmiferum* and *Boxallii* (Martin).
Helvita	*Chamberlainianum* and *philippinense* (Leeman).
H. E. Mojan	*Hookeræ volontianum* and *Harrisianum* (R. H. Measures).
Henri van der Straten	*Mrs. Canham* and *Leeanum* (Sander).
Henry Graves, jun.	*Lawrenceanum* and *Marshallianum* (Graves).
Hera	*Boxallii* and *Leeanum* (R. H. Measures).
Hermione	Syn. *Eyermanniana*.

FIG. 301. FLOWER OF CYPRIPEDIUM GODEFROYÆ LEUCOCHILUM.

Hero	*villosum* and *Boxallii*.
Hiero	*Chamberlainianum* and *Lawrenceanum* (Veitch).
highfieldense	*Lawrenceanum* and *Druryii* (Barton).
hirsuto-Sallierii	*hursutissimum* and *Sallierii* (Lawrence).
hirsuto-villosum	*hirsutissimum* and *villosum* (Cappi).
Hobsonii	*philippinense* and *callosum* (Hollington).
Hollidayanum	*concolor* and *almum* (Sander).
Hookerii-Veitchii	*Hookeræ* and *superbiens* (Williams).
Hornerii	Syn. *Cyris*.
Hornianum	*superbiens* and *Spicerianum* (Sander).
Hurrellianum	*Argus* and *Curtisii* (Pitcher).
Huybrechtsianum	Syn. *Ceres*.
hybridum	*villosum* and *barbatum*.
Iago	*Dayanum* and *villosum* (Wrigley).
I'Ansoni	*Morganiæ* and *Rothschildianum* (Low).
Ianthe	*Harrisianum* and *venustum* (Veitch).
imperatrix	*Ashburtoniæ expansum* and *calophyllum* (Sander).
imperiale	Syn. *Madam Jules Hye*.
Indra	*callosum* and *villosum* (R. I. Measures).
Ino	*Haynaldianum* and *Mrs. Canham* (Grey).
insigne-tonsum	*insigne* and *tonsum* (Sander).

Cypripedium—*continued.*

inspirator	Syn. *Madam Jules Hye.*
intermedium	Syn. *hybridum.*
inversum	*villosum* and *superbiens.*
Io	*Argus* and *Lawrenceanum* (Sander).
Iocasta	*Haynaldianum* and *insigne Chantinii* (Veitch).
Io grande	*Argus* and *Lawrenceanum* (Sander).
Ionides	Syn. *Behrensianum.*
Io-Spicerianum	*Io* and *Spicerianum* (Robins).
Iris	*javanico-superbiens* and *ciliolare* (Bleu).
Isabellicæ	*Spicerianum* and *niveum* (Williams).
Jacobianum	*Crossianum* and *bellatulum* (Le Roy).
James Buckingham	*enfieldiense* and *bellatulum* (Hollington).
Jamesonianum	*Leeanum* and *Arthurianum* (Statter).
Janet	*Spicerianum* and *glandaliferum* (Veitch).
Janet Ross	*Svanianum* and *Harrisianum* (Ross).
Janus	*Spicerianum* and *vexillarium* (R. I. Measures).
javanico-insigne	*javanicum* and *insigne* (Pitcher).
javanico-Spicerianum	*javanicum* and *Spicerianum* (Page).
javanico-superbiens	*javanicum* and *superbiens* (Bleu).
J. Bartels	*Boxallii* and *callosum* (Sander).
J. Coles	*Godefroyæ leucochilum* and *Dayanum* (R. H. Measures).
Jeanette	*niveum* and *Leeanum* (Charlesworth).
Jensenianum	*hirsutissimum* and *vexillarium* (Sander).
J. Gurney Fowler	*Godefroyæ* and *barbatum* (Low).
J. H. Berry	*Harrisianum superbum* and *concolor* (Sander).
J. Howes	*Sallierii* and *villosum* (Cobb).
J. H. Veitch	*Curtisii* and *Stoneii platytænium* (Veitch).
James K. Polk	*nitens* and *Chamberlainianum* (*Rœbling*).
John Carder	*Selligerum majus* and *hirsutissimum* (Sander).
Johnsonii	*nitens magnificum* and *Lawrenceanum* (Sander).
Jolien Coffegnez	Syn. *Ianthe.*
Joseph Donat	*Ashburtoniæ* and *Spicerianum* (Sander).
Josephianum	*Druryii* and *javanico-superbiens* (Pitcher).
Josephine Jolibois	Syn. *œnanthum.*
Juno	*Fairieanum* and *callosum* (Cookson).
Jupiter	Syn. *Godseffianum.*
Kaloc	*barbatum* and *Argus* (R I. Measures).
Kerchovianum	*Curtisii* and *barbatum.*
Kimballianum	*Rothschildianum* and *Dayanum* (nat. hyb.).
Kirchoffianum	*Dauthierii* and *Spicerianum* (Seeger).
Kramerianum	*œnanthum* and *villosum* (Sander).
Krishna	*insigne* and *tonsum* (Graves).
Krousianum	*Spicerianum* and *Crossianum* (Pitcher).
Lachesis	*Crossianum* and *marmarophyllum* (Young).
Lachmee	*ciliolare* and *superbiens* (R. I. Measures).
Lady Hutt	*insigne* and *Fitchianum* (Swinburne).
Lady Isabel	*Rothschildianum* and *Stoneii* (Sander).
Lady Maple	*Youngianum* and *Gowerianum* (Sander).
Lady Wimborne	Syn. *Leander.*
Laforcadei	*barbatum* and *insigne punctatum violaceum Godefroyæ.*
La France	*nitens* and *niveum* (Seeger).
La Nymphe	*œnanthum* and *Dauthierii* (Ingram).
Lathamianum	*Spicerianum* and *villosum* (Latham).
latiflorum	*venustum* and *philippinense* (Statter).
Laucheanum	*barbatum* and *insigne amabile* (Sander).
Lauriæ	*villosum* and *superciliare* (Le Doux).
Laure-bel	*Lawrenceanum* and *bellatulum* (Lawrence).
Lawre-concolor	*Lawrenceanum* and *concolor* (Sander).
Lawre-venustum	*Lawrenceanum* and *venustum.*
Lawrenceano-Curtisii	*Lawrenceanum* and *Curtisii* (Bleu).
Lawrenceano-Druryii	*Lawrenceanum* and *Druryii* (Veitch).
Lawrenceano-Fairieanum	*Lawrenceanum* and *Fairieanum* (R. H. Measures).
Leander	*Leeanum* and *villosum* (R. H. Measures).
Lebandyanum	*philippinense* and *Haynaldianum* (Page).
Leda	*Harrisianum* and *venustum* (Bowering).
Ledouxiæ	*callosum* and *Harrisianum* (Le Doux)
Leeanum	*insigne* and *Spicerianum* (Lawrence). See Fig. 302.
Leeanum-Galatea	*Leeanum* and *Galatea* (Sander).

Cypripedium—*continued.*

Leeanum-Morganiæ	*Leeanum* and *Morganiæ* (R. I. Measures).
Lemoinierii	*calurum* and *porphyreum* (Sander).
Leo	Syn. *Lathamiana* (Hye).
Leo	*Wallertianum* and *insigne Chantinii.*
Leoniæ	*insigne Chantinii* and *callosum* (Leon).
Leonides	Syn. *St. Mark.*
Leopoldianum	*Leeanum superbum* and *insigne* (Hye).
Leopoldianum	*Sallierii Hyeanum* and *hirsutissimum* (Vuylsteke).
lepidum	Syn. *Tautzianum.*
leucorrhodum	*Rœzlii* and *Schlimii albiflorum* (Veitch).
Leysenianum	Syn. *Chas. Richman.*
Lily	*niveum* and *bellatulum* (Keeling).
Lily Measures	*niveum* and *Dayanum* (R. H. Measures).
Littleanum	*Lawrenceanum* and *Dayanum* (nat. hyb.) (Little).
Lobengula	*insigne Chantinii* and *Harrisianum.*
Loewegrianum	*Spicerianum* and *Io grande* (Sander).
Loochrystianum	*Harrisianum* and *Hookeræ* (Vuylsteke).
Lord Derby	Syn. *W. R. Lee.*
Louisiæ	*Leeanum* and *Ashburtoniæ* (Le Doux).
Louryanum	*Ashburtoniæ* and *vernixium* (Sander).
Louryi	*insigne Chantinii* and *Harrisianum.*
Lowii-superbiens	*Lowii* and *superbiens* (Lawrence).

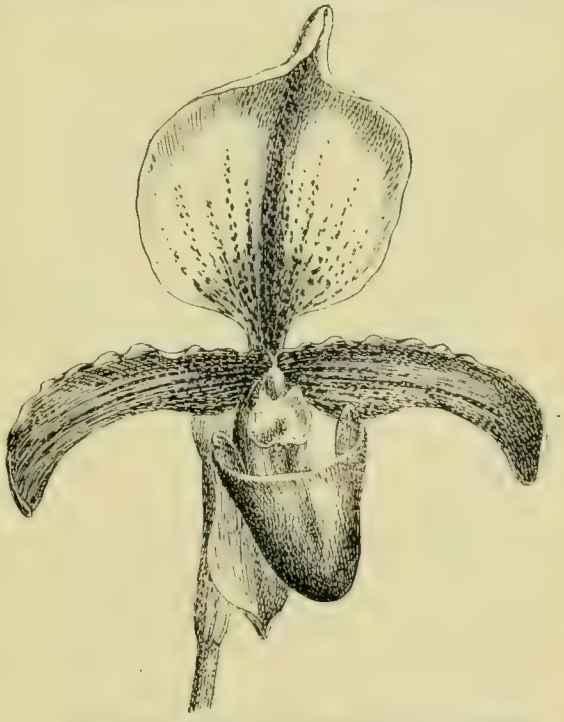

FIG. 302. FLOWER OF CYPRIPEDIUM LEEANUM SUPERBUM.

lucidum	*Lowii* and *villosum* (R. I. Measures).
Lucie	*Lawrenceanum* and *ciliolare.*
Lucienianum	Syn. *nitens.*
L'unique	*Lindleyanum* and *Schlimii albiflorum* (Ingram).
luridum	*Lawrenceanum* and *villosum* (Pitcher).
lutescens	*Spicerianum* and *javanicum* (Pitcher).
Lynchianum	*Spicerianum* and *selligerum majus* (Sander).
Mabeliæ	Syn. *W. R. Lee.*
Macfarlainei	*calophyllum* and *Spicerianum* (Sander).
MacNabbianum	Syn. *conco-callosum.*
macrochilum	*Roezlii* and *caudatum Lindenii* (Veitch).
macrochilum giganteum	*Grande* and *caudatum Lindenii* (Veitch).
macropterum	*Lowii* and *superbiens* (Veitch).

Cypripedium—*continued.*

maculatum ..... *tonsum* and *Leeanum* (Sander).
Madame Barbary ..... *Lawrenceanum* and *tonsum* (Jolibois).
Madame Cappi ..... *Spicerianum* and *Dauthierii* (Cappi).

Zeus	*callosum* and *ciliolare* (R. I. Measures).
Zuriago	*œnanthum superbum* and *Chamberlainianum* (Leeman).

CYRILLA (of L'Héritier). A synonym of **Achimenes** (which *see*).

CYRTANDRA (from *kyrtos*, curved, and *aner*, *andros*, a male; alluding to the curved filaments of the perfect stamens). ORD. *Gesneraceæ*. A genus embracing about sixty species of stove trees, shrubs, or sub-shrubs, natives of the Malayan Archipelago and the Pacific Islands. Flowers often whitish or yellowish, fascicled, capitate, or cymose in the axils; calyx free, five-cleft or somewhat five-parted; corolla sub-bilabiate; perfect stamens two; staminodes two or three, small; bracts small, or the outer ones ample. Leaves opposite, one often smaller, or by abortion nearly alternate. For culture of the two species introduced, *see* **Agalmyla.**

C. pendula (pendulous). *fl.* sessile; calyx brownish, ten to eleven lines long; corolla white, dotted purple on the lower side of the inflated part, 1½in. long, sub-equally five-lobed; peduncle about 6in. long, bent down. *l.* opposite, on long petioles, elliptic or elliptic-lanceolate, acute at apex, acute or sub-cordate at base, blotched grey above. Stem short and stout. Java, 1883.

C. Pritchardii (Pritchard's). *fl.* white, small, disposed in pedunculate, axillary, three-flowered cymes. *fr.* white, ovoid. *l.* petiolate, elliptic, obtusely toothed, acute at both ends, 5in. to 6in. long, 2in. to 2½in. broad. Fiji, 1837.

CYRTANDRACEÆ. Included under **Gesneraceæ** (which *see*).

CYRTANTHUS. SYNS. *Cyphonema, Eusipho, Gastronema, Monella,* and *Timmia.* According to J. G. Baker, this genus embraces about a score species, natives of the Cape of Good Hope and Angola. Flowers usually red or white, with green stripes, erect or pendulous; perianth tube twice or three times as long as the oblong segments; spathe-valves two to four, green, lanceolate; peduncle hollow. Leaves persistent, linear or lorate. To the species described on p. 428, Vol. I., the following should be added:

C. Galpini (Galpin's). *fl.*, perianth of a beautiful red tinged with yellow; tube cylindrical at base, broadly funnel-shaped above the middle; segments twice or thrice as long as the tube; scape very slender, one-flowered. August. Bulb ovoid, pale. Transvaal, 1892.

C. Huttoni (Hutton's). *fl.* six to eight in an umbel; perianth pale red, about 1in. long, the tube curved, narrowly funnel-shaped, twice as long as the segments; pedicels ½in. to 1in. long; peduncle 1ft. long. May. *l.* lorate, 1ft. long, ½in. to ¾in. broad. Cape Colony, 1864. (B. M. 7488.)

C. hybridus (hybrid). *fl.* light orange-scarlet or bright rosy-carmine. In general appearance this bigeneric hybrid between *C. sanguineus* and *Vallota purpurea* resembles the latter parent, but the perianth tube is bent forward and rather abruptly dilated in the throat, and the segments are rather narrower. The stamens are short, and the upper ones are curved downwards exactly as in *C. sanguineus.* 1885.

C. intermedius (intermediate). A garden hybrid between *C. Mackenii* and *C. angustifolius.*

C. lutescens, of gardens. A synonym of *Anoiganthus breviflorus.*

C. lutescens Cooperi (Cooper's). *fl.* more numerous than in the type; perianth segments more spreading; pedicels and spathe-valves longer. (B. M. 5374, under name of *C. lutescens.*)

C. Mackenii is the correct spelling of *C. M'Kenii.*

C. O'Brieni (O'Brien's). *fl.* bright scarlet, about eight in an umbel; perianth 1½in. long. *l.* contemporary with the flowers, linear. South Africa, 1894. An interesting species, intermediate between *C. angustifolius* and *C. Macowani.*

C. odorus (odorous). *fl.* bright red, fragrant, 2in. long, four to ten in an umbel; peduncle slender, 6in. to 12in. long. July and August. *l.* two or three, linear, straight, 1ft. long. Bulb ovoid, 1½in. in diameter. 1818. (B. R. 503.)

C. parviflorus (small-flowered). *fl.* ten to twelve in an umbel; perianth bright scarlet, sub-cylindric, 1in. to 1¼in. long; scape terete, as long as the leaves. January. *l.* produced with the flowers, linear, 1ft. long. Port Elizabeth, 1891. SYN. *Monella parviflora.*

Cyrtanthus—*continued.*

C. Smithianus (Smith's). *fl.* white, striped with green or reddish-brown, 3½in. to 4in. long; tube gradually dilated to a throat 1in. in diameter; umbel one- or two-flowered; peduncle 6in. long. May. *l.* two or four, linear, spirally twisted, 6in. to 9in. long. Kaffraria, 1876.

C. spiralis (spiral). *fl.* tubular, pendent, disposed in umbels, the six corolla segments of a bright red and almost triangular. *l.* long, ribbon-like, spirally twisted, glaucous-green. South Africa. A rare and very curious species. (G. C. 1897, ii., p. 303, f. 89.)

C. Tuckii (Tuck's). *fl.* yellowish at the base, passing upwards into blood-red, 1½in. to 2in. long, ten to twelve in an umbel; perianth tube curved, narrowly funnel-shaped, the segments oblong, ¼in. long; peduncle 1ft. to 1½ft. long. July. *l.* two, linear, 1ft. to 1½ft. long. Bulb 1½in. in diameter, the neck produced. Cape Colony, 1884.

CYRTANTHUS (of Schreber). A synonym of **Posoqueria** (which *see*).

CYRTOCERAS. The correct name of *C. multiflorum* is *Hoya multiflora.*

CYRTOCHILUM. This genus is now included, by Bentham and Hooker, under *Oncidium.* To the species described on p. 428, Vol. I., the following should be added:

C. detortum (distorted). *fl.*, sepals light brown, cuneate-oblong, acute, wavy, the odd one with a little yellow at the upper part; petals yellow, spotted brown, wavy; lip three-cleft, the side laciniæ spreading, triangular, and the mid-lacinia ligulate, acute; peduncle very strong, twisted. *l.* broad-oblong, acute, light green.

C. lutescens (yellowish). *fl.*, dorsal sepal dark brown, with a yellow, recurved margin, much waved at the edge, the stalk very short, with auricles, the lateral sepals greenish-brown, acute, longer-stalked; petals with a crisped, yellow limb; lip dark greenish, ligulate, short, the anterior part purple; column greenish, orange, and brown. 1837.

C. micranthum (small-flowered). *fl.* smaller than in *C. maculatum* (which this species resembles); sepals and petals greenish, spotted; lip white, with two brown blotches, yellow on the anterior part. Brazil, 1836.

CYRTOGONIUM. *See* **Acrostichum.**

CYRTOMIUM. *See* **Aspidium.** *C. caryotideum* is a variety of *A. falcatum*, and *C. Fortunei* is identical with *A. f. Fortunei.*

CYRTONEMA. A synonym of **Kedrostis** (which *see*).

CYRTOPERA (from *kyrtos*, curved, and *pera*, a small sack: in allusion to the sack-like appendage to the lip). ORD. *Orchideæ.* A genus embracing a few species of stove or greenhouse, terrestrial Orchids, mostly natives of Asia and Africa, nearly allied to *Cyrtopodium*, from which they differ in the lateral sepals being wider at the base and connate with the foot of the column, and in the simple inflorescence. Flowers generally showy, in erect spikes springing from the root. Leaves long, thin, plaited, dark green. Stems short or elongated. For culture, *see* **Cyrtopodium.**

C. flava (yellow). The correct name of *Cyrtopodium flavum.*

C. flexuosa (bending). *fl.* white, with purple spots and a yellow blotch on the lip; scape 1ft. long, flexuous. *l.* four, linear, flaccid, nearly 1ft. long. Pseudo-bulbs ovoid, ¾in. long. Eastern tropical Africa, 1894.

C. papillosa (papillose). *fl.* yellow, with some purplish-brown on the side lobes of the lip, about 1in. across; scape 2ft. high, bearing a few flowers. *l.* lanceolate, about 1ft. long. Natal, 1893. (L., t. 371.)

C. Regnieri (Regnier's). *fl.* yellow, large; sepals and petals falcate-lanceolate, acute; lip oblong-lanceolate, with a wide, blunt angle on each side at the middle; spur conical; raceme on a tall peduncle arising from the side of the leafy shoot. *l.* oblanceolate. Cochin China, 1886.

C. sanguinea (blood-coloured). The correct name of *Cyrtopodium sanguineum.*

C. Woodfordii (Woodford's). *fl.* yellow, with a purple lip; petals oblong, connivent, shorter than the acute sepals; scape radical, 1½ft. to 3ft. high, many-flowered. *l.* lanceolate, plicate, 8in. to 18in. long, spreading. Stem fusiform, fleshy. Tropical America, 1819. SYN. *Cyrtopodium Woodfordii* (B. M. 1814; B. R. 1503).

C. plicata and *C. squalida* are in cultivation at Kew.

CYRTOPODIUM. This genus embraces upwards of a score species of stove, terrestrial Orchids, inhabiting tropical Asia, Africa, and America. Sepals free, spreading, sub-equal, or the lateral ones broader at base and more or less decurrent into the foot of the column; petals similar to the dorsal sepal, but rather broader and shorter; lip affixed to the base of the column, the chin more or less prominent, the lateral lobes rather broad, the middle one rounded, entire, two-lobed, or crisped-toothed. Leaves long. To the species described on p. 428, Vol. I., the following should be added. *See also* **Cyrtopera** (which is included hereunder by Bentham and Hooker).

C. Aliciæ (Alicia's). *fl.* 1½in. in diameter; sepals and petals green, with brown spots; lip white, with crimson spots, three-lobed, the crest yellow; scape tall, branched, many-flowered. *l.* long, linear-lanceolate. Pseudo-bulbs large, fusiform. Brazil, 1893. (L. viii., t. 371.)

C. Andersonii cardiochilum (cordate-lipped). *fl.* bright yellow, tinged green, nearly 2in. across; lip recurved, the front lobe concave; raceme long, erect, forked at base; scape tall, springing from the root, quite distinct from, and taller than, the leafy stems. (W. O. A. iv. 176.)

C. cardiochilum (cordate-lipped). A variety of *C. Andersonii.*

C. flavescens (yellowish). *fl.* yellow, numerous, produced before the leaves, on a scape 3ft. high. Venezuela, 1895. This species is allied to *C. Andersoni.* (L. x., t. 84.)

C. punctatum splendens (splendid).* *fl.* small, freely produced in tall, branching racemes, and, as well as the upper bracts, coloured yellow, brown, and red. 1893. A pleasing variety, very much in the way of *C. Saintlegerianum.*

C. Saintlegerianum (Saint Leger's). *fl.*, sepals very pale yellow, blotched brown; petals the same colour, with very few spots at the base; lip sulphur, spotted brown, low, rather short, the side laciniæ broad, oblong, margined brown, the middle one small, obtriangular, retuse; column yellow; inflorescence about 2in. long; bracts small. Paraguay, 1885.

C. sanguineum. The correct name is *Cyrtopera sanguinea.*

C. virescens (greenish). *fl.* pale primrose-yellow, blotched with dark red, about 1in. in diameter; sepals ovate, acute; petals rounded; lip fleshy, shortly clawed, the lateral lobes dark red; raceme 1ft. to 2ft. high, many-flowered; scape 2ft. to 4ft. high. December. *l.* narrow-lanceolate, about 1ft. long. Pseudo-bulbs tufted, 3in. to 4in. long, pale green, with narrow purple rings. Brazil, 1893. (B. M. 7396.)

C. cristatum is in cultivation at Kew.

CYRTOSIA. A synonym of **Galeola** (which *see*).

CYRTOSPERMA (from *kyrtos*, curved, and *sperma*, a seed; the seeds are sometimes reniform). ORD. *Aroideæ.* A genus embracing about sixteen species of stove, perennial herbs, with tuberous or elongated rhizomes, inhabiting tropical Asia, Africa, and America. Flowers all fertile on an inappendiculate spadix; spathe ovate-lanceolate or oblong, convolute towards the base, at length opening, the lamina straight or twisted; spadix shorter than the spathe, sessile or stipitate, cylindrical or globose. Leaves hastate; petioles elongated, sheathing at base. The few species introduced require similar culture to that recommended for **Alocasia.**

C. ferox (fierce). *fl.*, spathe greenish-white; scape prickly. *l.* sagittate, borne on prickly petioles. Borneo, 1892. A remarkable species. (I. H. xxxix., t. 153.)

C. Johnstoni (Johnston's). The correct name of the plant described on p. 50, Vol. I., as *Alocasia Johnstoni.*

C. senegalense (Senegalese). *fl.*, spadix dark violet-purple, shortly stipitate, 2in. to 6in. long, ½in. to ¾in. thick; spathe 1ft. to 1½ft. long, oblong-lanceolate, long-acuminate, dull green clouded with red outside, within pale yellow-purple with interrupted bands of maroon-brown. March to May. *l.* 1ft. long, sagittately oblong; nerves many; petioles 3ft. to 4ft. high, sparsely prickly. Upper Guinea, 1897. (B. M. 7617.)

CYRTOSTACHYS. Flowers small, in spirally disposed clusters of three, a female between two males; spathes two, complete, caducous; spadix intrafoliolar, shortly pedunculate, broadly paniculately branched; branches 1ft. to 2ft. long, stout, spreading. Fruit small, ovoid. Leaves pinnatisect; leaflets linear-lanceolate, acuminate, one-ribbed. To the species described on p. 428, Vol. I., the following should be added:

C. Lakka (native name). *fr.* conico-ovoid, ¾in. long, narrowed to the tip. *l.* about 4ft. long; leaflets about 20in. long, 1¼in. broad, the upper ones shorter, obtuse or toothed, green above, ashy-grey beneath; sheath red. Singapore. SYN. *C. L. singaporensis.*

C. ferox (I. H. xxxix., p. 153) has also been introduced.

FIG. 306. FROND OF CYSTOPTERIS BULBIFERA

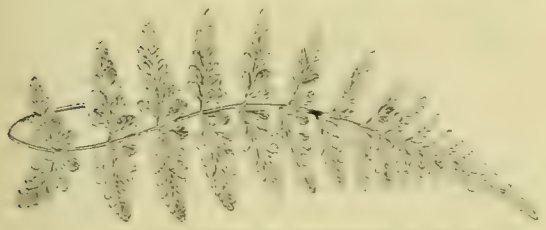

FIG. 307. FROND OF CYSTOPTERIS FRAGILIS.

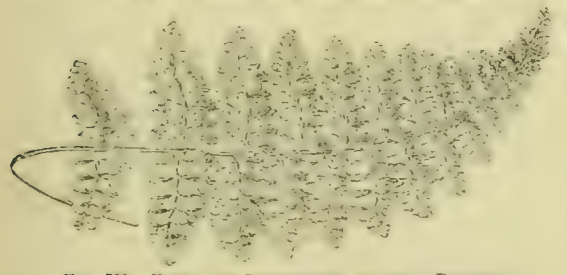

FIG. 308. FROND OF CYSTOPTERIS FRAGILIS DICKIEANA.

FIG. 309. FROND OF CYSTOPTERIS MONTANA.

CYSTOPTERIS. This small genus is interesting, inasmuch as, with the exception of the essentially North American *C. bulbifera* (Fig. 306), all others are indigenous to this country and well adapted for planting in the outdoor Fernery, where shady and well-drained spots should be selected for them, all being found growing naturally at high elevations. *C. fragilis* (Fig. 307) is a common British Fern; while the distinct form, *C. f. Dickieana* (Fig. 308), found by Dr. Dickie near Aberdeen, is by some botanists regarded as of specific rank. *C. montana* (Fig. 309) is provided with underground creeping rhizomes, but all the other Cystopterises produce their slender fronds in great abundance, either from a closely-tufted crown or from shortly-decumbent rhizomes. On account of their delicate appearance, all are well adapted for pot-culture, either under glass, in a cold frame, or without glass protection, in a sheltered position. All the known species and varieties lose their fronds early in the autumn and remain dormant until about April, during which period their crowns must not be allowed to get completely dry. When planted out, a compost of about equal parts fibrous peat, loam, and leaf-mould is the one which suits all Cystopterises best. For pot-culture it is advisable to add to this mixture a small proportion of old, crumbled mortar or broken limestone, and also to pay special attention to the drainage.

The Bladder Ferns are usually propagated during March and April by division of the crowns, wherever more than one has formed; they are also easily raised from spores sown in autumn in a cold frame. *C. bulbifera*, however, is more readily increased by means of the bulbils produced along its rachises, which, having fallen to the ground, soon emit a few slender roots and send up some rudimentary fronds, producing perfectly-developed foliage during the second year.

C. Bergiana (Berg's). A synonym of *Hypolepis Bergiana.*

C. spinulosa (slightly spiny). A synonym of *Asplenium spinulosum.*

C. tenuis (slender). A synonym of *C. fragilis.*

CYSTORCHIS (from *kystis*, a bladder, and *Orchis*). ORD. *Orchideæ.* A small genus (two or three species) of stove, terrestrial, Malayan Orchids. Flowers small, spicate, sub-erect. Leaves petiolate, ovate. *C. javanica* (B. H. 1862, t. 1, f. 1) and *C. variegata* (B. H. 1862, t. 1, f. 5) are in cultivation at Kew, but are of little horticultural value.

CYTHEREA. A synonym of **Calypso** (which *see*).

CYTINACEÆ. A natural order embracing about twenty-two species of broadly dispersed, parasitic, fleshy herbs, of botanical interest, ranking between the *Nepenthaceæ* and the *Aristolochiaceæ*; in some cases they are stemless and consist of flowers only, supported by scales in lieu of leaves, the flowers in *Rafflesia* reaching gigantic proportions.

CYTISUS. Including *Spartothamnus.* The hardy Cytisuses are very accommodating plants, thriving well in rough, turfy loam, but most of the kinds grow freely in dry, sandy soil. Cuttings of half-ripened shoots, dibbled in light soil and placed in a warm propagating-case, root readily. Layering is a quick method of increasing the stock; it should be performed in summer. The dwarf-growing sorts are admirably adapted for rockeries. When planted in dry soils the flowers of *C. purpureus* are light purple, but when grown in damp situations they are deep purple, and much more enduring.

To the species described on pp. 429-30, Vol. I., the following should be added. Several species formerly included here are now referred to **Adenocarpus** and **Genista.**

C. albus multiflorus (many-flowered).* A proliferous garden variety. 1888.

C. Alschingeri (Alschinger's). *fl.* of a pale yellow, freely produced, some of the racemes measuring 1½ft. in length. Croatia. Very floriferous. It is doubtful whether the plant generally cultivated under this name is the true *C. Alschingeri.*

C. Anagyris (Anagyris). A synonym of *Adenocarpus hispanicus.*

C. Andreanus (André's).* A beautiful and distinct variety of the common Broom (*C. scoparius*), having deeper golden flowers, with bright red keels instead of yellow. Found wild in Normandy, 1886. (R. G. 1342; R. H. 1886, p. 372, under name of *Genista Andreana.*)

C. candicans (whitish). *fl.* yellow, in terminal heads, not very numerous. May to July. *fr.* hirsute-villous. *l.* petiolate,

Cytisus—*continued.*

trifoliolate; leaflets obovate, appressedly pubescent. *h.* 6ft. to 9ft. Italy, Orient, &c., 1735. SYN. *Genista candicans* (W. D. B., t. 80).

C. decumbens (decumbent). *fl.* yellow, axillary, erect, long-pedunculate; corolla glabrous. June to August. *fr.* villous. *l.* ovate-oblong, slightly villous beneath. Stem diffuse-prostrate; branches angled, striated, slightly villous. Hungary, &c. SYN. *Genista prostrata.*

C. filifer (thread-bearing). A synonym of *Genista sibirica filifer.*

C. fragrans (fragrant). *fl.* white, very sweet-scented, laterally fascicled. May. *l.* very few, petiolate; leaflets lanceolate, pilose. Branches terete, striated. *h.* 6ft. Teneriffe, 1779. SYN. *Spartium nubigenum.*

C. glabrescens (nearly glabrous). *fl.* bright yellow, axillary, crowded, produced from the same bud with the bundles of leaves, on stalks four times as long as the calyx. May. *l.* having their under-sides and petioles covered with appressed hairs. Stems diffuse. Mountains of Northern Italy, 1896. A small bush.

C. kewensis (Kew).* *fl.* creamy-white, scented, disposed in racemes 1ft. to 1½ft. long, standard large. May. *l.* trifoliolate; petioles (and young branches) softly pubescent. 1896. A pretty and interesting hybrid between *C. Ardoini* and *C. albus*, raised at Kew.

C. linifolius (linear-leafleted). *fl.* yellow, crowded in terminal racemes. January to June. *fr.* hairy. *l.* sessile, trifoliolate, leaflets linear, silky beneath, the margins revolute. South Europe, North Africa, &c., 1739. SYN. *Genista linifolia* (B. M. 442).

C. nigricans Carlieri (Carlier's). This variety continues its growth after the formation of the first set of pods, so that it bears fruits and flowers at the same time. 1891.

C. n. nana (dwarf). A synonym of *C. capitata.*

C. præcox (early).* *fl.* creamy-yellow, produced in great abundance; habit compact. May. A hybrid between *C. purgans* and *C. albus.*

C. purgans (purging). *fl.* yellow, glabrous, axillary, solitary, shortly pedicellate. June and July. *fr.* pubescent when young. *l.* very few, lanceolate, sub-sessile, slightly silky. Branches terete, striated. *h.* 3ft. to 4½ft. France, &c. (B. M. 7618.) SYN. *Genista purgans.*

C. schipkaensis (Shipka Pass). *fl.* white. *h.* 1ft. Balkan Mountains, 1892.

C. supinus (supine), of Crantz and Jacquin. A synonym of *C. biflorus.*

DABŒCIA. This genus embraces only one species—*D. polifolia*, described on p. 430, Vol. I. Seeds should be sown as soon as they are ripe in shallow pans of peaty soil, barely covering them with finely-sifted soil, and placed in a cold frame, or, better still, in a warm greenhouse. The seeds should be sown thinly, and when the seedlings are large enough should be pricked off into boxes of rough peat and leaf-mould, and stood in cold frames, and if never allowed to suffer for water they will be fit for planting out in their permanent quarters the following spring. The following variety is now grown:

D. cantabrica (Cambridge). A synonym of *D. polifolia.*

D. polifolia calyculata (having a large calyx). A very pretty garden variety, producing both white and red flowers, the calyx being so developed as to give the appearance of double blossoms. 1891.

DACRYDIUM. SYN. *Lepidothamnus.* The ten species comprised in this genus are distributed over the Malayan Archipelago and Peninsula, the Fiji Islands, New Caledonia, New Zealand, Tasmania, and Chili. To those described on p. 430, Vol. I., the following species (grown in the Kew Arboretum) should be added:

D. araucaroides (Araucaria-like). *l.* spirally disposed, imbricated, coriaceous, adnate at base, the remaining part free, erecto-incurved, oval-oblong, rounded at apex, convex-keeled at back. Branchlets thick, erect. New Caledonia. A much-branched tree.

D. Colensoi (Colenso's). *l.* variable, some linear and spreading, ¼in. to ½in. long, obtuse, with stout costa, others densely quadrifariously imbricated, triangular, keeled, coriaceous, $\frac{1}{10}$in. to $\frac{1}{15}$in. long. Bark whitish or pale brown with white patches. *h.* 12ft. to 40ft. New Zealand.

D. tetragonum (four-angled). A synonym of *Microcachrys tetragona.*

DACTYLANTHES. Included under **Euphorbia** (which *see*).

DACTYLICAPNOS. Included under **Dicentra** (which *see*).

DACTYLIS CÆSPITOSA. A synonym of **Poa flabellata** (which *see*).

DACTYLOPHYLLUM (of Bentham). Included under **Gilia** (which *see*).

DACTYLOPIUS. A genus of Scale Insects, of which *D. adonidum* and *D. destructor* are found upon numerous greenhouse subjects; and *D. longifilis* upon Ferns and *Euphorbiaceæ.* *See* **Scale Insects.**

DACTYLOSTYLES. A synonym of **Zygostates** (which *see*).

DÆDALACANTHUS (from *dædalos*, of various colours, and *Acanthus*, to which it is related). SYN. *Eranthemum* (in part). ORD. *Acanthaceæ.* A genus comprising fourteen species of stove, erect, glabrous or pubescent shrubs or sub-shrubs, natives of the East Indies and the Malayan Archipelago. Flowers blue, pink (or white?), sessile in the axils of opposite bracts, bibracteolate, forming dense or interrupted spikes; calyx deeply five-lobed or five-parted; corolla tube elongated, slender, incurved above, the limb oblique, spreading, five-lobed; perfect stamens two. Leaves entire or scarcely toothed. *D. macrophyllus* is an erect, minutely pubescent, stove, perennial herb. "It belongs to a class of Acanthaceous plants that are very suitable for winter decoration, flowering freely under proper treatment, which consists very much in careful watering at the time when, in their native country, little or no rain falls" (Sir J. D. Hooker). For culture, *see* **Eranthemum.**

D. macrophyllus (large-leaved). *fl.*, calyx minute; corolla pale violet-blue, 1¼in. to 1½in. long, the limb about ⅔in. in diameter; spikes long-pedunculate, strict, erect, ⅔in. long, narrow; bracts ¼in. to ⅔in. long, loosely imbricated. Winter. *l.* petiolate; lower ones 5in. to 9in. long, elliptic-lanceolate, acuminate, the base decurrent on the petiole, the margins sometimes obscurely serrulate or denticulate. *h.* 2ft. to 3ft. Birma. (B. M. 6686.)

D. nervosus (nerved). The correct name of *Eranthemum pulchellum.*

DÆMONOROPS. The following species, described under *Calamus*, should be transferred to *Dæmonorops*, which is now regarded by botanists as a distinct genus: *C. accedens* (*D. Draco*), *C. adspersus*, *C. Draco*, *C. fissus*, *C. Hystrix*, *C. Jenkinsianus*, *C. Lewisianus*, and *C. verticillaris.* To the species described on pp. 430-1, Vol. I., the following should be added.

D. calicarpus (beautiful-fruited). *fl.*, male spadix 6in. to 16in. long, much-branched; female 4in. to 8in. long; outer spathe 12in. to 16in. long. *fr.* tawny, ⅔in. in diameter. *l.* 6ft. to 8ft. long, the upper ones small; leaflets very numerous, bristle-pointed, 12in. to 13in. long; petioles 1ft. long, with erect spines. Stem erect or somewhat climbing. Malaya.

D. grandis (large). *fl.*, spathe rather thick-fusiform; spadix branches shortened, compact. *l.*, pinnæ equidistant, glaucous, linear-lanceolate, acuminate, unarmed or the margins and keel slightly bristly; petioles gibbous at base. Malacca.

D. intermedius (intermediate). *fl.*, spadix thyrsiform; outer spathe 1½ft. long, the beak twice as long as the body. *l.* 4ft. to 6ft. long; leaflets opposite or scattered, 18in. to 20in. long, 1in. to 1½in. broad, linear-lanceolate, acuminate; petioles 1ft. long, armed with scattered spines. Stem 15ft. to 20ft. high, ⅔in. in diameter. Malaya.

D. longipes (long-stalked). *fl.*, spadix very long, on a long peduncle; spikes 3in. to 5in. long; spathes narrow-lanceolate, scurfy when young. *l.* about 12ft. long; leaflets linear-lanceolate or ensiform, subulate-acuminate, 12in. to 14in. long, 1¼in. broad; petioles convex below and armed with long, irregular spines. Malaya.

D. trichrous is in the Kew Collection, but is not in general cultivation.

DAGGER MOTH. *See* **Pear Insects.**

DAHLIA. These plants are gross feeders, and require a rich, deep soil, if blossoms are to be fully developed. It ought, moreover, to be trenched about 2ft. deep, and during the process a good supply of rich farmyard manure worked in. Trenching should be done in the previous autumn, before the ground is saturated with the autumn rains. In fine weather in winter the surface should be forked over to a depth of 3in. or 4in.; this will allow the air to penetrate more fully into the soil, getting it into the very best condition for planting in the season. At planting-time it is best to put the permanent sticks into the ground. If the soil is in good condition, sufficient should be dug out in front of the sticks to allow of the ball of the roots to go well into the soil. The plants should be firmly inserted, and tied to the sticks at once. If the soil is not in good condition, it is an excellent plan to dig out a spit or two, and

Dahlia—*continued.*

replace it with some prepared soil, such as would be used in re-potting the plants. In favourable weather they will soon grow away vigorously, when all the side-growths ought to be removed except four. These should not be tied up in a bundle—each should have a separate stick to support it; then by careful training a very handsome plant will be produced. As the growths advance they must be tied to the sticks, and the earlier ties must be seen to, as they have a tendency to cut into the succulent growths. When hot, dry weather sets in, water must be applied very freely to the roots, and a mulch of decayed manure will prevent the moisture from too rapidly evaporating. If the very finest blossoms are required for exhibition, it is necessary to shade some of the varieties. Cardboard caps may be put over the flowers, and held in position by a stout stick driven into the ground. To guard against such blossoms being injured by thrips they may be enclosed in a muslin bag.

To the species and varieties described on pp. 432-7, Vol. I., the following should be added:

D. arborea (tree-like). A synonym of *D. excelsa anemonæflora.*

D. excelsa anemonæflora (Anemone-flowered). *fl.-heads* 4in. across; ray florets soft lilac, flat; disk of lilac or yellow, tubular florets. *l.* large, bipinnate; petioles broadly connate. *h.* 12ft. to 20ft. Mexico, 1883. This variety requires to be grown in a cool conservatory. (B. ii. 88; G. C. n. s., xix., p. 60.) SYN. *D. arborea.*

D. gracilis. There are a number of varieties, including *cuprea* (coppery-red), *flore-pleno* (double-flowered), *fulgens* (crimson-scarlet), *ignea* (bright orange), *lutea* (pale yellow), and *superba* (crimson-scarlet, G. C. 1881, xvi., p. 584).

D. Yuarezii. *See* **D. Juarezii.**

D. Zimapani (native name). This is now the correct name of *Bidens atrosanguinea.* SYN. *Cosmos diversifolius atrosanguineus.*

FIG. 310. FLOWER OF SHOW DAHLIA GLOIRE DE LYON.

Varieties. Since the publication of this work proper, some considerable improvement has been wrought in the different sections of the Dahlia recognised by florists. The Pompon and Cactus sections, however, show the greatest advance; while the Singles, at one time so popular, have had to give place to the other sections. The following is a selection of varieties in the different sections. Following the plan of the work, we keep the Show and the Fancies distinct, though, as a matter of fact, the only difference lies in the flowers of the former being self-coloured or practically so; while those of the latter are made up of two or more colours in association.

Show Varieties. AGNES, pure yellow, excellent; ALICE EMILY, nankeen-yellow, good habit; BENDIGO, purple and crimson, fine; CHAMPION ROLLO, deep orange, shaded; CHIEFTAIN, purplish-lilac, large; CLARA, rosy-peach, large; COLONIST, chocolate and fawn; CORONET, dark red, large, good; CRIMSON GLOBE, crimson, large, fine form; DUCHESS OF YORK, lemon, edged with salmon-pink; DUKE OF FIFE, deep cardinal, large, bold flower; ECLIPSE, orange-scarlet, very handsome; GLOIRE DE LYON (Fig. 310), very large, white, of fine form; GLOWWORM, orange-scarlet; HARRISON WEIR, rich yellow; HARRY KEITH, rosy-purple, large and fine; HENRY WALTON, yellow, edged vermilion, very fine; JOHN HICKLING, bright yellow, very fine; JOHN WALKER, splendid white, grand form; J. T. WEST, yellow, edged with purple, fine; KING OF PURPLES, purple, fine form; LE COLOSSE, red, very large; LUSTROUS, rich crimson-scarlet; MABEL STANTON, clear yellow, lovely form; MISS BARBER, white, deeply tipped with purple; MISS CANNELL, white, tipped rose-pink, large and good form; MONT BLANC, pure white, splendid form; MRS. CHARLES NOYES, light fawn, very fine; MRS. LANGTRY, cream, tipped crimson; MRS. S. HIBBERD, white, tipped pink; NORMA, bright orange-buff; NUBIAN, dark crimson; PENELOPE, fawn and amber, tinted yellow, large and fine; PRINCE OF DENMARK, dark maroon, shaded crimson; QUEEN OF THE BELGIANS, delicate cream, inside of petals soft pink, one of the best; RELIANCE, fawn, shaded rose; R. T. RAWLINGS, clear yellow, fine form; SIR CHARLES MILLS, clear yellow; T. S. WARE, crimson; WARRIOR, brilliant scarlet; WILLIAM KEITH, dark plum, large and good; WILLIE GARRATT, bright cardinal, good habit.

Fancy Varieties. BENNETT GOLDNEY, soft terra-cotta, very fine; BLANCHE KEITH, pure yellow, large, and fine form; BUFFALO BILL, buff, striped with vermilion; CÆSAR, soft reddish-scarlet; CHARLES WOODBRIDGE, crimson, shaded with purple, large, full, and of fine form; COMEDIAN, orange ground, flaked with crimson and tipped with white, fine; CRAWLEY GEM, rich crimson-scarlet, small and pretty, fine for cutting; DANDY, orange, striped crimson; DAZZLER, clear yellow, striped with scarlet; DELICATA, soft pink, shading to yellow in the centre; DUKE OF CLARENCE, deep maroon-scarlet, fine and free; EARL OF PEMBROKE, bright plum; EDMUND BOSTON, orange, heavily striped crimson, fine; EMILY GIRDLESTONE, orange-scarlet, grand form; EMIN PASHA, yellow, heavily splashed with crimson, very fine; ENDYMION, clear cerise, fine; ERIC FISHER, buff, striped scarlet; ERNEST CANNELL, soft red, large and fine; ERNEST CHEAL, rosy-scarlet, flowers well above the foliage; ERNEST GLASSE, purplish-magenta, free; FRANCES HUMPHRIES, bright orange, very fine; FRANK PEARCE, bright rose, striped crimson, splendid flower; FUSILIER, coral-pink; GAIETY, yellow, striped red and tipped with white; GENERAL GRANT, orange, chocolate stripes; GLORIOSA, deep red, yellow at base of petals, extra fine; GRAND SULTAN, buff, bright red stripes; HARTIE KING, orange, striped scarlet; J. E. FREWER, vermilion, large and perfect form; JOHN H. ROACH, soft yellow; JOHN WELCH, deep crimson, petals beautifully twisted; LADY PENZANCE, probably the finest of all the yellows; LEONORA, rosy-pink, long, twisted petals, large and good; MARY HILLIER, buff-salmon, very fine; MATCHLESS, velvety-maroon; MATTHEW CAMPBELL, apricot, striped crimson, very fine; MAYOR OF HASTINGS, glowing crimson, very pretty; MAY PICTOR, pale yellow, with long, beautifully-twisted petals, free; MISS ANNIE JONES, crimson, shaded scarlet, petals twisted, free and fine; MISS A. NIGHTINGALE, clear yellow, flushed scarlet; MISS BROWNING, lovely yellow, tipped white, good form; MISS IRENE CANNELL, light pink, shaded with primrose; MISS JANE BASHAM, brick-red, beautifully twisted and pointed petals; MONS. CHAUVIERE, lilac, striped crimson; MRS. A. BECK, reddish-salmon, long and beautifully-twisted petals, free and good; MRS. BARNES, pale primrose, tinged pink, a charming variety; MRS. BENNETT, soft crimson, large and fine form; MRS. C. TURNER, bright yellow, large and floriferous; MRS. GLOVER, rosy-red, shaded orange, dwarf and floriferous; MRS. GORDON SLOANE, pinkish terra-cotta, one of the best for cutting; MRS. H. CANNELL, bright amber, dwarf and free; MRS. JOHN DOWNIE, orange, striped scarlet, very fine; MRS. MONTEFIORE, crimson-scarlet, a large, fine variety; MRS. MORTIMER, yellow, tipped fawn; MRS. N. HALLS, bright scarlet, tipped with white; MRS. WILSON NOBLE, pinkish, free, one of the best; NOVELTY, soft rose, flaked purple and pink; PELICAN, white, striped purple; PLUTARCH, buff, splashed crimson; PORTIA, lilac, striped purple; PRINCE HENRY, lilac, striped purple, good form; PURPLE PRINCE, dwarf and very fine; ROBERT CANNELL, magenta, large, good form; ROYAL GEORGE, soft crimson-pink, fine habit; S. MORTIMER, deep rose, striped purple; ST. CATHERINE, delicate bronzy-amber; SUNSET, yellow, splashed crimson; THE BISHOP, bright coral-red, petals curled and finely-pointed, excellent; T. W. GIRDLESTONE, lilac, splashed maroon, extra fine; VALKYRIE, rich cardinal, one of the earliest.

Bedding and Bouquet or Pompon Varieties. ACHILLES, pale lilac; ADMIRATION, crimson, tipped white, free and pretty; ARTHUR WEST, deep crimson, very fine; BACCHUS, crimson-scarlet, small and neat flower; BELLE OF SPRINGFIELD (*syn.* RYECROFT GLORY), carmine-red, very free and fine; BOULE D'OR, yellow, very pretty; CAPTAIN BOYTON, deep maroon, shaded crimson; CECIL, red, tipped white, fine; CRIMSON KING, dark crimson, very free; DOLLY KEITH, pure white, neat flower; DON JUAN, maroon, small, of perfect form; DR. RAUCH, orange-scarlet; ELI MILLARD, white, petals fimbriated; ERIC, scarlet, tipped and striped white; EVA, rosy-crimson, very pretty; FAIRY TALES, delicate primrose, free and pretty; FASHION, light orange; FLORENCE WOODLAND, yellow, edged crimson, fine form; FLORRIE BURROUGHS, soft purple, edged maroon, very

Dahlia—*continued.*

fine; GEORGE BRINCKMAN, pure white, fine form; GLADYS VALENTINE, delicate blush; GOLDEN GEM, yellow, fine form; GRUSS AN WIEN, crushed strawberry; HECTOR, scarlet, fine; HERMANN KINDELL, fiery scarlet; HILDA, deep rose, tipped and striped white, free; ISABEL, orange-scarlet; JANET, rich salmon; JESSICA, amber, edged red, very pretty; JOHN SPITTLE, pure white, small, fine for cutting; KARL GOLDENBERG, yellow, tipped white; LILIAN, primrose, edged peach, very fine; LITTLE BOBBY, maroon-crimson; LITTLE DUCHESS, white, edged

FIG. 311. FLOWERS OF POMPON DAHLIA LITTLE SWEETHEART.

crimson, very effective; LITTLE SWEETHEART (Fig. 311), red, tipped with white; LOCKET, pure white, shaded with crimson; MARY DRURY, purple-lake, very fine; MIDGET, soft rose, fine; NERISSA, soft rose; OTHELLO, rich crimson; PHŒBE, deep golden, very fine; PURITY, pure white, excellent; RED INDIAN, coral-red, very pretty; RUBENS, maroon, tipped white; ROWENA, yellow, edged scarlet, fine form; RUY BLAS, crimson and purple, tipped white; SAPPHO, rich maroon, crimson; SOVEREIGN, yellow, free and good; THE MIKADO, purplish-crimson, tipped white; TOMMY KEITH, red, tipped white; VIVID, orange-scarlet, good; WHISPER, clear yellow; ZOAR, yellow, edged salmon-pink, very fine.

Single Varieties. ANNIE HUGHES, clear yellow, margined peach, free and good; BEAUTY'S EYE, rich lilac, with deep crimson ring at base of petals, very distinct; CHILWELL BEAUTY, bright chestnut, excellent; DUCHESS OF ALBANY, soft mauve, edged buff; DUCHESS OF FIFE, bright amber, with deep orange band, perfect form; DUCHESS OF WESTMINSTER, pure white, fine form, and floriferous; DUKE OF YORK, orange-scarlet, with yellow ring round disk, fine form; ECLIPSE, rosy-mauve, crimson ring round disk, extra fine; EVELYN, white, edged with pinkish-mauve; FAUST, rich. reddish-crimson, fine form; GULIELMA, pure white, edged buff, perfect form, very free; HARRY BRATEN, deep rose, splashed velvety-maroon, fine; IVANHOE, deep lilac, fine form and substance; JAMES SCOBIE, yellow, striped and spotted red, dwarf and free; KATE, bright orange-maroon, very pretty; KITTY, white, shaded rosy-mauve, charming; K. L. TEMPLE, deep maroon, shaded with carmine, one of the best; LADY HELEN, clear yellow, tipped white; LADY WHITEHEAD, rich rose-purple, with yellow disk, fine; LITTLE SNOW-WHITE, pure white, excellent for cutting; MISS HENSHAW, crimson-scarlet, free; MISS JEFFRIES, mauve and magenta, with broad red ring round disk; NORTHERN STAR, bright red, edged deep yellow, small, very floriferous; SUNNINGDALE WHITE, pure white; T. W. GIRDLESTONE, pure white, edged purple, fine, and useful for

Dahlia—*continued.*

cutting; THOMAS WHEELER, terra-cotta, distinct; W. C. HARVEY, yellow, with red ring round disk, very good.

FIG. 312. FLOWERS OF SINGLE CACTUS DAHLIAS.

Cactus and Semi-Cactus Varieties (see Figs. 312-314). ANTELOPE, rosy scarlet; ARTHUR CHEAL, rich purplish-crimson, fine and very free, flowers well above the foliage;

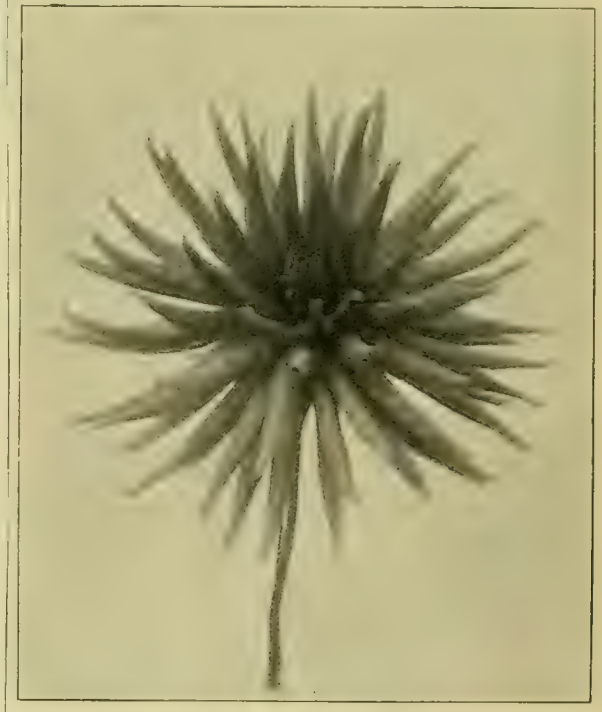

FIG. 313. FLOWER OF CACTUS DAHLIA MISS FINCH.

Dahlia—*continued.*

BEATRICE, pale rose, very fine; BEATRICE MARTIN, white, tinged rose, fine for cutting; COUNTESS OF LONSDALE, purplish-rose, tinged orange, of good habit; EBONY, blackish-maroon, tinted with purple; F. C. PAWLE, rich crimson, tinted with rose, bushy; GREEN'S WHITE, pure white, bushy habit; ISLAND QUEEN, mauve; KEYNES' WHITE, the best white in cultivation; LAVERSTOCK BEAUTY, vermilion, shading to reddish-yellow; LEONORA, bright pink, tinged rose; LOADSTONE, bright orange-red; LUCIUS, orange-red; MAGNIFICENT, orange-buff, shaded rose; MARY SERVICE, shades of heliotrope, pink, and yellow, dwarf; MISS FINCH (Fig. 313), carmine, flushed crimson and purple; MRS. FINDLAY CAMPBELL, orange-scarlet, of excellent form; MRS. HALFORD, rosy-scarlet;

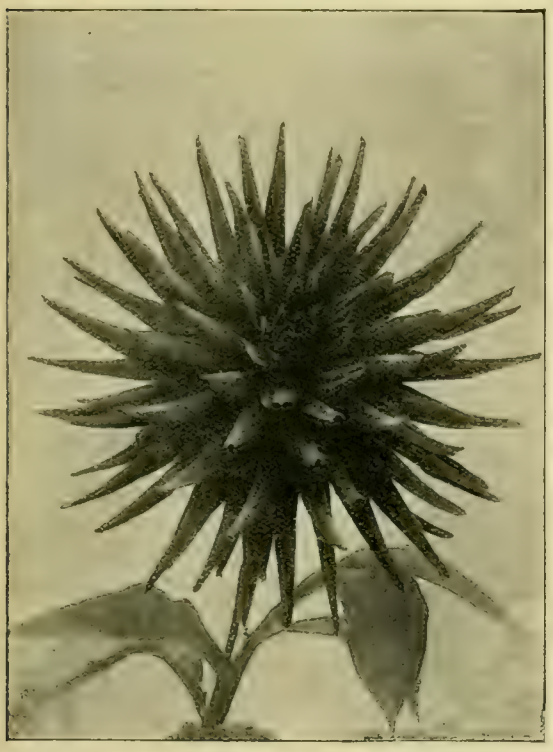

FIG 314. FLOWER OF CACTUS DAHLIA MRS. JOHN GODDARD.

MRS. JOHN GODDARD (Fig. 314); MRS. STEPHENSON CLARKE, yellow, tipped and flushed orange-scarlet; PROGENITOR, glowing scarlet, suffused purple; RANJI, deep maroon; RED ROVER, deep crimson; STARFISH, orange-scarlet, sturdy; SYLPH, orange, handsome; THE CLOWN, deep orange, tipped with white; UNCLE TOM, deep maroon; VISCOUNTESS SHERBROOKE, reddish-terra-cotta, with apricot yellow tinge.

DAHLIA (of Thunberg). A synonym of **Trichocladus** (which *see*).

DALBERGIA. According to the authors of the "Genera Plantarum," this includes *Amerimnon.*

DALEA (of Gærtner). A synonym of **Microdon** (which *see*).

DALIBARDA. Bentham and Hooker include this genus under *Rubus*, and the correct name of *D. repens* is *Rubus Dalibarda.*

DALRYMPLEA. A synonym of **Turpinia** (which *see*).

DAMASONIUM (from *damein*, to conquer; application rather obscure). SYN. *Actinocarpus* (under which name the genus is described on p. 21, Vol. I.). About four species of annual or perennial, stemless herbs are referred here by the authors of the "Genera Plantarum"; two are found in Europe, North Africa, and Western Asia, a third in Australia, and a fourth in California. Flowers white, disposed

Damasonium—*continued.*

in ample, branched racemes or panicles, hermaphrodite; perianth leaflets six, in two series, the three inner ones slender, membranous, and persistent, the outer ones petal-like and deciduous. Leaves all radical, petiolate, ovate, oblong, cordate, or lanceolate, with a prominent midrib.

D. australe (Southern). The correct name of *Actinocarpus minor.*

D. stellatum (star-like). The correct name of *Actinocarpus Damasonium.*

DAMASONIUM (of Schreber). A synonym of **Ottelia** (which *see*).

DAMNACANTHUS. SYN. *Baumannia.* The species of this genus are natives of China, Japan, and the mountains of Eastern Bengal. Flowers white, small, axillary, solitary or in pairs. Fruit red, pea-like. Leaves small, sub-sessile, ovate, acuminate. To the species described on p. 439, Vol. I., the following should be added:

D. indicus (Indian). *fl.* tubular; corolla tube ¼in. long, the segments ¼in. long. Spring. *fr.* 8in. in diameter, borne while the plant is flowering. *l.* opposite, shining green, ¼in. or more in length. Branches slender, with needle-like spines. Japan, &c., 1889. An ornamental, greenhouse or hardy, evergreen shrub.

DAMPING OFF. A disease of seedling plants due to the attacks of a fungus (*Pythium de baryanum*). Prof. Marshall Ward characterises it as "one of the commonest of all maladies found in gardens, occurring in the seed-beds of all kinds of plants in very wet weather, or when the beds are kept too shaded or the seeds have been sown too thickly and kept too moist." At the onset of the attack only a portion of the seedlings appear to be attacked, but gradually the whole of them in seed-bed or seed-pan are involved, and are covered by a white thread-like mycelium. The first symptom that anything is wrong is a characteristic paleness and toppling over of some of the plants, which are attacked just above the soil-line. Such seedlings should at once be removed and burned. As a further preventive measure the same quarters should not be used for seedlings the next season, as the disease is kept alive through winter by means of oospores. Cruciferous plants are very liable to suffer from the disease.

DAMSON MITE (*Bryobia pruni*). A destructive and prolific species of the family *Tetranychidæ*, found, as its common name suggests, upon the Damson. This pest has only been noted within recent years, though doubtless its depredations in the past have been put down to Red Spider, which it somewhat resembles in form, if not in colour. It has eight pairs of legs in the adult state, the front pair being much the longest. Unlike its relative, the **Gooseberry Mite** (which *see*), it spins no web.

The first symptoms of attack are an unhealthy appearance of the leaves, which prematurely yellow. Such leaves, if examined by the aid of a pocket-lens on their under-surface, will be found to harbour numbers of the pests in various stages of development. The mature Mites are reddish-brown; while the larvæ vary considerably as to colour. Prior to the second moult the larvæ are red, and have but six legs. Later the remaining pair is developed, and the colour of the creature undergoes a change. As winter approaches, the larvæ hide beneath the bark or beneath the growths which are allowed to form upon trunk and branches. Here they live in comparative safety, awaiting the advent of the tender young leaves in the spring.

When the Mites are detected the trees should be sprayed with a weak solution of Kerosene Emulsion, sold ready prepared; and in winter, when the trees are at rest, they should be cleansed of Moss and Lichen by the aid of a caustic potash and soda solution sprayed on. *See* **Lichen.**

DANAA. A synonym of **Physospermum** (which *see*).

DANAË (a classical name; Danaë was the daughter of Acrisius, King of Argos, by Eurydice). Syn. *Danaidia.* ORD. *Liliaceæ.* A monotypic genus. The species, *D. Laurus*, is described on p. 335, Vol. III., under its old name, **Ruscus racemosus.**

DANÆA. It is a matter of regret that the requirements of these interesting Ferns should be so little understood. Many importations have taken place within the last few years, but none of the species has become plentiful: the various kinds of treatment have invariably produced unsatisfactory results. Cases after cases of these plants, and

Danæa—*continued.*

FIG. 315. BARREN FROND AND PORTION OF FERTILE FROND OF DANÆA CRISPA.

especially of the beautiful *D. crispa* (see Fig. 315), have reached England in excellent condition, the plants when unpacked being in some instances the very picture of

FIG. 316. FERTILE AND BARREN FRONDS OF DANÆA ELLIPTICA.

Danæa—*continued.*

health; yet none, to our knowledge, have prospered, and the most that has been done with them has been to keep them alive for three or four years, during which time they have gradually dwindled away. Notwithstanding these repeated failures, the beauty of some of the known kinds is such that, should the opportunity of growing them present itself again, they would be well worthy of further trials. They usually come over in their native soil, which appears to be a light yellow, sandy loam of a very porous nature; and they are said to grow naturally in warm, constantly moist, and somewhat close and shady situations. *D. elliptica* (see Fig. 316) is the commonest species.

DANAIDIA. A synonym of **Danae** (which *see*).

DANBYA. A synonym of **Bomarea** (which *see*).

DAPHNE. Including *Mezereum*. The time at which the varieties of *D. Mezereum* are planted is of greater importance than is generally believed. The roots begin to work very early in the year, and transplanting should be carried out in autumn as soon as the leaves have fallen; if this be done in spring, after root-action has commenced, the plants are liable to receive a check. Daphnes should not be planted in a hot, dry, sandy soil: a cool, moist, loamy soil, and an open situation, suit them best. Seeds should be sown in light soil immediately they are gathered, and watered with a fine rose watering-pot, and if placed in a gentle heat germination will take place in a short time; but if the sowing is deferred until spring the seeds become dry, and vegetation takes place very irregularly; besides, they frequently lie dormant in the soil for a couple of years. *D. Laureola* and *D. Mezereum* form admirable stocks for grafting the different varieties upon, which operation should be performed in February or March, placing the stocks in a warm (not hot) propagating-case. It is a good plan to place the stocks in heat a week or so before the operation takes place. Cuttings inserted in moist soil about July, and covered with a bell-glass in heat, root freely. The dwarf-growing varieties are readily increased by layering, also by grafting on fleshy pieces of their own roots in spring. The latter should be plunged in a genial bottom-heat.

To the species and varieties described on pp. 449-1, Vol. I., the following should be added:

D. Blagayana. The flowers of this charming, hardy, European species are shown in Fig. 317. (B. M. 7519.)

D. caucasica (Caucasian). *fl.* white, fragrant, sub-sessile, in terminal clusters of two to twenty; perianth tube ¼in. long, silky-pubescent, the lobes about ¼in. long. May. *l.* 1in. to 1½in. long, linear-lanceolate or oblanceolate, pale green above, slightly glaucous beneath. Caucasus, 1893. A dwarf, hardy, quite glabrous, deciduous shrub. (B. M. 7383.)

D. glomerata (clustered). *fl.* violet-purple, sessile, exceeding the bracts, clustered in umbels amongst the leaves. *l.* lanceolate or oval-lanceolate, about 1in. long, forming a crown to the naked stems. Caucasus, 1891. A dwarf, hardy shrub, something in the way of *D. Blagayana*.

D. indica elegantissima (very elegant). A variety having the leaves broadly margined with white. Japan, 1870.

D. jezoensis (Jezo). *fl.* yellow, fragrant, produced amongst the bases of the leaves, on persistent pedicels; perianth segments spreading, ovate, acute. *l.* obovate-oblong, obtuse, attenuated to a short petiole, pale beneath. Branches highly glabrous, nearly erect. *h.* 2ft. Isle of Jezo, Japan, 1886. A much-branched shrub. (R. G. t. 496, f. 1, 3.)

D. salicifolia (Willow-leaved). A synonym of *D. caucasica*.

D. Mazelii has also been introduced.

DAPHNIDIEÆ. Meissner's name for the species embraced in the genera *Laurus* and *Lindera*.

DAPHNIPHYLLACEÆ. Included under **Euphorbiaceæ** (which *see*).

DAPHNIPHYLLUM (from *Daphne*, and *phyllon*, a leaf; the leaves resemble those of *Daphne*). SYNS. *Goughia*, *Gyrandra*. ORD. *Euphorbiaceæ*. A genus including eleven species of small, glabrous, stove, greenhouse, or hardy, evergreen trees, natives of tropical Asia and the Malayan Archipelago. Flowers apetalous, dicœcious, in axillary racemes; stamens of the males five to eighteen. Leaves alternate, long-petiolate, quite entire, penninerved, usually glaucous beneath. Branches robust, leafy at the tips. Only two species have been introduced. They are evergreen shrubs, quite hardy near London, and thrive under ordinary treatment.

Daphniphyllum—*continued.*

D. glaucescens (glaucous), of gardens. A synonym of *D. macropodum.*

D. jezoense (Jezo). A much dwarfer plant than *D. macropodum*, having the leaves glaucous beneath.

D. macropodum (large-footed). *fl.* borne in short, axillary racemes. Autumn. *fr.* black, about the size of peas. *l.* 6in. to 8in. long, lanceolate, acute, dark green above, paler and more glaucous beneath. *h.* about 6ft. in cultivation (30ft. in its native places). China and Japan. SYN. *D. glaucescens* (of gardens, not of Blume).

DAPHNITIS. A synonym of **Botryceras** (which *see*).

DAPHNOIDEÆ. Included under **Thymelæaceæ** (which *see*).

DAPHNOPSIS. ORD. *Thymelæaceæ.* None of the species of this genus are in cultivation. *Nordmannia cordifolia* has been referred in a gardeners' handbook to *Daphnopsis*, but it belongs to a different natural order (*Boragineæ*), and is really identified with **Trachystemon orientalis** (which *see*).

DASYSTACHYS (from *dasys*, thick, and *stachys*, a spike; in allusion to the dense racemes). ORD. *Liliaceæ.* A genus embracing, according to Mr. J. G. Baker, fifteen species of stove, tuberous-rooted perennials, restricted to tropical Africa, and closely allied to *Chlorophytum.* Flowers white, small; perianth polyphyllous, campanulate; racemes densely many-flowered, usually simple, subspicate; bracts persistent. Leaves radical, linear or lanceolate. For culture of the only species introduced, *see* **Chlorophytum.**

D. drimiopsis (Drimia-like). *fl.*, perianth ⅛in. long, the segments having a brown keel; raceme 3in. to 6in. long, the rachis pubescent; peduncle leafless, 3in. to 12in. long. *l.*, produced ones three, linear, erect, glabrous, 1ft. to 1½ft. long, ¼in. to ½in. broad. Mozambique, 1898. (B. M. 7580.)

DASYSTEMON (of De Candolle). Included under **Crassula** (which *see*).

DASYSTEPHANA. A synonym of **Gentiana** (which *see*).

DASYSTOMA. Included under **Gerardia** (which *see*).

DATE PALM, PRICKLY. *See* **Acanthophœnix.**

FIG. 317. FLOWERS OF DAPHNE BLAGAYANA.

DARWINIA. SYN. *Polyzone.* Including *Francisia.* About twenty-two species of this genus have been described.

DASISTOMA. Included under **Gerardia** (which *see*).

DASURUS. A synonym of **Chamælirium** (which *see*).

DASYAULUS. A synonym of **Bassia** (which *see*).

DASYCHIRA. *See* **Tussock Moths.**

DASYLIRION. About eight species, natives of Mexico-Texan North America, have been referred to this genus. To those described on pp. 442-3, Vol. I., the following should be added:

D. junceum (Rush-like). A garden name for *Agave striata.*

D. quadrangulatum (four-angled). *fl.* small, disposed in a dense, spike-like panicle; flower-stem about 5ft. high. *l.* slender, quadrangular, about 2ft. long. Stem stout, about 3ft. high, crowned with a dense tuft of leaves. Texas, 1887. (R. G. 1887, p. 280.)

D. texanum (Texan). The correct name of *D. graminifolium.* The panicle is 2ft. to 3ft. long.

D. Wheeleri (Wheeler's). Similar in size and habit to *D. texanum*, but with longer, flexuous, usually pendent racemes. *l.* seven to nine lines broad, with brown-tipped teeth. Arizona, &c.

DASYSCYPHA CALYCINA. *See* **Larch Canker.**

DATE, WILD. *See* **Phœnix sylvestris.**

DATURA. This genus embraces about a dozen species, distributed over the warm and temperate regions of the globe. Fruit bristly or smooth. Leaves ample, entire or sinuate-toothed. To the species described on p. 444, Vol. I., the following should be added:

D. aurea (golden). In habit and foliage this does not appear to differ from *D. arborea*, but the flowers are golden-yellow. 1893.

D. chlorantha. The typical species, the double form of which is described in Vol. I., was, according to the "Gardeners' Magazine," introduced in 1894.

D. cornigera Knightii (Knight's). A pretty variety with large, double, white, pendent flowers.

D. cornucopia (cornucopia). *fl.* large and semi-double; interior of the limb very pale lavender, the exterior and the tube lavender profusely spotted with purple. *l.* dark green. 1893. A distinct and handsome form, of dense growth.

D. fastuosa. There are a double-flowered form of this and others called *Huberiana* and *rubra* in gardens; they are probably hybrids.

D. ferox (fierce). *fl.* bluish-white, erect; calyx striated, half as long as the corolla, which is 1½in. long, with an angled limb. August. *l.* ovate-rhomboid, sinuate-repand, toothed. Stem 1ft. to 2ft. high. China, &c., 1731.

D. Knightii (Knight's). A variety of *D. cornigera.*

D. Tatula is a variety of *D. Stramonium.*

DAVALLIA. Including *Odontosoria* and *Synaphlebium*. When grown in either pots or pans, Davallias that are provided with rhizomes require to be a little elevated above the rim of the pot, as nothing is more injurious to them than to have their rhizomes buried in the soil, especially the species whose rhizomes are clothed with large, chaffy scales. Most of them are averse to heavy or close soil, and delight in a compost of three parts fibrous peat, one part chopped sphagnum—or, better still, good leaf-mould—and one part silver-sand, with thorough drainage and an abundant supply of water at the roots during the growing season. During winter they must be watered sparingly, never allowing even deciduous kinds to become quite dry. The plants must not be syringed overhead; but they delight in being kept near the glass. Propagation in the case of those species not producing rhizomes is by spores, sown in heat. Where Davallias like *dissecta*, *bullata*, and *Mariesii* are required in quantity they are best raised from spores. As soon as the seedlings have produced a rhizome 2in. long, this latter is repeatedly pruned, which tends to make compact, bushy plants.

Many Davallias require special treatment. *D. alpina* is one. This requires a warm temperature and moist atmosphere, but without overhead syringing, and to be grown on a pyramid of fibrous peat. *D. bullata* is one of the most useful species in cultivation, succeeding equally well in stove or in greenhouse, and making a very fine specimen, whether grown in a shallow pan of good dimensions, on a pyramid of peat, or on a vertical piece of cork or Tree-Fern stem, where the rhizomes have plenty of room for extension. The Hare's-foot Fern (*D. canariensis*) (Fig. 319) is a very ornamental and interesting species, useful for either pots or for planting on rockwork. Its popular name is derived from the fact that its prostrate stems, which are covered

FIG. 318. DAVALLIA ANGUSTATA.

with pale-brown chaffy scales, have a very close resemblance to the feet of a hare. It also succeeds well under greenhouse treatment, and is an excellent plant for rooms. *D. divaricata* (Fig. 320) is best accommodated on a projecting rock in the warm Fernery. It is a shallow-rooting plant, requiring but a few inches of soil to develop itself to perfection, and on that account may easily be grown on the trunk of a dead Tree-Fern. *D. angustata* (Fig. 318) is a singular little stove species found upon Trees in its native country.

As basket subjects, Davallias are in the first rank. Some of the best are *D. Mariesii* (Fig. 322), *D. fijiensis* and its forms (all of which like peat), *D. canariensis*, *D. immersa*, *D. hirsuta*, *D. marginalis*, *D. retusa*, and *D. bullata*. Sometimes *D. hirsuta* may be accommodated upon the rockery, when it should be placed upon a prominent piece of rock to allow its rhizomes full development. *D. hirta cristata* is one of the strong-growing Davallias which should for preference be grown in fibrous peat and sand only; it is also one of those which suffer most from insufficiency of water at the

Davallia—*continued.*

roots at any time of the year. The whole plant is slightly hairy, and on that account should never be watered overhead. It very seldom produces fertile fronds, and is therefore generally increased by division of the crowns in the early part of the year.

D. pallida is a very attractive species, but its chief merit lies in the fact that it forms a large specimen in a comparatively small pot. Highly decorative, too, and easily grown, is *D. tenuifolia*, but the soil in which it is planted must not contain loam. *D. parvula*, although it grows only a few inches high, is attractive on account of the neatness of its habit. It requires only a very shallow pan, and great care must be taken to keep the whole of the rhizomes above ground. *D. platyphylla* makes an exceedingly handsome specimen when grown in a pot, but it progresses still more rapidly when planted in a substantial compost in the rockery, where an abundance of water can be allowed it during the summer. Another species suited to the rockery is the graceful *D. strigosa*; it requires but little soil. For growing upon a tree-trunk *D. heterophylla* is exceedingly adapted, being a surface-rooter.

D. parallela (Fig. 323) is a minute stove species, which in habit and size resembles our native Polypody.

To the species described on pp. 445-7, Vol. I., the following should be added:

D. aculeata (prickly). *rhiz.* creeping, stout, fibrillose. *sti.* (including rachis) 4ft. to 6ft. long, strong, scandent, spinose-flexuose. *fronds* tripinnatifid; lower pinnæ 1ft. to 1½ft. long, 4in. to 6in. broad, ovate-lanceolate; pinnules lanceolate, 2in. to 3in. long, 1in. broad; segments ¼in. broad, cuneate, deeply two- to four-lobed. *sori* small, cup-shaped, terminal. West Indies. Stove. SYN. *Stenoloma aculeata.*

D. assamica (Assam). *rhiz.* stout, wide-creeping, densely clothed with light brown scales. *sti.* naked, 1in. to 3in. long. *fronds* 6in. to 12in. long, spear-shaped, tripinnatifid; pinnæ shortly stalked; pinnules crowded, naked on both surfaces. *sori* disposed close to the margins of the ultimate lobes; involucres as broad as deep. Bhotan. Stove. SYNS. *Acrophorus assamicus*, *Leucostegia assamica.*

D. brachycarpa (short-fruited). A form of *D. gibberosa.*

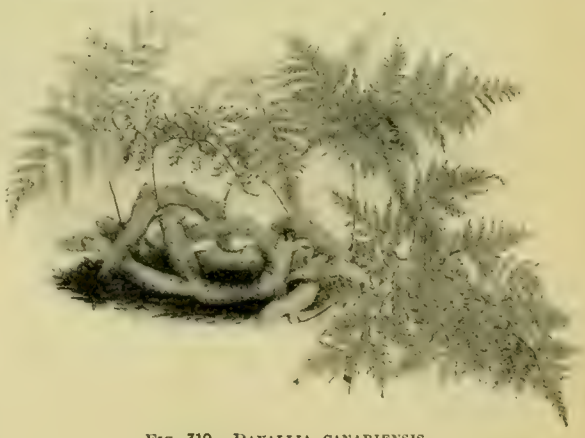

FIG. 319. DAVALLIA CANARIENSIS.

D. ciliata (ciliated). *rhiz.* creeping, densely covered with soft, brown hairs. *sti.* firm, erect, 3in. to 4in. long, hairy. *fronds* 1ft. to 1½ft. long, 6in. to 9in. broad, spear-shaped, tripinnatifid, thin and papery, the rachis and under-surface softly hairy. *sori* very small, disposed two to twelve in a pinnule, and placed near the centre of the teeth near the base. Philippine Islands. Stove. (H. S. F. i., p. 184, t. 60A.) SYN. *Microlepia ciliata.*

D. cristata (crested). A synonym of *C. strigosa.*

D. elata (tall). A form of *D. elegans.*

D. elegans polydactyla (many-fingered). This differs from the type in the many-fingered, dilated apex of the frond, and of the pinnæ, which are all multifidly divided or crested in such a manner as to give the plant an extremely ornamental character. 1882.

D. epiphylla (upon a leaf). This species has fronds more coriaceous than in *D. elegans*, more finely-divided segments, very small sori, and sharp teeth protruded considerably beyond them. Java and the Malayan Peninsula. Stove.

Davallia—*continued.*

FIG. 320. PINNA OF DAVALLIA DIVARICATA.

D. ferruginea (rusty). *sti.* wide-creeping, climbing, not prickly. *fronds* quadripinnatifid; pinnules of the lower pinnæ 2in. to 3in. long, 1in. broad, ovate; segments 1in. long, ⅜in. broad, cut down to the rachis below, the lobes ¼in. to ⅜in. broad, cuneate at base, both deeply-toothed and shallowly crenate. *sori* small, marginal, shallow. Madagascar, 1837. SYN. *Stenoloma ferruginea.*

FIG. 321. UPPER PORTION OF FROND OF DAVALLIA HIRTA CRISTATA.

Davallia—*continued.*

FIG. 322. FROND OF DAVALLIA MARIESII.

D. fijensis elegans (elegant). A pretty variety, lighter-coloured and less dense than the type. 1893.

D. f. major (greater). *fronds* not so finely cut as in the type, borne on slender stalks, and much lighter in colour. Plant more robust.

D. f. plumosa (feathery). In this variety the segments are extremely narrow, and all parts of the frond have a specially graceful, plumose appearance. 1882.

D. fœniculacea (Fennel-like). *sti.* erect, firm, 6in. to 8in. long. *fronds* 9in. to 18in. long, 6in. to 12in. broad, lanceolate-deltoid, quadripinnate; lower pinnules lanceolate, acuminate, 2in. to 3in. long, 1in. broad; segments cut down to the rachis into simple or forked, linear, filiform ultimate divisions one to two lines long, equalling the rachis in breadth. *sori* two to six to a segment, lateral, deeply half-cup-shaped. Fiji Islands, 1885.

FIG. 323. DAVALLIA PARALLELA.

Davallia—*continued.*

D. gibberosa brachycarpa (short-fruited). *sori* as broad as deep, overtopped by a long horn. New Hebrides, 1884.

D. hirsuta (hairy). *rhiz.* slender, creeping, hairy. *sti.* slender, erect, hairy, 3in. to 4in. long. *fronds* abundantly produced, narrow-hastate, 6in. to 9in. long, 2in. broad, tripinnatifid, soft and papery; pinnæ cut down to a broadly-winged rachis into oblong, rather sharply-toothed lobes; both surfaces softly hairy. *sori* two to six to a segment, situated on the marginal teeth. Japan and Tsus-Sima. Greenhouse. SYN. *Microlepia hirsuta.*

Davallia—*continued.*

D. membranulosa (almost membranous). *rhiz.* wide-creeping, stout, densely clothed with pale brown scales. *sti.* 2in. to 3in. long. *fronds* thin, papery, 6in. to 9in. long, 2in. to 3in. broad, once fully pinnate, but the lower pinnæ cut down into numerous sharply-toothed, oblong segments. *sori* two to eight to a segment, obliquely placed between the mid-vein and the margin, Himalayas, Kumaon, &c. Greenhouse. SYN. *Leucostegia membranulosa.*

D. multidentata (many-toothed). *fronds* 2ft. to 3ft. long, 1ft. broad, bipinnate, of a soft, papery texture; pinnules of the lower leaflets cut into egg-shaped segments, each of which bears two to twelve sori at the base of its teeth on the upper side of the central vein. Sikkim Himalaya, &c. A delicate, greenhouse species, having much the appearance of *Asplenium tenuifolium.* SYN. *Leucostegia multidentata.*

FIG. 324. DAVALLIA TENUIFOLIA VEITCHIANA.

D. hirta cristata (crested). *fronds* drooping, beautifully crested. South Sea Islands. See Fig. 321.

D. illustris (remarkable). *rhiz.* stout, creeping, scaly. *sti.* reddish-brown. *fronds* 2½ft. to 4ft. long, arching; pinnæ finely cut. A capital basket plant. 1899.

D. Lorrainii (Lorraine's). *rhiz.* black-scaly. *sti.* 3in. to 4in. long. *fronds* 6in. to 12in. long, deltoid, quadripinnatifid; final lobes ligulate, with a sorus at the base of the inner side. Malay Peninsula, 1882.

D. lucida (clear). A synonym of *D. solida.*

D. ornata (adorned). A form of *D. solida.*

D. polypodioides (Polypodium-like). A synonym of *D. Speluncæ.*

D. pycnocarpa (thick-fruited). A synonym of *D. pentaphylla.*

D. retusa (retuse). A synonym of *Lindsaya retusa.*

Davallia—*continued.*

D. rhomboidea (rhomboid). A form of *D. stylosa.*

D Speluncæ (cavern-loving).* *sti.* strong, 1ft. to 1½ft. long. *fronds* pale green, soft, papery, 3ft. to 6ft. long, 1ft. to 2ft. broad, somewhat triangular, three or four times pinnatifid; lower leaflets 6in. to 12in. long, 3in. to 4in. broad; pinnules spear-shaped, cut to the rachis below into oblong, deeply-toothed lobes. *sori* small, abundant, one or more at the base of each lobe. India, China, &c. A distinct and uncommon, easily-grown, stove species. SYNS. *D. polypodioides, D. trichosticha, Microlepia trichosticha.*

D. tenuifolia Burkei (Burke's). A handsome, delicate, and beautifully-cut form, with fronds hanging down 2ft. or more, and very suitable for basket-culture. 1895.

D. t. stricta (erect). *fronds* more erect, larger, darker, and more coriaceous than in the type.

D. t. Veitchiana (Dr. J. T. Veitch's). *fronds* spreading, plume-like, broadly ovate, quadripinnate; ultimate lobes cuneate, simple or bifid. China, 1883. A handsome basket Fern. See Fig. 324, for which we are indebted to Messrs. James Veitch and Sons.

FIG. 325. DAVALLIA TRICHOMANOIDES.

D. trichomanoides (Trichomanes-like).* *rhiz.* wide-creeping, covered with pale-brown scales. *sti.* grey, naked, 3in. to 6in. long. *fronds* 6in. to 9in. long, elongated-triangular, somewhat coriaceous, quadripinnatifid; pinnæ distinctly stalked, spear-shaped, the lowest and largest 1½in. to 2in. broad; pinnules cut into strap-shaped segments. *sori* showing a horn projecting on both sides. Malay Islands and Ceylon. A very pretty, stove species. See Fig. 325.

D. trichosticha (having hairs disposed in rows). A synonym of *D. Speluncæ.*

D. Truffautiana (Truffaut's). This is described as "a particularly handsome and distinct species, with large, spreading

Davallia—*continued.*

fronds, a peculiarity of which is that the under-surface is like the upper." Peru, 1896. (G. M. 1896, p. 352.)

D. vestita (clothed). *fronds* like those of *D. pedata*, but the barren ones having all their segments, except those of the lower pinnules, blunt and scarcely toothed; lobes of the fertile segments (in the teeth of which the sori are placed) narrower and more sharply toothed. Ceylon and Java. Stove.

DAVID'S HARP. *See* **Polygonatum multiflorum.**

DAVIESIA. To the species described on p. 448, Vol. I., the following should be added:

D. corymbosa (corymbose). *fl.* white, red; standard ¼in. long, racemes usually shorter than the leaves and flowering from above the middle or from the end only. July. *l.* usually lanceolate or linear, rarely broader and oblong, 1½in. to 3in. long. *h.* 2ft. to 5ft. 1804. (A. B. R. 611.) SYNS. *D. glauca* (L. B. C. 43), *D. mimosoides* (B. M. 1957).

D. c. mimosoides (Mimosa-like). *fl.* smaller; racemes flowering from below the middle. *l.* usually narrow, with more pinnate veins. 1809. SYNS. *D. linearis* (L. B. C. 1615), *D. virgata* (B. M. 3196).

D. genistoides (Genista-like). A synonym of *D. ulicina.*

D. glauca (glaucous). A synonym of *D. corymbosa.*

D. linearis (linear). A synonym of *D. corymbosa mimosoides.*

D. mimosoides (Mimosa-like). *See* **D. corymbosa.**

D. ulicifolia (Ulex-leaved). A synonym of *D. ulicina.*

D. ulicina (Ulex-like). *fl.* yellow, solitary or clustered, rarely in umbels of three or four; standard broad. June. *l.* broadly-ovate to lanceolate or linear, pungent-pointed, ¼in. to 1in. long. *h.* 3ft. 1792. (L. B. C. 44; P. M. B. iv. 29.) SYNS. *D. genistoides* (L. B. C. 1552), *D. ulicifolia* (A. B. R. 304).

D. virgata (twiggy). A synonym of *D. corymbosa mimosoides.*

DEADLY CARROT. *See* **Thapsia.**

DEAL, WHITE. *See* **Picea excelsa.**

DEAL, YELLOW or RED. *See* **Pinus sylvestris.**

DEATH'S HERB. *See* **Atropa Belladonna.**

DEBRÆA. A synonym of **Erisma** (which *see*).

DEBREGEASIA (derivation not stated, but probably commemorative). SYN. *Morocarpus.* ORD. *Urticaceæ.* A small genus (five species) of stove or greenhouse shrubs or trees, natives of tropical and sub-tropical Asia and Africa. Flowers monœcious or dicœcious, in capitate, sessile, panicled or spicate clusters; males having three to five sepals and petals; females having a fleshy receptacle and an ovoid or obovoid perianth, succulent in fruit. Leaves alternate, serrated, three-nerved; stipules bifid. Only one species has been introduced. It requires ordinary greenhouse treatment.

D. velutina (velvety). *fl.*, sepals four; heads in short, dichotomous cymes. *fr.* red or yellow, about the size of a pea, in shortly-stalked heads. *l.* stalked, linear- or oblong-lanceolate, acuminate, serrulated, rounded at base, 4in. to 7in. long, smooth or scabrid above, white- or ashy-tomentose beneath. *h.* 6ft. to 9ft. Sub-tropical Himalaya, &c., 1896. (R. H. 1896, p. 321, f. 118.)

DECABELONE. This genus includes three species, one being a native of Angola and the others South African. Flowers large, solitary or twin, shortly pedicellate; calyx segments five, acute; corolla tubular-campanulate, slightly incurved, marbled and spotted within, broadly five-lobed; corona duplex, the outer one of ten lobes, the inner of five scales. Stems dwarf, with six to twelve very elevated ribs.

DECAISNEA. To the species described on p. 449, Vol. I., the following should be added:

D. Fargesii (Farge's). *fl.* in axillary, loosely paniculate, erect racemes; pedicels much shorter than the flowers. *fr.* azure-blue, pendent, cylindrical. *l.* long-petiolate; leaflets six to ten pairs, stalked, membranous, ovate-lanceolate, acuminate, entire, glaucous, slightly powdered. Su-tchuen. Plant woody, erect, with fragile branches.

DECAISNEA (of Brongniart). A synonym of **Prescottia** (which *see*).

DECAISNEA (of Lindley). A synonym of **Tropidia** (which *see*).

DECASCHISTIA (from *deka*, ten, *schistos*, divided; in allusion to the ten bractcoles, the ten-celled ovary, the ten-branched style, and the ten-valved capsule). ORD. *Malvaceæ*. A small genus (four or five species) of stove shrubs, natives of India and Birma. Flowers shortly pedunculate, axillary or clustered and terminal; sepals and petals five, connate below, the latter adnate to the tube of the stamens; bracteoles ten. Leaves entire or lobed. Only one species has been introduced. For culture, *see* **Hibiscus.**

D. ficifolia (Ficus-leaved). *fl.* coppery-red, merging into yellow, with a rosy spot at the base, 3in. or more in diameter. *l.* three-lobed, cuneate at base; lobes toothed, hoary beneath. Birma, 1888. A handsome shrub.

DECASPERMUM. A synonym of **Nelitris** (which *see*).

DECASPORA. A synonym of **Trochocarpa** (which *see*).

DECODON. Included under **Nesæa** (which *see*).

DECOSTEA. A synonym of **Griselinia** (which *see*).

DECUMARIA. *Forsythia* (of Walter) is identical with this genus.

DEER GRASS. *See* **Rhexia virginica.**

DEFINITE. Constant, fixed, or limited in number; stamens are said to be Definite when they do not exceed a score.

DELAIRIA SCANDENS. A synonym of **Senecio mikanioides** (which *see*).

DELIMA. *Leontoglossum* is synonymous with this monotypic genus.

DELPHINIUM. This genus comprises about forty species, distributed over the North temperate zone. For the herbaceous border there are no brighter or more easily grown plants than the hybrid perennial Larkspurs, provided the soil is fairly rich and there is an abundance of water during the growing season. After the first flush of beauty is over, it is a good plan to cut the plants right down. Further blossoms will then be produced, which, if not so fine as those first seen, will tend to prolong the season of beauty of these useful, hardy plants. These Delphiniums should be planted in early spring, and whether used in the border, as already suggested, in the beds, or in the shrubbery, they are equally effective when in flower. When planting the crown should be kept about 2in. beneath the surface.

To the species and varieties described on pp. 450-1, Vol. I., the following should be added:

D. armeniacum (Armenian). *fl.* azure-blue. Armenia, 1894. This plant closely resembles *D. Ajacis*, but is more robust.

D. azureum album (white). *fl.* creamy-white, in long, wand-like racemes. *l.* large, deeply three- to five-parted, the divisions cleft into narrow lobes. Stems 2ft. to 3ft. high. North America, 1832.

D. cashmirianum Walkeri (Walker's).* *fl.* 1in. or more in diameter; sepals pale blue, striped with darker blue; petals dull yellowish, tipped with brown; peduncles 3in. to 4in. long, one-flowered. *l.* orbicular, three- to five-lobed; lobes lobulate. Kashmir, 1885. A dwarf, rockwork plant. (B. M. 6830.)

D. caucasicum (Caucasian). *fl.* blue; spur slightly incurved, about as long as the hairy sepals; peduncles long. *l.* long-petiolate, 1½in. across, cordate-orbicular, tripartite; segments ovate, obtuse, incisely lobed. Stems 3in. to 4in. high, sparsely hairy, three- or four-flowered. Caucasus, 1880. There is a variety *dasyanthum*, rather larger than the type.

D. chinense (Chinese). A variety of *D. grandiflorum*.

D. corymbosum (corymbose). *fl.* densely racemose; sepals pale violet, petaloid; petals almost black, the upper one erect, the lower spreading, bifid, bearded. *l.*, lower ones palmately five-lobed, hairy on both sides, the lobes repeatedly three-lobed; upper cauline ones petiolate or sessile, palmately five-lobed. Stems corymbosely branched. *h.* 1ft. to 1½ft. Eastern Turkestan. (R. G. 1059.)

D. denudatum (denuded). *fl.* nearly 1in. long, many, in much-branched racemes; sepals yellow, with blue margins; petals pale blue. *l.*, radical ones 2in. to 6in. in diameter, orbicular, five- to nine-partite, the segments bipinnatifid; cauline ones few, the uppermost ones tripartite. Stem branched, 2ft. to 3ft. high. Temperate Himalayas, 1870

Delphinium—*continued.*

D. hybridum sulphureum (sulphur). A synonym of *D. Zalil.*

D. nudicaule aurantiacum (orange-coloured). A garden variety. 1883.

D. Nuttalli (Nuttall's).* *fl.* white, with sky-blue spots on the upper segments, produced in branching spikes occupying about one-third of the scapes. *h.* 2ft. to 2½ft. North America.

D. peregrinum (foreign). *fl.* blue; spur ascending, twice as long as the rest of the flower. July. *l.* tripartite, the segments linear-lanceolate. Branches straight. *h.* 1ft. North Italy, &c., 1629.

D. speciosum glabratum (showy, glabrous). This is similar in growth and flowers to *D. cashmirianum*, but has larger inflorescences, and the flowers have longer spurs. Himalayas, 1897.

D. sutchuenense (Su-tchuen). A synonym of *D. cheilanthum.*

D. tatsiensis (Ta-tsien-lu). *fl.* cobalt-blue. *l.* much smaller than in *D. cheilanthum* (to which this species is allied). *h.* 2ft. China, 1896.

D. trolliifolium (Trollius-leaved). *fl.* bright blue, 1in. to 1½in. broad; spur as long as the sepals; raceme loose, few-flowered, with rather long pedicels. *l.* long-petiolate, five- to seven-lobed; lobes laciniately cleft and toothed, with acuminate segments. Stems stout, 2ft. to 4ft. high, glabrous or slightly hairy. Oregon, 1889.

D. viride (green). *fl.* loosely racemose; sepals and the long, stout spur yellowish-green; petals deep purple. *l.* palmately cut and toothed. Chihuahua, 1888. Annual or biennial. (G. & F. 1888, i., pp. 149-50, f. 29.)

D. Zalil (Zalil).* *fl.* pale yellow, rather larger than a shilling, disposed in long racemes. May to August. *l.* dark green, finely cut. Stem branching; branches 8in. to 16in. long. Afghanistan, 1887. An attractive annual, the flowers of which are extensively used, especially in Persia, for dyeing silk. (B. M. 7049.) SYN. *D. hybridum sulphureum.*

Varieties. These are now very numerous, and are far superior in colour-range and general effectiveness to the older garden kinds. The following is a good selection, varying from pale blue to deep purple, and all of stately growth:

ALBERT EDWARD, deep plum, black eye; ALFRED HENDERSON, violet, white centre; ASPIRATION, rich violet, white eye, semi-double; BANQUO, violet-purple, black eye; BASSANIO, violet, semi-double; BEAUTY, pale blue, white eye; BRITANNIA, very deep blue, large white eye; CETO, sky-blue, semi-double; CLARA STUBBS, deep blue, white centre; DAVID, deep blue, black eye; DUKE OF CONNAUGHT, bright blue, dark eye; DUKE OF TECK, bright blue, white eye; EVELYN, dark blue, edged lighter blue, semi-double; FRANK HOLL, deep blue, white centre; GAINSBOROUGH, deep blue, with violet inner petals, semi-double; GENEVA, sky-blue, white eye, semi-double; HENRY, deep blue and purple, white eye; HORACE, violet-purple, white eye; JAMES KELWAY, violet-blue, white eye; J. S. SARGENT, deep blue, shading to plum, with dark eye; KING OF DELPHINIUMS, rich deep blue, white eye, semi-double; LADY ESTHER GORE, azure-blue, white eye; MONUMENT, lavender, darker centre, semi-double; MR. CROMPTON ROBERTS, rich purple and deep blue in combination, with dark eye; MRS. RUSHTON, bright blue, veined rose, white centre; SARA, sky-blue, pink veinings and white centre; SIR JOHN FORREST, dark blue and violet-purple, creamy-white eye; SIR WALTER SCOTT, purple and blue, dark eye; TRUE BLUE, gentian-blue, black eye.

DELTOIDES. *See* **Snout Moths.**

DEMATIEI. *See* **Mould.**

DEMETRIA. A synonym of **Grindelia** (which *see*).

DEMIDOVIA. A synonym of **Tetragonia** (which *see*).

DENDRAGROSTIS. A synonym of **Chusquea** (which *see*).

DENDRIUM. A synonym of **Leiophyllum** (which *see*).

DENDROBIUM. SYNS. *Callista*, *Ceraia*, *Desmotrichum*, *Onychium* (of Blume). Including *Aporum*. This genus is here revised in accordance with the admirable monograph published by Messrs. James Veitch and Sons, in Part III. of their "Manual of Orchidaceous Plants."

None of the Eastern genera of Orchids have gained so much prominence of late years as the various species and hybrids belonging to the deciduous section of Dendrobiums, and certainly none are worthier of consideration. The numerous hybrids, especially new introductions, which have been derived from the intercrossing of the various species,

Dendrobium—*continued.*

are always sought after. These are now extensively grown for cut-flower purposes. The exhibition tables also are adorned profusely with these gems during the early spring months of the year.

With the more extensive cultivation of Dendrobiums, it is pleasing to note that many of the "old fads," such as growing the plants on blocks, the absolute necessity of using charcoal for drainage, the hard-and-fast rules for damping the houses, watering, and their barbarous treatment during the resting season, are things of the past. Under the more generous and practical methods now adopted this section of plants is now grown far more easily and with better results than was the case in the past.

The requirements now generally accepted in the successful culture of deciduous Dendrobiums are—first, to place the plants in as small a receptacle as possible, so that very little compost indeed is required, and that consisting of fibrous peat, with the whole of the dust extracted, and chopped living sphagnum in equal portions; secondly, to pot immediately after the plants have flowered and are commencing to emit new roots from the base of the growth; and, thirdly, to give every encouragement to induce rapid and vigorous growth. The whole section requires any amount of strong light throughout the year. Only sufficient shade is required to prevent actual scorching of the foliage. In such conditions, and by maintaining during the day a high temperature in the house without resorting to fire-heat, rapid growth may be ensured. During the summer, at night only will fire-heat be necessary. In bright weather the plants may be liberally syringed, and every measure used to keep the atmosphere at the saturation point. The plants may also be watered whenever they become anything like dry.

The lower ventilators should be brought into use early in the day, and closed again as soon as possible after the middle of the day. As soon as this has been done, and the outside conditions are favourable, the whole of the plants should be given a thorough syringing overhead. This operation should always be done sufficiently early to enable the foliage to become dry before the cool evening, with a lowering temperature, arrives. These conditions should be maintained until the growth has matured; after which the plants should be gradually removed to cooler and drier quarters, where they may have an abundance of air and every inducement given to enable them to properly ripen their growths.

During the season of rest only sufficient water will be required to maintain the bulbs in a plump condition. When any indication of the shrivelling of the bulbs is observed, such plants should be dipped in water, which induces them to plump up readily, and they soon regain their normal condition. The proper maturing or ripening of the growths is one of the principal requirements for the satisfactory flowering and for the future well-being of the plants. It is not desirable to place the plants into heat too soon after they commence to push their flower-buds, as they are sometimes thereby induced to turn their flower-buds into side-shoots. They should be gradually brought into their flowering quarters, and more liberal conditions provided until the flower-buds can be defined, when they should have every encouragement to induce them to expand their flowers.

This section may be easily propagated, if it is desirable to increase the stock, by the cutting off of any of the back bulbs that possess nodes or eyes which have not flowered, and placing them in a basket of sphagnum, or by laying them on cocoa-nut fibre in the propagating case. The breaks are produced from the side eyes: when the breaks get well away, root action commences at the base. They may then be removed by carefully cutting away a small portion of the old bulb with the new growth, and potting them up in the usual way. The potting compost should consist of finely-chopped sphagnum and rough sand. Every encouragement must then be given by heat and moisture to induce a free growth.

The extensive importations of the lovely *D. Phalænopsis* has placed this noble species within the reach of all. The variable characteristics have been enormous, and are now so familiar that they need no description here. *D. Johnsonæ*, the lovely *D. atroviolaceum*, and others, of what may be termed the New Guinea section of Dendrobiums, have also been extensively imported. These must be kept in the warm division throughout the year. Little moisture

Dendrobium—*continued.*

will be required at the roots during the rooting season: only sufficient should be given to maintain the bulbs in a plump condition. With the evergreen section very few additions have been made, and those do well under the conditions previously advised for this class.

To the species, varieties, and hybrids described on pp. 452-8, Vol. I., the following should be added:

D. æmulum (emulous). *fl.* white, fragrant, 1½in. across, the apical half of the segments sometimes stained pale yellow; sepals narrow-lanceolate; petals linear; lip very short, three-lobed, the side lobes acute, spotted pink, the middle one reflexed; racemes terminal, lax, five- to seven-flowered. Stems terete, 2in. to 4in. or more in length, sometimes tapering to a long, thin base with a small pseudo-bulb, and bearing at their summit two or three very coriaceous leaves. Australia. (B. M. 2906; F. A. O., i., part ii. 5; G. C. 1895, i., p. 434.)

D. amboinense (Amboyna). *fl.* in pairs; sepals and petals creamy-white, spreading, nearly 3in. long, linear-lanceolate; lip small, yellowish, edged with dark purple. *l.* terminal, oblong, acute. Stems jointed, bulbiform at the very base, four- to six-angled above. Amboyna, 1856 and 1895. A very singular species. (B. M. 4937; F. d. S. 1211.)

D. amethystoglossum (amethyst-lipped). *fl.* ivory-white, except the amethyst-purple anterior lobe of the lip, crowded, about 1in. in diameter; sepals and petals ovate-oblong, acute; lip elongated, linear-spathulate, apiculate, convex in the middle, incurved at the margins except towards the apex; spur long, obtuse; column exposed; racemes 3in. to 5in. long, many-flowered. January and February. *l.* sessile, oval-oblong, subacute. Stems robust, sometimes 2ft. to 3ft. high and nearly 1in. thick. Philippine Islands, 1872. (B. M. 5968.)

D. anceps (two-edged). *fl.* greenish or yellowish, ½in. long, axillary, very shortly pedicellate; mentum longer than the sepals; lip cuneate-oblong, obscurely three-lobed. *l.* 1in. to 1½in. long, lanceolate or ovate-lanceolate, acute. Stem 1ft. to 3ft. long, stout, flattened. India. SYN. *Aporum anceps* (B. M. 3605; B. R. 1239; L. B. C. 1875).

D. anosmum (scentless). A form of *D. superbum.*

D. Antelope (antelope-horned). *fl.* yellowish; sepals ligulate-triangular, acute; petals long, antenniform, upright, painted sepia inside; lip striped and speckled mauve, the square anterior lacinia having its abrupt apiculus short. Moluccas, 1883.

D. arachnites (cobwebby). *fl.* bright cinnabar-red, in fascicles of two or three, but sometimes solitary, 2½in. across when spread out; sepals and petals linear, acute; lip veined purple, shorter than the other segments, sub-pandurate, convolute over the column at the base; column very short. *l.* linear-lanceolate, acute, 1½in. to 2½in. long. Stems terete, 2in. to 3in. long. Moulmein, 1874. Very rare in cultivation.

D. atropurpureum (dark purple). *fl.* yellowish or pink, about ½in. long, sub-sessile in axillary, shortly peduncled, bracteate heads; mentum as long as the sepals; lip thick. *l.* 1in. to 1½in. long, variable. Stem 4in. to 6in. long. Tenasserim, &c.

D. atroviolaceum (dark violet).* *fl.*, sepals and petals creamy-white, spotted with deep purple; lip violet-purple inside, green outside, three-lobed; spike terminal, erect. Spring. Pseudo-bulbs tapering downwards, persistent, with two or three stout, leathery leaves near the apex. New Guinea, 1890. (B. M. 7371; G. C. 1894, xv., p. 113, f. 12; J. H. 1894, xviii., p. 65, f. 10; W. O. A. x., t. 444.)

D. Augustæ Victoriæ (Augusta Victoria's). A synonym of *D. veratrifolium.*

D. aurantiacum (orange). A synonym of *D. aureum aurantiacum.*

D. aureum album (white). *fl.* very pale, nearly white. A flower of the typical species is shown in Fig. 326.

D. a. aurantiacum (orange). *fl.* orange-yellow. The richest-coloured of all the varieties. SYN. *D. aurantiacum.*

D. a. Henshalli (Henshall's). *fl.*, lip white, suffused yellow at base, where there are two reddish-purple spots. (B. M. 4970, under name of *D. heterocarpum Henshalli.*)

D. a. pallidum (pale). *fl.* sometimes smaller than in the type; lip white, with the exception of a yellow stain at base. Stems longer and slenderer. (B. R. 1839, t. 20.)

D. barbatum (bearded). *fl.* white; lip three-lobed, edged with long, flexuous hairs; racemes terminal, short, four- or five-flowered. Pseudo-bulbs bearing six or seven lanceolate-linear leaves. Birma, 1897. Allied to *D. ciliatum.*

D. bicameratum (twice-arched). *fl.* yellow, with red speckles arranged in stripes, ¼in. broad, crowded on a short, sheathed peduncle; lip golden-yellow. *l.* linear-lanceolate, 3in. to 4in. long, obliquely bifid. Stem clavate, fusiform, or elongate and 1ft. to 1½ft. long. Sikkim Himalaya, 1837. Plant variable (Ref. B. 143.) SYN. *D. brevifforum.*

Dendrobium—*continued.*

FIG. 326. FLOWER OF DENDROBIUM AUREUM.

D. bigibbum albo-marginatum (white-margined). A variety having whitish edges to the flowers. 1892. (L. vii., t. 317.)

D. bracteosum (bracteate). *fl.* purple, with a yellow lip, marked reddish on the front margins, grouped in capitate masses; sepals triangular, keeled, the spur about two-fifths the length of the free part of the lateral sepals, rather blunt; petals narrower, oblong, acute; lip nearly spathulate, a little convex on the upper sides, much thicker at the base; bracts nearly as long as the flowers. New Guinea, 1886. (L. ii. 74.) SYN. *D. chrysolabrum.*

D. breviflorum (short-flowered). A synonym of *D. bicameratum.*

D. brisbanense (Brisbane). A synonym of *D. gracilicaule.*

FIG. 327. FLOWER OF DENDROBIUM BRYMERIANUM.

D. Brymerianum histrionicum (actor). *fl.*, lip having "sometimes a beard, sometimes none, like a comedian." Autumn. A flower of the typical species is shown in Fig. 327.

D. calamiforme (quill-like). A synonym of *D. teretifolium.*

D. Calceolaria (Calceolaria-like). This is the correct name of *D. moschatum.*

D. capillipes (hair-stemmed). *fl.* bright golden-yellow, in short racemes. *h.* 6in. Moulmein. A curious species, resembling a pigmy form of *D. albo-sanguineum.* It succeeds on a block or in a basket. (R. X. O. ii. 169, f. 4-6.)

D. cariniferum lateritium (brick-red). *fl.*, sepals light yellow; petals white; lip brick-red, with a yellowish front lobe. 1883.

D. c. Wattii is now classed as a species.

Dendrobium—*continued.*
